"Such, however, is the present spirit and speculation of this country, that wherever the demon of gain raises his banner, talents and exertion are sure to follow it. Cotton mills are as yet but in their infancy. Whilst great profits and immense fortunes are to be made by them, we know they must rapidly increase; and it is too obvious that, without public attention, they must be destructive of the moral and religious principles of the great mass of the people. The effect of this species of abridgment of labour is so great, that 100 persons in a cotton mill, will do more spinning, and that of ten times the fineness, and of a superior quality, to what can be produced by 3000 of the very best spinners by hand. In consequence of this, cotton mills have almost entirely deprived the cottager's wife and children of their means of domestic industry. The profit of spinning by hand is so reduced, that whole districts of cottagers' families have been obliged to give it up, and apply for relief to the parish.

"Our national and individual increase of wealth, from the manufacture of cotton, has been attended with so much injury to the health and morals of the poor, and is so utterly

destructive of that which constitutes the essential and fundamental virtue of the female character, that if I am not permitted to suggest a doubt, whether it would not have been better for us that cotton mills had never been erected in this island, I may at least express an anxious wish, that such regulations may be adopted and enforced, as shall diminish, if not entirely remove, the injurious and pernicious effects which must otherwise attend them.

"With this view I will lay before the reader an outline of some regulations, which, impelled by zeal, but very little presuming on personal knowledge of the subject, I venture to submit to the consideration of the public: meaning to apply my observations, not merely to cotton mills, but to all other manufactories under similar circumstances; and particularly to those, in which children are engaged as apprentices.

"In the first place, I conceive that some general and public attention ought to be paid to the moral and religious improvement of so numerous a class of our fellow-subjects: and that the most essential parts of their education ought not entirely to depend on the caprice, or disposition, of their respective masters; especially as many of them have been apprenticed by lots from distant counties, and have been deserted by those, whose duty it was to have protected them. In addition to this, something should also be done for the benefit of these children, to instruct and prepare them to support themselves in life, without thievery and prostitution, when the period of their apprenticeship expires at the age of sixteen.

"It seems to me to be also expedient that the age and conditions of apprenticeship be regulated;—that the hours of work be limited, and night-work (so destructive to health and morals) entirely excluded;—that a total separation take place between the boys and the girls;—that the works be liable to the periodical inspection of the magistrates, who should have power to order the regular white-washing and cleaning, and the warming and ventilating of the work-rooms; and who should receive quarterly or monthly reports, from each manufactory, of the number, the health, and the respective ages, of all the apprentices and other persons employed there.

"Such are the regulations, which, upon a cursory view of the subject, appear to be proper, and to have a tendency to meliorate the condition, and to preserve the morals, of these unfortunate and neglected children. Other correctives and remedies may probably occur to those who possess more practical knowledge of the subject. At present I have only to add that, as far as my enquiries have extended, I have reason to be satisfied, that almost all the owners of cotton mills will concur in thinking, that the preceding, or some similar, regulations ought to be enforced by the legislature, for the protection of the children employed in those mills. In order therefore that something practicable and effectual may be done, without injury to the interest of the manufacturers, I would suggest that the outline of any regulations proposed to be adopted, should be first communicated to them, so that they might state any objections, or amendments; and after a proper attention shall have been paid to their observations, I venture boldly to express my confidence, that the measures will have the support of every one, who desires to promote the welfare and happiness of his fellow-creatures, and the essential interests of virtue, morality, and religion, in this favoured country."

COUCY, a town of France, in the department of Aisne, nine miles N. of Soissons. Long. 3. 13. E. Lat. 48. 30. N.

COVERDEN, a town of the United Provinces, in Overijssel, with a fortress in the marshes, strong both by nature and art. It is thirty-five miles N.E. of Deventer. Long. 6. 35. E. Lat. 52. 46. N.

COULAN, or QUILON, a country of the peninsula of

Hindooftan, on the coast of Malabar. The inhabitants are generally Gentooes, with some Christians of St. Thomas. The capital is of the same name, where the Dutch have a settlement. Long. 75. 30. E. Lat. 8. 30. N.

COUSERANS, a late province of France, lying along the river Satat, and forming, with Foix, the department of Arrège.

COUTRAS, a town of France in the department of Dordogne, and late province of Périgord; seated on the Dordogne, twenty miles N.E. of Bourdeaux. Long. 0. 3. W. Lat. 40. 4. N.

COW (Encycl.). For proofs of the advantage which the poor cottager may derive from keeping a cow. See the article COTTAGER in this supplement.

COWBRIDGE, a small but neat town of Glamorganhire, with a market on Tuesday. It is called by the Welch Pont-Van, from the stone bridge over the river, which soon after falls into the sea. The streets are broad and paved; it is governed by two bailiffs, twelve aldermen, and twelve common-council; and here the assizes for the county are held. It is twelve miles W. of Cardiff, and 176 W. of London. Long. 3. 33. W. Lat. 51. 28. N.

COWPER (William), a modern poet of distinguished and original genius, was born in 1732, at Berkhamstead in Hertfordshire. His father, the rector of the parish, was John Cowper, D.D. nephew to Lord Chancellor Cowper. Mr. Cowper was educated at Westminster school, and at that seminary he acquired the classical knowledge and correctness of taste for which it is celebrated, but without any portion of the confident and undaunted spirit which is supposed to be one of the most valuable acquisitions derived from great schools to those who are to push their way in the world. It appears, indeed, from his poem, entitled Tirocinium, that the impressions made on his mind from what he witnessed, were of the most unfavourable kind, and gave him a permanent dislike to the system of public education. As through family interest the honourable and lucrative place of clerk to the House of Lords had been provided for him, he was entered at the Temple for the study of the law, in order to qualify him for it. In this situation his manners were amiable and decent; and though it is probable that he did not refuse to indulge in those pleasures which are usual among young men similarly situated, yet there seems no reason to suppose that he had any peculiar causes for self-accusation. His natural disposition was timid and diffident; his spirits were constitutionally weak, even to the borders of absolute uselessness for worldly concerns; so that when the time came for assuming that post to which he had been destined, he shrunk with such terror from the idea of making his appearance before the most august assembly in the nation, that, after a violent struggle with himself, he actually resigned the employment, and with it all his prospects in life. It appears to have been under the agitation of mind which this circumstance occasioned, and which threw him into a serious illness, that he was led to a deep consideration of his state in a religious view; and from the system he had adopted, this course of reflection excited in him the most alarming and distressful apprehensions. In vain did his theological friends set before him those encouraging views which the theory of Christian justification is calculated to present, and which to many is the source of a confidence perhaps as excessive as their former fears; the natural disposition of his mind fitted it to receive all the horrors, without the consolations, of his faith. We are told, that "the terror of eternal judgment overpowered and wholly disordered his faculties; and he remained seven months in a continual expectation of being instantly plunged into final misery." In this shocking condition he became the subject of medical care,

and he was placed in the receptacle for lunatics kept by Dr. Cotton of St. Alban's, an amiable and worthy physician, and the author of some well-known poems. At length he recovered a degree of serenity; but his mind had acquired that indelible tinge of melancholy by which it was ever after characterised, and which rendered his whole life little more than a succession of intervals of comfort between long paroxysms of settled despondency. It is unnecessary to follow him through all his scenes of retirement. Part of his time was spent at the house of his relation, Earl Cowper, at Cole-green; and part at Huntingdon, with his intimate friend the Reverend Mr. Unwin. After the death of the latter, he removed with his widow to Olney in Buckinghamshire, which was thenceforth the principal place of his residence. The affectionate intimacy he enjoyed with this lady is strongly expressed in the following lines, which have probably been understood by most readers as expressive of a conjugal union:

—Witness, dear companion of my walks,
Whose arm this twentieth winter I perceive
Fast lock'd in mine, with pleasure such as love
Confirm'd by long experience of thy worth
And well-tried virtues could alone inspire—
Witness a joy that thou hast doubled long.

TASK, B. I.

At Olney he contracted a close friendship with the Reverend Mr. Newton, then minister there, and since rector of St. Mary Woolnoth, London, whose religious opinions were in unison with his own. To a collection of hymns published by him, Mr. Cowper contributed a large number of his own composition. He first became known to the public in general as a poet by a volume printed in 1782. The pieces of which it consisted were of a singular cast; and if they did not at once place the writer high in the scale of poetic excellence, they sufficiently established his claim to originality, and gave tokens of a genius rather kept down by his subject than deficient in native power. The principal topics are, Error, Truth, Expulsion, Hope, Charity, Retirement, Conversation, all treated upon religious principles, and not without a considerable tinge of that rigour and austerity which belonged to his system. To this it must be attributed, that though naturally a man of kind affections, and more inclined to compassion than severity, yet, like the melancholy Jacques,

—most invectively he pierceth through
The body of the country, city, court.

These pieces are written in rhymed heroics, which he commonly manages with little grace or attention to melody. The style is rather strong and forcible than poetic; but though often prosaic, he is never flat or insipid; and sometimes the poet breaks through in a vein of lively description or bold figure. Of his talent for painting, a better specimen cannot be given than his draught of the melancholy man, probably sketched from what too faithful remembrance suggested of himself:

Look where he comes—In this embower'd alcove
Stand close concealed, and see a statue move;
Lips busy, and eyes fixt, foot falling slow,
Arms hanging idly down, hands claps'd below,
Interpret to the marking eye, distress,
Such as its symptoms only can express.
That tongue is silent now;—that silent tongue
Could argue once, could jest or join the song,
Could give advice, could censure or commend,
Or charm the sorrows of a drooping friend.
Renounce'd alike its office and its sport,
Its brisker and its graver strains fall short;

VOL. X.

Both fall beneath a fever's secret sway,
And like a summer brook are pass'd away.

RETIREMENT.

It does not appear that this volume excited much of the public notice; but his second volume, published in 1785, introduced his name to all the lovers of poetry, and raised him at least to an equality of reputation with any of his contemporaries. This chiefly consists of a poem in six books, entitled *The Task*, which name it derived from the injunction of a lady upon him to write a piece in blank verse, for the subject of which she gave him *the Sofa*. It sets out, indeed, with some sportive discussion of this topic, but it soon falls into a serious strain of rural description, intermixed with moral sentiments and portraits, which, under different titles, is preserved through the six books, with no perceptible method, but freely ranging from thought to thought, from the image to its improvement, as unthralled fancy suggests. It is difficult to determine which is the most conspicuous excellence of this charming production. In the description of natural objects, it unites the most minute accuracy with striking elegance and picturesque beauty. Since Thompson, Cowper is the poet who has added most to the stock of natural imagery; and his paintings are more exact than those of that writer, though generally less grand and comprehensive. His *manner*, indeed, has led some of his imitators into a kind of Dutch style of painting, which has wasted the powers of description upon objects not worth the pains; but Cowper himself is generally preserved by good taste from this degradation of his art. The pious and moral reflections of the *Task*, touch the heart with irresistible force; and its delineations of character are life itself. The personifications, and allegorical figures interspersed, display high powers of fancy; and the picture of Winter riding on his sledgy car, may vie in sublimity with any effort of poetical invention. The permanent colour of the diction is ease and force, sometimes deviating into negligence, but more free than perhaps any other blank verse from the stiffness and tumidity which so commonly disfigure this mode of writing. Although the peculiar religious system of the author is sufficiently discernible in the *Task*, it however appears with less gloom and austerity than in his former pieces. There is added to this volume *Tirocinium*, or a Review of Schools, a piece of great strength, and replete with striking observation, whatever he thought of the decisive sentence it pronounces against the public education of this country. The merry story of John Gilpin seems to shew (as indeed do many passages in his other works), that a strong perception of the ludicrous naturally balanced in his disposition the gloomy propensity which circumstances rendered finally predominant.

For the purpose of losing in employment those distressing ideas, which were ever apt to recur, he undertook the real *task* of translating into blank verse the whole of Homer's *Iliad* and *Odyssey*. This work possesses much merit of execution, and is certainly a much more exact representation of the ancient bard than Pope's ornamental version; but though the epic dignity is well supported in those passages which are intrinsically poetical, yet where the simplicity of the matter in the original is elevated into poetry solely by the force of sonorous versification, the poverty of English blank verse has scarcely been able to prevent it from sinking into mere prose. On the whole, this translation has probably been more praised than read; to the author, however, it was a most valuable source of innocent amusement, and its completion is mentioned by him with the regret felt on parting with a beloved companion.

Nothing, however, was capable of durably relieving his mind from the horrible impressions it had undergone; and

absolute despair was the state in which it finally settled. He passed some of his latter years under the affectionate care of a relation at East Dereham in Norfolk, nor did he entirely drop his literary employments, and the occasional composition of poems, till a short time before his death. This event took place, after a gradual decline of strength, on April 25th, 1800.—We are indebted to the popular biographical work of Dr. Aikin for the foregoing particulars.

COW-POX, a disease to which cows are subject, and from which mankind are likely to derive most important benefits.

In the summer of the year 1798, Dr. Jenner, of Berkeley in Gloucestershire, published several curious and interesting facts respecting this disease, which had been for a very long time known to the dairy farmers in the western counties of England. The most important of these is, that *persons who have once been affected with the cow-pox are thereby rendered incapable of variousious infection.*

"It appears (says Dr. Jenner) on the nipples of cows in the form of irregular pustules. At their first appearance they are commonly of a palish blue, or rather of a colour somewhat approaching to livid, and are surrounded by an erysipelatous inflammation. These pustules, unless a timely remedy be applied, frequently degenerate into phagedenic ulcers; the animals become indolent, and the secretion of milk is much lessened. Inflamed spots now begin to appear on different parts of the hands of the domestics employed in milking, and sometimes on the wrists, which quickly run on to suppuration, first assuming the appearance of small vesications produced by a burn. Most commonly they appear about the joints of the fingers, and at their extremities; but whatever parts are affected, if the situation will admit, these superficial suppurations put on a circular form with their edges more elevated than their centre, and of a colour distantly approaching to blue. Absorption takes place, and tumors appear in each axilla. The system becomes affected, the pulse is quickened, and shiverings with general lassitude and pains about the loins and limbs, with vomiting, come on. The head is painful, and the patient is now and then even affected with delirium. These symptoms, varying in their degree of violence, generally continue from one day to three or four, leaving ulcerated sores about the hands, which, from the sensibility of the parts, are very troublesome, and commonly heal slowly, frequently becoming phagedenic, like those from whence they spring."

There is not perhaps in the annals of medicine, to be found an example of experiment or enquiry, where the life and health of such numbers already born, and of all to be born, were implicated, that has been taken up more generally, received more candidly, or conducted more prudently, than this concerning the cow-pox. Some experiments, however, producing results which induced Dr. Jenner to apprehend that a *spurious* cow-pox had been communicated, he, in a subsequent work, laid down the following rules for the guidance of those who take the matter with which they inoculate *from the cow*.—He says, "The most perfect criterion by which the judgment may be guided is, perhaps, that adopted by those who attend infected cattle. These white blisters on the nipples, *say they, never eat into the fleshy parts*, like those which are commonly of a bluish cast, and which constitute the *true cow-pox*, but that they affect the skin only, quickly end in scabs, and are not nearly so infectious."

Dr. Woodville gives a tabular statement of the progressive descent of the cow-pox infection from patient to patient, as well as the magnitude of the disease which was excited by the inoculation. From the table, which extends much beyond our prescribed limits, we collect the following facts:

1. That out of about 500 cases of the inoculated cow-pox,

one proved fatal; and that in some others the disease, from the number of pustules, was of formidable severity; while, on the other hand, a very large proportion of the patients were scarcely disordered from the inoculation, and had no pustules.

2. That the matter of the vaccine disease has generally produced much fewer pustules and less indisposition than that of the small-pox.

3. That about two-fifths of all the persons inoculated for the variolæ vaccineæ had no pustules; and that in not more than a fourth part of them was there experienced any perceptible disorder of the constitution.

Dr. Pearson also engaged very extensively in this enquiry; and after various inferences drawn from experiments made by himself and communicated to others, he says:

"It now seems to me that the following facts are established on the foundation of experience:

- "1. A constitution which has undergone the small-pox is unsuceptible of again undergoing the disease.

- "2. A constitution which has not undergone the small-pox, but which has undergone the cow-pox, is unsuceptible of undergoing the small-pox.

- "3. A constitution which has not undergone the cow-pox, but which has undergone the small-pox, is unsuceptible of undergoing the cow-pox.

"Now, if the variolous poison destroys the susceptibility of the constitution to the future agency of this poison, in the respect of its producing the small-pox—and if the cow-pox poison destroys the susceptibility of the constitution to the future agency of the variolous poison, in the respect of its producing the small-pox—and if the variolous poison destroys the susceptibility of the constitution to the future agency of the vaccine poison, in the respect of its producing the cow-pox—it is demonstrated, that the same state of susceptibility of the constitution with respect to the future agency of the variolous poison, is produced equally by the agency of the variolous poison, and by the vaccine poison; but if the variolous poison produces unsuceptibility of the constitution to the future agency of the vaccine poison, it is demonstrable that the following fourth proposition is true, viz.

- "4. A constitution which has undergone the vaccine disease is unsuceptible of again undergoing that disease from the vaccine poison, because a state of unsuceptibility with respect to the agency of the variolous poison is produced by the vaccine poison (2d proposition), and a state of unsuceptibility with respect to the agency of the vaccine poison is produced by the variolous poison (3d proposition)—but the state of the constitution being the same in the two cases whether it be produced by the variolous or vaccine poison with respect to unsuceptibility, it seems inevitably in course, that unsuceptibility of the constitution to the future agency of the vaccine poison is produced by the vaccine disease; and the demonstration in course, could be given of the 1st proposition, on the ground of the 2d and 3d proposition, that unsuceptibility of the constitution to the agency of the variolous poison is produced by the variolous disease, if this were not already proved by abundant experience. "At a future time, however, I shall relate the observations and experiments to confirm this *a priori* conclusion; first, because these proofs will increase the validity of the 3d proposition; and secondly, because I do not mean to offer this demonstration as infallible, like mathematical."

It is by no means extraordinary that some accidents should occur to throw suspicion on the supposed efficacy attributed to the practice of inoculating the cow-pox; the preference due to it, however, over *variolous* inoculation, is rendered manifest by the following plain account of the matter given by Dr. Woodville in a periodical work. He says,

"In my report of the new inoculation, published in May

last, including upwards of 500 cases, I observed that the matter of the vaccine disease generally produced much fewer pustules, and less indisposition, than that of the small-pox. But at the same time it was remarked, that in some instances the cow-pox proved a very severe disease, and that one child died of spasmodic fits, occasioned by the eruptive fever which it excited. I hinted, however, that if the matter of the cow-pox used for the inoculations had been taken only from those patients in whom the disease appeared very mild and well characterised, the result would have been more favourable; and I have since had the satisfaction to find this opinion fully confirmed. For of 1000 persons inoculated for the vaccine disease, by me, or under my immediate direction, during the last six months, not more than 150 had pustules which proceeded to suppuration; nor was there one case attended with a dangerous symptom.

"Now, out of 1000 persons inoculated for the small-pox, I find generally that more than 800 have pustules; and as the severity of the disease is commonly in proportion to the number of the pustules, it follows that the cow-pox is milder than the inoculated small-pox in the proportion above mentioned.

"To infants at the breast the new inoculation has proved peculiarly successful, for I have now had a very considerable number of private patients of this description, in none of whom was the inoculation attended with any pustules, and even very rarely with any perceptible disorder of the constitution.

"That those who have undergone the vaccine disease, are thereby rendered secure against the effects of the small-pox, is a truth confirmed by daily experience. Upwards of 1000 of my patients, who had undergone the cow-pox, have been inoculated with variolous matter, yet none of them took the small-pox."

The SOCIETY for BETTERING the CONDITION of the POOR, desirous of extending this practice as much as possible, printed and distributed an Address to the Poor, which is introduced by these preliminary remarks:

"Notwithstanding the advantage of inoculation for the small-pox," say they, "it is a melancholy fact that the poor do still suffer very greatly by that disorder. The following address from the physicians, surgeons, and apothecaries, of the medical hospitals at Manchester, on the subject of inoculation for the cow-pox, may, it is hoped, have its effect in producing from our medical hospitals offers similar to that in the address, and also in preparing the minds of the poor to take the full benefit thereof. Two families near Manchester have lately inoculated for the cow-pox many hundreds of the neighbouring poor; who have all recovered without any sickness to confine them a single day. Twenty of them were afterwards inoculated for the small-pox; for a few days the usual signs of infection were perceived on the arms; but soon disappeared, without communicating the small-pox to any one of the twenty patients on whom this very satisfactory experiment was made."

Their ADDRESS to the POOR runs thus:

The experience of several years has fully proved, that inoculation for the cow-pox is a certain preservative against the small-pox; and is, besides, so mild and safe a disorder, when compared with the inoculated small-pox, that it has been generally introduced among the better informed, and more wealthy inhabitants, both of this kingdom and of various parts of Europe. In order, therefore, to impress strongly on the minds of the poor, the usefulness and superior advantages of this new plan of inoculation, the medical gentlemen (whose signatures are annexed) belonging to these charities, have thought it their duty to state, in this public manner, the following observations

for the serious perusal of all those poor persons, who feel a proper affection for their offspring, and who are desirous of promoting their own interest and comfort.

1. Inoculation for the cow-pox has been practised, for several years, with constant success, in various parts of this kingdom.

2. It has never failed to prevent the infection of the natural small-pox.

3. It may be communicated with safety to persons of every age and sex, and at all times and seasons of the year, with equal advantage.

4. The cow-pox is much preferable to the inoculated small-pox, as being a milder and safer disease, and not capable of infecting the persons living in the same family, or even sleeping in the same bed.

5. It does not produce eruptions, which scar and disfigure the face; and is seldom, if ever, attended with any other marks of the disease, than what appear on the arms from inoculation.

6. Neither swellings, blindness, lameness, nor any other complaints, which are known frequently to be the consequences of the natural small-pox (and sometimes, though but seldom, of the inoculated small-pox), have been observed to follow the cow-pox.

7. Alarming fits frequently seize children when sickening of the small-pox; and while cutting their teeth, this disorder often proves dangerous; but no such objections lie against the cow-pox.

8. So far from proving hurtful, delicate and sickly children are often improved in health by having passed through this complaint.

9. Scarcely any remedies or attendance are required for the cow-pox.

10. There is no necessity for a course of physic either before or after inoculation.

11. The time of the parents will not be taken up in attendance upon the sick, to the injury of the support of the rest of the family: and to poor families, this is an object of no small importance.

The prejudices of the poor against inoculation for the small-pox, by which thousands of lives have been annually saved, have been often lamented; but if they suffer unjust prejudices to prevent their laying hold of the advantages now offered to them, by the inoculation of the cow-pox, they will neglect the performance of a duty they owe to themselves, to their families, and to society at large.—For surely it is little less than criminal to expose their helpless children to the attack of so terrible and fatal a malady as the small-pox, when it may be readily avoided by the inoculation of so mild, simple, and safe a disease, as that of the cow-pox.

The great superiority of the inoculation of vaccine, in preference to variolous matter, consists in this:

That by the latter, infection is brought from all points of the compass; the seeds of a fatal disease are scattered over the whole face of the kingdom; and where a single life is preserved by variolous inoculation, several perhaps are lost by the accidental communication of the natural disease through the neighbourhood. On the other hand, the cow-pox, besides being more free from danger to the patient, confers its benefits to individuals without endangering the community, and without the possibility of extending it to any person in the same family.

COX (Richard) (*Encycl.*). This zealous reformer we find had not totally lost sight of the popish text, *compel them to come in*. A strong proof of his implacability and self-importance appears in his letter to the lord-treasurer Burleigh, in which he warmly expostulates with the council for inter-

posing in behalf of the Puritans, or meddling in affairs of the church, admonishing them to keep their own sphere. Such language from a bishop would make a modern privy-council stare. His works are, 1. Two Latin Orations on the Dispute between Dr. Tresham and Peter Martyr, Lond. 1549, 4to. 2. Liturgy of the Church of England; in compiling, and afterwards correcting which, he was principally concerned. 3. The Lord's Prayer in verse, commonly printed at the end of David's Psalms, by Sternhold and Hopkins. 4. Translation of the Four Gospels, the Acts of the Apostles, and the Epistle to the Romans, in the new translation of the Bible in the reign of Queen Elizabeth. 5. Resolutions of some Questions concerning the Sacrament, in the Collection of Records at the end of Burnet's History of the Reformation. 6. Several Letters to the Queen and others, published in Strype's Annals of the Reformation. He is also said to have been concerned in the declaration concerning the divine institution of bishops, and to have assisted Lile in his grammar.

CRACKER, or **SEA-PHEASANT**, in ornithology, the English name of the *anacausa*. See **ANAS**.

CRAIGMILLAR, a ruinous castle, 2 miles S.E. of Edinburgh, in which Mary queen of Scots resided, after her return from Paris in 1562. Her French retinue were lodged in an adjacent village, thence called Little France; and here too, repenting her rash match with the profligate Lord Darneley, she often retired, to indulge her melancholy in solitude.

CRAINBURG, a town of Germany, in Carniola, on the river Saave, 20 miles N.W. of Laubach. Long. 14. 5. E. Lat. 46. 36. N.

CRAMBE (*Encycl.*), erroneously spelt **CRAMBLE**.

CRAMMOND WATER, a river of Edinburghshire, in Scotland, called also the Almond. For several miles it divides this county from Linlithgowshire, and falls into the Frith of Forth, at the small village of Crammond, a place remarkable for the traces of a great Roman station. Its fertile banks are adorned with villages and country seats.

CRANBOURN, a town of Dorsetshire, with a market on Wednesday. It is well watered with streams, and has a fine chafe, which extends almost to Salisbury. It is 38 miles N.E. of Dorchester, and 94 W. of London.

CRANBROOK, a large town in Kent, with a market on Saturday, the best in these parts. It is 13 miles S. of Maidstone, and 52 S.E. of London. Long. o. 39. E. Lat. 51. 4. N.

CRANE (*Encycl.*). In that article, the descriptions of the figures in Plate 88, Vol. II. have been accidentally omitted. The following is a description of Mr. White's crane.

A, a circular-inclined plane, moving on a pivot underneath it, and carrying round with it the axis E. A person walking on this plane and pressing against the lever B, throws off the gripe D by means of an iron rod C, and thus admits the plane and its axis to move freely, and raise the weight G by the coiling of the rope F round the axis E. To show more clearly the construction and action of the lever and gripe, a plan of a circular-inclined plane with the lever and gripe is added, where B represents the lever, D the spring or gripe. In this plan, when the lever B is in the situation it now appears, the spring or gripe D presses against the periphery of the plane, as shewn by the double line; and the machine cannot move but when the lever B is pressed out to the dotted line H; the gripe is also thrown off to the dotted line I, and the whole machine left at liberty to move. One end of a rope or cord, of a proper length, is fixed near the end of the lever B, and the other end made fast to one of the uprights,

serving to prevent the lever moving too far when pressed by the man.

The *improved crane*, represented in the same plate, consists simply in introducing the action of a worm, that communicates the first motion to the crane, upon the axis of the wheel in which the man walks. The axis of this wheel, and that of the worm, are proposed to be in separate parts, and occasionally united by a coupling-box. When goods are to be raised, the two axes should be connected; when lowered, they may be disunited, and the worm turned by a winch. Thus, the ascent, or descent, of the weight may be accelerated, or stopped at pleasure, by the person walking on the axis of the wheel, or turning the winch; without the remotest possibility of being overpowered by the descending weight.

Explanation of the figure in the plate. A, the wheel in which the man walks. B, the coupling-box. C, the worm. D, the wheel in which it works. E, a wheel upon the same axis, giving motion to F. F, a wheel upon the axis of the windlass. G, the winch.

This machinery may be applied to a crane already erected upon the common principle. The inventor proposes to put a wheel on any convenient axis in the machine, in its present state; and, on this, a worm that may be thrown in or out of gear at pleasure; and to let the lever, by which it is effected, lie within the reach of the man's hand in the wheel. The goods being fastened to the crane, and raised from the floor of the warehouse, in order to be let down, the man puts the worm into the gear, leaves the wheel, and causes them to descend by the winch.

In the same plate (88. Vol. II.) is given a representation of an excellent contrivance for preventing the shocking accidents which occasionally happen to the men who work wheel cranes. This is caused by the weight of the goods they are attempting to raise, being too considerable for the power that is opposed to it; consequently the wheel runs back with great velocity, and unless the useful appendage here spoken of, form a part of the construction, the persons within it are dashed to pieces.

In the view of this contrivance, AA is the axle of the crane; BB two circular pieces, on which are affixed, at convenient distances, several pulleys, carrying, by means of a rope, two bows of iron CC, on which rests a wooden holder D; by this last the men can suspend themselves if the wheel should accidentally revolve, so as to avoid injury.

These contrivances are alike eminent for their ingenuity; but we can by no means omit noticing a kind of crane invented by Mr. Abraham Andrews, of Higham Ferrers, Northamptonshire. This machine weighs the body suspended, while it is raising; an improvement for which the Society for the Encouragement of Arts, &c. in 1791, granted him a premium of 15 guineas.

The proportion of the beam in the plate is as 1 to 20, the large weight being 5 pounds, and the smaller $\frac{1}{4}$ of a pound. The latter, when fixed on the beam-end, will equipoise the former, if hung on the pulley at the end of the gib-beam, which should be placed in a right line with the crane, at the time the weight is adjusted; otherwise it will occasion a friction that may prevent the moveable beam from playing freely.

The following is a description of Mr. A. Andrews's weighing-crane, represented in Plate 24 of this supplement.

The gib of the crane stands on a horizontal beam, moveable on a centre, at A: and the distance of the centre A, from the bearing of the upright, being to the distance B, in the proportion of 1 to 20, the weight placed at B, de-

termines that of the body suspended in the same proportion. C is a stub, or piece of wood, which projects from the weight hanging at the end of the gib, and serves to prevent the beam from rising to too great a height.

CRANGANORE, a town and fort of the peninsula of Hindoostan, on the coast of Malabar, lately subject to the Dutch, by whom it was taken from the Portuguese in 1662. In 1789, the Dutch sold this place to the rajah of Travancore. But Tippoo Sultan, regent of Mysore, disputing their right to sell it, a war ensued between that prince and the rajah, who being powerfully supported by the English and their allies, the nizam of the Deccan and the Maharattas, the war was happily terminated in 1792; Tippoo consenting to pay above three crores of rupees towards the expenses of the war, and to cede one-half of his dominions to the three confederate powers. Cranganore is seated at the mouth of a river, 24 miles N. by W. of Cochin. Long. 76. 30. E. Lat. 10. 23. N.

CREA (*Encycl.*), placed erroneously after the article CREUSA.

CREETOWN, a small port of Scotland, on the E. side of Wigton Bay, in Kirkcudbrightshire. Here several loops are constantly employed in carrying sea-shells coalwise, or importing coal and lime from Cumberland. The shells are dug from banks without the sea-mark, and are esteemed a valuable manure.

CREIFF, a town of Scotland, in Perthshire. Its annual fair for cattle is one of the greatest in Scotland. It is seated on the river Earn, 20 miles W. of Perth.

CREIL, a town of France, in the department of Oise, and late province of the Isle of France. It is seated on the Oise, five miles from Senlis. Long. 2. 43. E. Lat. 49. 13. N.

CREMIU, a small town of France, in the department of Here, and late province of Dauphiny, at the foot of a mountain, a mile from the Rhone. Long. 5. 20. E. Lat. 45. 44. N.

CREMNITZ, the principal mine-town of Upper Hungary, 70 miles N.E. of Presburg. Long. 19. 6. E. Lat. 48. 32. N.

CREMONA, a city of Italy, and capital of a district of the Milanese, called from it the *Cremonese*; is situated 45 miles south-east of Milan, in E. Long. 10. 30. and N. Lat. 45. 0.

CREMONESE, a territory of Italy, in the duchy of Milan, bounded on the E. by Mantua, on the N. by Bresciano, on the W. by Cremafco and Lodez-Lodezan, and on the S. by Parma. It is fertile in wine and fruits, and belongs to the house of Austria. Cremona is the capital.

CREMPEN, a town of Germany, in the duchy of Holstein, five miles from Hamburg.

CRESCENTINO, a town of Piedmont, on the river Po. It was taken by the French in 1704, and by the allies in 1706. It is 20 miles N.E. of Turin. Long. 8. 0. E. Lat. 45. 20. N.

CRESPY, a town of France, in the department of Oise, and late province of the Isle of France, 17 miles S. of Compiègne. Long. 2. 55. E. Lat. 49. 10. N.

CREVECEUR, a town of France, in the department of the North, and late province of Cambrésis, seated on the Scheld, five miles S. of Cambray. Long. 3. 20. E. Lat. 50. 6. N.

CREUSE, a department of France, so named from a river that falls into the Vienne, and containing the late province of Marche. Gueret is the capital.

CREUTZNACH, a town of Germany, in the palatinate of the Rhine, with a castle on an eminence. It is 20 miles S.W. of Mentz. Long. 7. 55. E. Lat. 49. 44. N.

CREWKERNE, a town of Somersetshire, with a market on Saturday. It is seated on a branch of the Parret. Three miles beyond this town is a hill that commands one of the most beautiful prospects in the kingdom. Crewkerne is 132 miles W. by S. of London. Long. 3. 0. W. Lat. 50. 50. N.

CREX, in ornithology (*Encycl.*), a species of RALLUS, erroneously spelt CREA.

CRICKHOWEL, a town of Brecknockshire, with a market on Thursday. It is seated on the river Ufk, 10 miles E. by S. of Brecknock. Long. 3. 7. W. Lat. 51. 49. N.

CRIMES AND PUNISHMENTS (*Encycl.*). Although we have already been somewhat particular in what is communicated under this head, we nevertheless, are so far aware of the importance of the subject to every individual, as to have determined to add, in this place, some account of the general nature of crimes, in which we shall chiefly follow Judge Blackstone.

1. A crime, or misdemeanour, is an act committed, or omitted, in violation of a public law, either forbidding or commanding it. This general definition comprehends both crimes and misdemeanours; which, properly speaking, are mere synonymous terms: though, in common usage, the word "crimes" is made to denote such offences as are of a deeper and more atrocious dye; while smaller faults, and omissions of less consequence, are comprised under the gentler name of "misdemeanours" only.

The distinction of public wrongs from private, of crimes and misdemeanours from civil injuries, seems principally to consist in this: that private wrongs, or civil injuries, are an infringement or privation of the civil rights which belong to individuals, considered merely as individuals; public wrongs, or crimes and misdemeanours, are a breach and violation of the public rights and duties, due to the whole community, considered as a community, in its social aggregate capacity. As if I detain a field from another man, to which the law has given him a right, this is a civil injury, and not a crime; for here only the right of an individual is concerned, and it is immaterial to the public which of us is in possession of the land: but treason, murder, and robbery, are properly ranked among crimes; since, besides the injury done to individuals, they strike at the very being of society; which cannot subsist where actions of this sort are suffered to escape with impunity.

In all cases the crime includes an injury: every public offence is also a private wrong, and somewhat more; it affects the individual, and it likewise affects the community. Thus treason in imagining the king's death, involves in it conspiracy against an individual, which is also a civil injury: but as this species of treason in its consequences principally tends to the dissolution of government, and the destruction thereby of the order and peace of society, this denominates it a crime of the highest magnitude. Murder is an injury to the life of an individual; but the law of society considers principally the loss which the state sustains by being deprived of a member, and the pernicious example thereby set, for others to do the like. Robbery may be considered in the same view: it is an injury to private property; but, were that all, a civil satisfaction in damages might atone for it: the public mischief is the thing, for the prevention of which our laws have made it a capital offence. In these gross and atrocious injuries the private wrong is swallowed up in the public: we seldom hear any mention made of satisfaction to the individual; the satisfaction to the community being so very great. And indeed, as the public crime is not otherwise avenged than by forfeiture of

life and property, it is impossible afterwards to make any reparation for the private wrong; which can only be had from the body or goods of the aggressor. But there are crimes of an inferior nature, in which the public punishment is not so severe, but it affords room for a private compensation also: and herein the distinction of crimes from civil injuries is very apparent. For instance; in the case of battery, or beating another, the aggressor may be indicted for this at the suit of the king, for disturbing the public peace, and be punished criminally by fine and imprisonment: and the party beaten may also have his private remedy by action of trespass for the injury, which he in particular sustains, and recover a civil satisfaction in damages. So also, in case of a public nuisance, as digging a ditch across a highway, this is punishable by indictment, as a common offence to the whole kingdom, and all his majesty's subjects: but if any individual sustains any special damage thereby, as laming his horse, breaking his carriage, or the like, the offender may be compelled to make ample satisfaction, as well for the private injury, as for the public wrong.

II. The nature of crimes and misdemeanours in general being thus ascertained and distinguished, we proceed, in the next place, to consider the general nature of punishments: which are evils or inconveniences consequent upon crimes and misdemeanours; being devised, denounced, and inflicted by human laws, in consequence of disobedience or misbehaviour in those, to regulate whose conduct such laws were respectively made. And herein we will briefly consider the power, the end, and the measure, of human punishment.

1. As to the power of human punishment, or the right of the temporal legislator to inflict discretionary penalties for crimes and misdemeanours. It is clear, that the right of punishing crimes against the law of nature, as murder and the like, is in a state of mere nature vested in every individual. For it must be vested in somebody; otherwise the laws of nature would be vain and fruitless, if none were empowered to put them in execution: and if that power is vested in any one, it must also be vested in all mankind; since all are by nature equal. Whereof the first murderer Cain was so sensible, that we find him expressing his apprehensions, that whoever should find him would slay him. In a state of society this right is transferred from individuals to the sovereign power; whereby men are prevented from being judges in their own causes, which is one of the evils that civil government was intended to remedy. Whatever power therefore individuals had of punishing offences against the law of nature, that is now vested in the magistrate alone; who bears the sword of justice by the consent of the whole community. And to this precedent natural power of individuals must be referred that right, which some have argued to belong to every state (though, in fact, never exercised by any), of punishing not only their own subjects, but also foreign ambassadors, even with death itself; in case they have offended, not indeed against the municipal laws of the country, but against the divine laws of nature, and become liable thereby to forfeit their lives for their guilt.

As to offences merely against the laws of society, which are only *mala prohibita*, and not *mala in se*; the temporal magistrate is also empowered to inflict coercive penalties for such transgression: and this by the consent of individuals; who, in forming societies, did, either tacitly or expressly, invest the sovereign power with a right of making laws, and of enforcing obedience to them when made, by exercising, upon their non-observance, severities adequate to the evil. The lawfulness therefore of punishing such criminals is founded upon this principle, that the

law by which they suffer was made by their own consent; it is a part of the original contract into which they entered, when first they engaged in society; it was calculated for, and has long contributed to, their own security.

This right therefore, being thus conferred by universal consent, gives to the state exactly the same power, and no more, over all its members, as each individual member had naturally over himself or others. Which has occasioned some to doubt, how far a human legislature ought to inflict capital punishments for positive offences; offences against the municipal law only, and not against the law of nature; since no individual has, naturally, a power of inflicting death upon himself or others for actions in themselves indifferent. With regard to offences *mala in se*, capital punishments are in some instances inflicted by the immediate command of God himself to all mankind; as, in the case of murder, by the precept delivered to Noah, their common ancestor and representative, "Whoso sheddeth man's blood, by man shall his blood be shed." In other instances they are inflicted after the example of the Creator, in his positive code of laws for the regulation of the Jewish republic; as in the case of the crime against nature. But they are sometimes inflicted without such express warrant or example, at the will and discretion of the human legislature; as for forgery, for theft, and sometimes for offences of a lighter kind. This practice is thus justified by that great and good man, Sir Matthew Hale: "When offences grow enormous, frequent, and dangerous to a kingdom or state, destructive or highly pernicious to civil societies, and to the great insecurity and danger of the kingdom or its inhabitants, severe punishment and even death itself is necessary to be annexed to laws in many cases by the prudence of lawgivers." It is therefore the enormity, or dangerous tendency, of the crime, that alone can warrant any earthly legislature in putting him to death that commits it. It is not its frequency only, or the difficulty of otherwise preventing it, that will excuse our attempting to prevent it by a wanton effusion of human blood. For, though the end of punishment is to deter men from offending, it never can follow from thence, that it is lawful to deter them at any rate and by any means; since there may be unlawful methods of enforcing obedience even to the justest laws. Every human legislator will be therefore extremely cautious of establishing laws that inflict the penalty of death, especially for slight offences, or such as are merely positive. He will expect a better reason for his so doing, than that loose one which generally is given; that it is found by former experience that no lighter penalty will be effectual. For it is found upon further experience, that capital punishments are more effectual. Was the vast territory of all the Russias worse regulated under the Empress Elizabeth, than under her more sanguinary predecessors? Was it under Catherine II. less civilized, less social, less secure? And yet we are assured, that neither of these illustrious princesses have, throughout their whole administration, inflicted the penalty of death: and the latter, upon full persuasion of its being useless, nay even pernicious, gave orders for abolishing it entirely throughout her extensive dominions. But indeed, were capital punishments proved by experience to be a sure and effectual remedy, that would not prove the necessity (upon which the justice and propriety depend) of inflicting them upon all occasions when other expedients fail. It is feared this reasoning would extend a great deal too far. For instance, the damage done to our public roads by loaded waggons is universally allowed, and many laws have been made to prevent it, none of which have hitherto proved effectual. But it does not therefore follow, that it would be

just for the legislature to inflict death upon every obstinate carrier, who defeats or eludes the provisions of former statutes. Where the evil to be prevented is not adequate to the violence of the preventive, a sovereign that thinks seriously can never justify such a law to the dictates of conscience and humanity. To shed the blood of our fellow-creature is a matter that requires the greatest deliberation, and the fullest conviction of our own authority: for life is the immediate gift of God to man; which neither he can resign, nor can it be taken from him, unless by the command or permission of him who gave it, either expressly revealed, or collected from the laws of nature or society by clear and indisputable demonstration.

We would not be understood to deny the right of the legislature in any country to enforce its own laws by the death of the transgressor, though persons of some abilities have doubted it; but only to suggest a few hints for the consideration of such as are, or may hereafter, become legislators. When a question arises, whether death may be lawfully inflicted for this or that transgression, the wisdom of the laws must decide it: and to this public judgment or decision all private judgments must submit; else there is an end of the first principle of all society and government. The guilt of blood, if any, must lie at their doors, who misinterpret the extent of their warrant; and not at the doors of the subject, who is bound to receive the interpretations that are given by the sovereign power.

2. As to the end, or final cause, of human punishments. This is not by way of atonement or expiation for the crime committed; for that must be left to the just determination of the Supreme Being: but as a precaution against future offences of the same kind. This is effected three ways: either by the amendment of the offender himself; for which purpose all corporal punishments, fines, and temporary exile or imprisonment, are inflicted: or, by deterring others by the dread of his example from offending in the like way, "*ut parricidæ* (as Tully expresses it) *ad paucos, metus ad omnes, perveniat*," which gives rise to all ignominious punishments, and to such executions of justice as are open and public: or, lastly, by depriving the party injuring of the power to do future mischief; which is effected by either putting him to death, or condemning him to perpetual confinement, slavery, or exile. The same end, of preventing future crimes, is endeavoured to be answered by each of these three species of punishment. The public gains equal security, whether the offender himself be amended by wholesome correction, or whether he be disabled from doing any further harm: and, if the penalty fails of both these effects, as it may do, still the terror of his example remains as a warning to other citizens. The method however of inflicting punishment ought always to be proportioned to the particular purpose it is meant to serve, and by no means to exceed it; therefore the pains of death, and perpetual disability by exile, slavery, or imprisonment, ought never to be inflicted but when the offender appears incorrigible: which may be collected either from a repetition of minor offences; or from the perpetration of some one crime of deep malignity, which of itself demonstrates a disposition without hope or probability of amendment: and in such cases it would be cruelty to the public to defer the punishment of such a criminal till he had an opportunity of repeating perhaps the worst of villainies.

3. As to the measure of human punishments. From what has been observed in the former articles we may collect, that the quantity of punishment can never be absolutely determined by any standing invariable rule; but it must be left to the arbitration of the legislature to inflict such penalties as are warranted by the laws of nature and society, and such as ap-

pear to be the best calculated to answer the end of precaution against future offences.

Hence it will be evident, that what some have so highly extolled for its equity, the *lex talionis*, or "law of retaliation," can never be in all cases an adequate or permanent rule of punishment. In some cases indeed it seems to be dictated by natural reason; as in the case of conspiracies to do an injury, or false accusations of the innocent; to which we may add that law of the Jews and Egyptians, mentioned by Josephus and Diodorus Siculus, that whoever, without sufficient cause, was found with any mortal poison in his custody, should himself be obliged to take it. But, in general, the difference of persons, place, time, provocation, or other circumstances, may enhance or mitigate the offence; and in such cases retaliation can never be a proper measure of justice. If a nobleman strikes a peasant, all mankind will see, that if a court of justice awards a return of the blow, it is more than a just compensation. On the other hand, retaliation may sometimes be too easy a sentence; as, if a man maliciously should put out the remaining eye of him who had lost one before it, it is too slight a punishment for the maimer to lose only one of his: and therefore the law of the Locrians, which demanded an eye for an eye, was in this instance judiciously altered; by decreasing, in imitation of Solon's laws, that he who struck out the eye of a one-eyed man, should lose both his own in return. Besides, there are very many crimes, that will in no shape admit of these penalties, without manifest absurdity and wickedness. Theft cannot be punished by theft, defamation by defamation, forgery by forgery, adultery by adultery, and the like. And we may add, that those instances, wherein retaliation appears to be used, even by the divine authority, do not really proceed upon the rule of exact retribution, by doing to the criminal the same hurt he has done to his neighbour, and no more: but this correspondence between the crime and punishment is barely a consequence from some other principle. Death is ordered to be punished with death; not because one is equivalent to the other, for that would be expiation, and not punishment. Nor is death always an equivalent for death: the execution of a needy decrepid assassin is a poor satisfaction for the death of a nobleman in the bloom of his youth, and full enjoyment of his friends, his honours, and his fortune. But the reason upon which this sentence is grounded seems to be, that this is the highest penalty that man can inflict, and tends most to the security of the world; by removing one murderer from the earth, and setting a dreadful example to deter others: so that even this grand instance proceeds upon other principles than those of retaliation. And truly, if any measure of punishment is to be taken from the damage sustained by the sufferer, the punishment ought rather to exceed than equal the injury: since it seems contrary to reason and equity, that the guilty (if convicted) should suffer no more than the innocent has done before him; especially as the suffering of the innocent is past and irrevocable, that of the guilty is future, contingent, and liable to be escaped or evaded. With regard indeed to crimes that are incomplete, which consist merely in the intention, and are not yet carried into act, as conspiracies and the like; the innocent has a chance to frustrate or avoid the villainy, as the conspirator has also a chance to escape his punishment: and this may be one reason why the *lex talionis* is more proper to be inflicted, if at all, for crimes that consist in intention, than for such as are carried into act. It seems indeed consonant to natural reason, and has therefore been adopted as a maxim by several theoretical writers, that the punishment due to the crime of which one falsely accuses another, should be inflicted on the perjured informer. Accordingly, when it was once attempted to introduce into

England the law of retaliation, it was intended as a punishment for such only as preferred malicious accusations against others; it being enacted by statute 37 Edw. III. c. 18. that such as preferred any suggestions to the king's great council should put in forfeitures of tallies; that is, to incur the same pain that the other should have had, in case the suggestion were found untrue. But, after one year's experience, this punishment of tallies was rejected, and imprisonment adopted in its stead.

But though from what has been said it appears, that there cannot be any regular determinate method of rating the quantity of punishments for crimes, by any one uniform rule; but they must be referred to the will and discretion of the legislative power: yet there are some general principles, drawn from the nature and circumstances of the crime, that may be of some assistance in allotting it an adequate punishment.

As, first, with regard to the object of it: for the greater and more exalted the object of an injury is, the more care should be taken to prevent that injury, and of course under this aggravation the punishment should be more severe. Therefore treason in conspiring the king's death is (in Britain) punished with greater rigour than even actually killing any private subject. And yet, generally, a design to transgress is not so flagrant an enormity, as the actual completion of that design. For evil, the nearer we approach it, is the more disagreeable and shocking: so that it requires more obliquity in wickedness to perpetrate an unlawful action, than barely to entertain the thought of it: and it is an encouragement to repentance and remorse, even till the last stage of any crime, that it never is too late to retract; and that if a man stops even here, it is better for him than if he proceeds: for which reasons an attempt to rob, to ravish, or to kill, is far less penal than the actual robbery, rape, or murder. But in the case of a treasonable conspiracy, the object whereof is the king's majesty, the bare intention will deserve the highest degree of severity: not because the intention is equivalent to the act itself, but because the greatest rigour is no more than adequate to a treasonable purpose of the heart, and there is no greater left to inflict upon the actual execution itself.

Again: The violence of passion, or temptation, may sometimes alleviate a crime; as theft, in case of hunger, is far more worthy of compassion, than when committed through avarice, or to supply one in luxurious excesses. To kill a man upon sudden and violent resentment is less penal than upon cool deliberate malice. The age, education, and character, of the offender; the repetition (or otherwise) of the offence; the time, the place, the company wherein it was committed; all these, and a thousand other incidents, may aggravate or extenuate the crime*.

Further: As punishments are chiefly intended for the prevention of future crimes, it is but reasonable that among crimes of different natures those should be most severely punished, which are the most destructive of the public safety and happiness; and, among crimes of an equal malignity, those which a man has the most frequent and easy opportunities of committing, which cannot be so easily guarded against as others, and which therefore the offender has the strongest inducement to commit: according to what Cicero observes, "*ea sunt animadvertenda peccata maxime, quæ difficillime præcavetur*." Hence it is, that for a servant to rob his master is in more cases capital; than for a stranger: if a servant kills his master, it is a species of treason; in another it is only murder: to steal a handkerchief, or other trifle of above the

value of twelve pence, privately from one's person, is made capital; but to carry off a load of corn from an open field, though of fifty times greater value, is punished with transportation only. And, in the island of Man, this rule was formerly carried so far, that to take away a horse or an ox was there no felony, but a trespass, because of the difficulty in that little territory to conceal them or carry them off: but to steal a pig or a fowl, which is easily done, was a capital misdemeanour, and the offender was punished with death.

Lastly, as a conclusion to the whole, we may observe, that punishments of unreasonable severity, especially when indiscriminately inflicted, have less effect in preventing crimes, and amending the manners of a people, than such as are more merciful in general, yet properly intermixed with due distinctions of severity. It is the sentiment of an ingenious writer, who seems to have well studied the springs of human action, that crimes are more effectually prevented by the certainty, than by the severity, of punishment. For the excessive severity of laws (says Montesquieu) hinders their execution: when the punishment surpasses all measure, the public will frequently out of humanity prefer impunity to it. Thus also the statute 1 Mar. II. c. 1. recites in its preamble, "that the state of every king confits more assuredly in the love of the subject towards their prince, than in the dread of laws made with rigorous pains; and that laws made for the preservation of the commonwealth without great penalties are more often obeyed and kept, than laws made with extreme punishments." Happy had it been for the nation, if the subsequent practice of that deluded prince in matters of religion, had been correspondent to these sentiments of herself and parliament, in matters of state and government! We may further observe, that sanguinary laws are a bad symptom of the dis temper of any state, or at least of its weak constitution. The laws of the Roman kings, and the twelve tables of the *decemviri*, were full of cruel punishments: the Porcian law, which exempted all citizens from sentence of death, silently abrogated them all. In this period the republic flourished: under the emperors severe punishments were revived; and then the empire fell.

It is moreover absurd and impolitic to apply the same punishment to crimes of different malignity. A multitude of sanguinary laws (besides the doubt that may be entertained concerning the right of making them) do likewise prove a manifest defect either in the wisdom of the legislative, or the strength of the executive, power. It is a kind of quackery in government, and argues a want of solid skill, to apply the same universal remedy, the *ultimum supplicium*, to every case of difficulty. It is, it must be owned, much easier to extirpate than to amend mankind; yet that magistrate must be esteemed both a weak and a cruel surgeon, who cuts off every limb, which through ignorance or indolence he will not attempt to cure. It has been therefore ingeniously proposed, that in every state a scale of crimes should be formed, with a corresponding scale of punishments, descending from the greatest to the least: but, if that be too romantic an idea, yet at least a wise legislator will mark the principal divisions, and not assign penalties of the first degree to offences of an inferior rank. Where men see no distinction made in the nature and gradations of punishment, the generality will be led to conclude there is no distinction in the guilt. Thus in France the punishment of robbery, either with or without murder, was the same: hence it was, that though perhaps they were therefore subject to fewer robberies, yet they never robbed but they also

* Thus Demosthenes (in his oration against Midias) finely works up the aggravations of the insults he had received. "I was abused (says he) by my enemy, in cold blood, out of malice, not by heat of wine, in the morning, publicly, before strangers as well as citizens; and that in the temple, whither the duty of my office called me."

murdered. In China murderers are cut to pieces, and robbers not : hence in that country they never murder on the highway, though they often rob. And in Britain, besides the additional terrors of a speedy execution, and a subsequent exposure or dissection, robbers have a hope of transportation, which seldom is extended to murderers. This has the same effect here as in China, in preventing frequent assassination and slaughter.

Persons capable, or incapable, of committing CRIMES ; or (which is all one) of suffering the censures of the law upon the commission of forbidden acts.

All the several pleas and excuses, which protect the committer of a forbidden act from the punishment which is otherwise annexed thereto, may be reduced to this single consideration, the want or defect of *will*. An involuntary act, as it has no claim to merit, so neither can it induce any guilt : the concurrence of the will, when it has its choice either to do or to avoid the fact in question, being the only thing that renders human actions either praise-worthy or culpable. Indeed, to make a complete crime, cognizable by human laws, there must be both a will and an act. For though, *in foro conscientiae*, a fixed design or will to do an unlawful act is almost as heinous as the commission of it ; yet, as no temporal tribunal can search the heart, or fathom the intentions of the mind, otherwise than as they are demonstrated by outward actions, it therefore cannot punish for what it cannot know. For which reason, in all temporal jurisdictions, an *overt act*, or some open evidence of an intended crime, is necessary, in order to demonstrate the depravity of the will, before the man is liable to punishment. And as a vicious will without a vicious act is no civil crime, so, on the other hand, an unwarrantable act without a vicious will is no crime at all. So that to constitute a crime against human laws, there must be, first, a vicious will ; and, secondly, an unlawful act consequent upon such vicious will.

Now there are three cases, in which the will does not join with the act : 1. When there is a defect of understanding. For where there is no discernment, there is no choice ; and where there is no choice, there can be no act of the will, which is nothing else but a determination of one's choice to do or to abstain from a particular action : he, therefore, that has no understanding, can have no will to guide his conduct. 2. Where there is understanding and will sufficient, residing in the party ; but not called forth and exerted at the time of the action done ; which is the case of all offences committed by chance or ignorance. Here the will sits neuter ; and neither concurs with the act, nor disagrees to it. 3. Where the action is constrained by some outward force and violence. Here the will counteracts the deed ; and is so far from concurring with, that it loaths and disagrees to, what the man is obliged to perform. Infancy, idiocy, lunacy, and intoxication, fall under the first class ; misfortune and ignorance may be referred to the second ; and compulsion or necessity may properly rank in the third. See INFANCY, IDIOCY, DRUNKENNESS, MISFORTUNE, IGNORANCE, NECESSITY.

CROIA, a town of Albania, in Turkey in Europe, with a bishop's see. It is seated near the gulf of Venice, 13 miles N. E. of Durazzo. Long. 19. 27. E. Lat. 42. 6. N.

CROMACK-WATER, a lake of Cumberland, between Buttermere and Lowelwater, with each of which it is connected by the river Cocker. It is four miles long, and, in some places, near half a mile over. It is beautified with three small isles, one of them a rock. At the N. E. corner is a handsome stone bridge of four arches over its outlet, the Cocker. The water of this lake, though clear, is not so transparent as the lake of Derwent ; but, as well as Buttermere and Lowelwater, it is of a much greater depth than the Derwent. It abounds with very fine char and red trout.

VOL. X.

CROMARTY, a county of Scotland, which comprehends part of a peninsula on the fourth side of the Frith, to which it gives name. On the S. and W. it is bounded by Ross-shire. It is 12 miles long from E. to W. and about three in its greatest breadth. It is fertile and well cultivated ; but it is now almost destitute of old trees ; though, in the days of James V. it was a forest, and afforded shelter to many wolves. It sends one member to parliament, alternately with Nairne.

CROMER, a small town of Norfolk, with a market on Saturday. It is seated near the sea, and was formerly more considerable than at present ; for it had two churches, one of which, with several houses, was swallowed up by the sea. The inhabitants are now chiefly fishermen. The part of a church, which still remains, was built in the time of the Saxons, of curious flint, and the tower was raised to a great height : this, indeed, is all that stands, and the other part of this structure being decayed, divine service is performed once a fortnight in the steeple. It is 22 miles N. of Norwich, and 127 N. E. of London. Long. 1. 15. W. Lat. 53. 0. N.

CROMFORD, a village in Derbyshire, on the river Derwent, in the road from Derby to Manchester. Here Mr. (afterwards Sir Richard) Arkwright erected some of the new cotton mills, a capital improvement of mechanism due to him ; and by means of which the various branches of the cotton manufacture have wonderfully spread in this and the adjacent countries. Here also Sir Richard Arkwright built, before his death, a noble seat, and a church. Cromford is 14 miles N. N. W. of Derby.

CROMWELL (Richard), eldest son of Oliver Cromwell, was by his father appointed successor to the protectorship, but very soon deposed by the army. They discharged his debts, took all the household stuff, plate, &c. gave him a protection for six months, and so he retired. He was by no means qualified to support the station gained by the aspiring talents of his father ; he was of a moderate temper, and untainted with that fanatical spirit which his father had so successfully cultivated : on the restoration he went abroad ; but returned in 1680 under the assumed name of Clark, and settled at Cheshunt, in Hertfordshire, where he lived privately, and died in 1712, aged 86.

CRONACH, a town of Germany, in the circle of Franconia, and bishopric of Bamberg, with a citadel. It is 25 miles N. E. of Bamberg. Long. 11. 35. E. Lat. 50. 27. N.

CRONBORG, a fortress of Denmark, on the isle of Zealand, near Elsinore, which guards the passage of the Sound. In this fortress is a royal palace, in which the late unfortunate and much-injured queen Matilda was imprisoned till she was permitted to retire to Zell. About half a mile from this, is a garden, called Hamlet's Garden, said, by tradition, to be the spot where the murder of his father was perpetrated. Long. 12. 54. E. Lat. 56. 0. N.

CROTALUS (*Enyel*). In that article, plate 59 should have been referred to instead of 89.

CROUCH, a river of Essex, which rises near Horndon, and flowing eastward, divides the hundred of Rochford from that of Dengy, and falls into the German Ocean, between Burnham and Foulness Island. The Wallfleet and Burnham oysters are the product of its creeks and pits.

CROUP, in medicine, an inflammation of the larynx, affecting children under ten years of age, attended with an exudation of coagulable lymph, which acting as an extraneous body, excites a spasmodic stricture of the *rima glottidis*, first inducing a difficulty of breathing, with a peculiar stridulous noise, and in a short time suffocation.

This disease being commonly fatal, requires an early attention to the symptoms, and a rigorous mode of treatment, for want of which it is probable many children have been lost :

6 X

though it is evident from dissection, that it is of an inflammatory nature; yet from reasoning, as well as from some cases which have lately occurred, there can be little doubt that it is the spasmodic contraction of the lungs, which is the immediate cause of death.

As soon as possible a brisk emetic should be administered for the purpose of freeing the patient from the coagulable lymph which is already secreted. Topical bleeding, by means of leeches, should immediately succeed, and the discharge encouraged. As soon as it diminishes, a blister, so large as to cover the whole throat, should be applied, and suffered to lie on for thirty hours or longer.

As soon as the emetic has operated sufficiently, opium in large doses should be administered, by which means the breathing will in general be soon relieved; but should it become more difficult in the course of a few hours, the emetic is to be again repeated, and after its operation the opium again employed. This practice is to be alternately used till such time as the patient is out of danger, which will in general be in the course of three or four days.

Mr. Kendrick, surgeon in Warrington, who first suggested the necessity of employing opiates in the croup, asserts, that this treatment has succeeded in four cases out of five under his care.

CUBAGUA, an island of South America, between that of Margareta and Terra Firma, subject to Spain. Long. 54. 30. W. Lat. 10. 15. N.

CUBAN, a large river, formed by the junction of a great number of streams that rise in the countries comprehended between the Black Sea and the Caspian. Taking a westerly direction, it divides the Abkhaz and Circassians from part of Taurica, and then falls into the Black Sea.

CUBAN, or CUBAN TARTARY, a country of Asia, bounded on the W. by the sea of Adoph; on the N. by the river Don, which separates it from Europe; on the E. by the desert of Afracan; and on the S. by the river Cuban, which divides it from Circassia and the country of the Abkhaz.

CUCKFIELD, a town of Suffex, with a market on Friday. It is 13 miles N. W. of Lewes, and 40 S. by W. of London. Long. 0. 12. W. Lat. 51. 4. N.

CUDDAPA, a town of the peninsula of Hindoostan, ceded by Tippoo Sultan to the nizam of the Deccan. It is seated on the river Pennar, 95 miles W. by N. of its entrance, at Gangapatnam, into the bay of Bengal, and 140 N. W. of Madras. Long. 78. 47. E. Lat. 14. 3. N.

CUDWORTH (Ralph), a very learned divine of the church of England in the 17th century. In January 1657 he was one of the persons nominated by a committee of the parliament to be consulted about the English translation of the Bible. In 1678 he published his *True Intellectual System of the Universe*; a work which met with great opposition. He likewise published a treatise, entitled *Deus justificatus*; or, "The divine goodness of God vindicated, against the assertions of absolute and unconditional reprobation." He embraced the mechanical or corpuscular philosophy; but with regard to the Deity, spirits, geni, and ideas, he followed the Platonists. He died at Cambridge in 1688. The late earl of Shaftesbury styles him an excellent and learned divine, of highest authority at home, and fame abroad. His daughter Damaris, who married Sir Francis Matham, of Oates in Essex, was a lady of genius and learning; she had a great friendship for Mr. Locke, who resided several years at her house at Oates, where he died in 1704.

CUFF (Henry), the unfortunate secretary of the unfortunate Earl of Essex, was born at Hinton St. George in Somersetshire, about the year 1560, of a genteel family, who were possessed of considerable estates in that county. In 1576 he was entered of Trinity College, Oxford, where he soon acquired

considerable reputation as a Grecian, and disputant: He obtained a fellowship in the above-mentioned college; but was afterwards expelled for speaking disrespectfully of the founder. He was, however, soon after admitted of Merton College; of which, in 1586, he was elected probationer, and, in 1588, fellow. In this year he took the degree of master of arts. Some time after, he was elected Greek professor, and, in 1594, proctor of the university.

When he left Oxford is uncertain; nor are we better informed as to the means of his introduction to the Earl of Essex. When that nobleman was made lord lieutenant of Ireland, Mr. Cuff was appointed his secretary, and continued intimately connected with his lordship until his confinement in the Tower; and he is generally supposed to have advised those violent measures which ended in their mutual destruction. The earl indeed confessed as much before his execution, and charged him, to his face, with being the author of all his misfortunes. Mr. Cuff was tried for high-treason, convicted, and executed at Tyburn on the 30th of March, 1601. Lord Bacon, Sir Henry Wotton, and Camden, speak of him in very harsh terms. He was certainly a man of learning and abilities.

He wrote two books; the one entitled, *The Differences of the Ages of Man's Life*; the other, *De Rebus Gestis in Sancto Concilio Niceno*. The first was published after his death; the second is still in manuscript.

CUJAS (James), in Latin *Cujacius*, the best civilian of his time, was born at Toulouse, of obscure parents, in 1520. He learned polite literature and history; and acquired great knowledge in the ancient laws, which he taught with extraordinary reputation at Toulouse, Cahors, Bourges, and Valence, in Dauphiny. Emanuel Philibert, duke of Savoy, invited him to Turin, and gave him singular marks of his esteem. Cujas afterwards refused very advantageous offers from Pope Gregory XIII. who was desirous of having him teach at Bologna; but he chose rather to fix at Bourges, where he had a prodigious number of scholars; whom he not only took great pleasure in instructing, but assisted with his substance, which occasioned his being called the *Father of his Scholars*. He died at Bourges in 1590, aged 70. His works are in high esteem among civilians.

CULLEN (William), an eminent physician and medical teacher, was born in 1712, in the county of Lanerk in Scotland. He served an apprenticeship to a surgeon and apothecary in Glasgow, and afterwards went several voyages to the West Indies, as surgeon to a trading ship. He at length settled at the town of Hamilton, practising chiefly in the medical and pharmaceutical branches. It is a very singular circumstance in the history of medicine, that William Hunter, afterwards so eminent as an anatomist and accoucheur in London, should at one time have been partner with Cullen in an inconsiderable country town. It appears, however, that, at this early period of their lives, neither of them limited his ambition to such a confined circle; for it was the spirit of their partnership to provide means for enabling them alternately to enjoy those further advantages of education which scanty circumstances had hitherto denied them. In consequence of this agreement, Cullen studied one winter at the university of Edinburgh, while Hunter was practising on the common account. Hunter, the next year, visited London, and followed his fortune in that metropolis, under the auspices of Dr. Douglas the anatomist. Cullen, during his abode at Hamilton, attracted the notice of the Duke of Argyll, who happened to be on a visit in the neighbourhood, and was intent upon some chemical researches. It was not difficult for a man of his discernment to discover in the young apothecary a person superior to the station he then occupied. Soon after, a sudden illness of the Duke of Hamilton, whose seat is adjacent

to the town of his name, occasioned Cullen to be sent for; and his treatment of the case appeared so judicious to Dr. Clark of Edinburgh, who was afterwards consulted, that he became his liberal encomiast. Cullen's improving prospects induced him to form a matrimonial connection with an amiable woman, the daughter of a neighbouring minister. He afterwards took the degree of doctor of physic, and settling at Glasgow, was appointed, in 1746, chemical lecturer in the university of that city. Here he began to display those talents for teaching, which ever afterwards so advantageously distinguished him. His enunciation was distinct, his manner lively and familiar; and he peculiarly excelled in the art of clear and methodical arrangement. He soon became a great favourite with the students, and rendered chemistry an object of ardent pursuit among them, the effects of which were afterwards happily exemplified in the discoveries of his pupil, the celebrated Dr. Black. His private practice kept pace with his growing reputation; and, in 1751, he was more directly engaged in the service of the healing art, by his appointment of professor of medicine in the university. The fame of Edinburgh as a medical school has by nothing been so much promoted as by the vigilance of its curators to seize upon every man of distinguished merit within their reach, and incorporate him among their professors. Thus, on the death of Dr. Plummer, the chemical professor, in 1756, Dr. Cullen received an unanimous invitation to the vacant chair; and he did not hesitate to quit all his advantages at Glasgow for a station in the university of the Scottish metropolis. Here he soon arrived at that extraordinary degree of academical popularity which for so many years distinguished him beyond all his brethren, and for which he was indebted, not only to his merit as a teacher, but to the laudable pains he took to ingratiate himself with his pupils. He was cordially attentive to all their interests, admitted them freely to his house, conversed with them on the most familiar terms, solved their doubts and difficulties, gave them the use of his library, and in every respect treated them with the affection of a friend, and the regard of a parent. It is impossible for those who personally knew him in this relation ever to forget the ardour of attachment which he inspired. His influence upon young minds was augmented by the novelty of his opinions, and the freedom of his animadversions upon the medical systems then chiefly in vogue, but which undoubtedly presented several points of attack. The older professors had all been educated in the Boerhaavian school, and though men of merit, were naturally prejudiced in favour of the doctrines they had imbibed. Dr. Cullen called in question some of the fundamental principles of the theory of the Leyden professor, especially those which depended upon the humoral pathology. He introduced new speculations, which, if not always satisfactory, never failed to be ingenious, and afforded animated topics for the debates and discussions of the students. Whilst he was chemical professor, he had no public opportunity of delivering his medical opinions, except in the clinical lectures which fell to his share in course. Indeed, at the death of Dr. Alison, in 1760, he was desired to finish the course of *materia medica* which that professor had begun; and this gave occasion to some further display of his systems. It was not till the decease of Dr. Whytt, in 1766, that a proper medical chair became vacant. The body of students then made a great effort to procure Dr. Cullen's appointment to the practical professorship; but this was occupied by Dr. Gregory, who succeeded to Dr. Rutherford. A compromise, however, took place between them, by which they agreed to give lectures on the theory and practice of physic in alternate years: and some have accounted this period to have been the most flourishing for medical science which Edinburgh ever witnessed. This arrangement was broken by Dr. Gregory's lamented death; after which Dr.

Cullen continued to hold the practical chair till within a few months of his own decease. His private employ kept pace with his academical reputation, and he rose to be the first physician in point of practice in Scotland. He was likewise frequently consulted from England, and other countries, which were filled with practitioners who had been his pupils, and retained a high veneration for his talents. Dr. J. Brown, from being the votary, became the rival and opponent of Dr. Cullen, who at length began to feel some of that jealousy towards an innovator which he himself had once inspired. The history of academical squabbles would improperly be introduced into this sketch; we therefore close the life of this eminent person with mentioning, that he died on February 5, 1790, in his seventy-seventh year. Notwithstanding the sources of emolument he enjoyed, a large and expensive family, and inattention to economy, so far exhausted his income, that he left a slender provision for the survivors, which was augmented by a pension from the crown, granted upon the ground of his having been king's physician for Scotland.

Dr. Cullen's scientific merits are now more particularly to be discussed. As a chemist, no considerable discovery can be ascribed to him; but he was an extremely useful teacher of the science, from the liberal and comprehensive views he took of it, and the great clearness of method with which he treated it. He likewise, from an accurate collection of facts, formed very complete histories of several of its departments, particularly those connected with medicine and the *materia medica*; and it is certain that no man in these kingdoms has done so much to render chemistry a popular study, especially among the medical faculty.

His character, as a preceptor and improver in the theory and practice of physic, is to be estimated from the works he published, as a sort of text-book of his lectures, and of which various successive editions appeared, enlarged and altered according to the progress of his professional labours. Of these the principal is that which, in a bald translation of the Latin term, *Præmiæ Linææ*, used by Haller and others, he entitled "First Lines of the Practice of Physic." The complete edition of this work appeared in 1784, in four volumes octavo. Regarding the affections of the motions and moving powers of the animal economy as the leading enquiry in considering the diseases of the human body, he assumes the general principles of Hoffman, but corrected and extended in their application. He disclaims, however, all those hypothetical opinions which are usually called theories; and asserts, that the doctrines he lays down are only inductions from that generalisation of *facts* relative to the sound and diseased body, which it has been his great business to collect. Nor has any systematist more fairly deserved the praise of being a faithful collector of facts, and allowing them all due weight in his reasonings. He has not, however, been contented with a merely empirical basis for medical practice, but has always endeavoured to investigate the proximate cause of diseases, and to build upon it a consistent method of cure. The most remarkable of his attempts of this kind is his doctrine of the proximate cause of fevers, in which he endeavours to prove the co-existence of spasm and atony in the body. Whatever be thought of the subtle reasonings upon which his opinions in this and other instances are founded, no candid judge will deny the great merit derived to his work from the excellent descriptions and sagacious discriminations it contains, and the full and commonly just views of practice which it displays. Dr. Cullen affords the rare and instructive example of a man naturally addicted to all the refinements of speculation, who yet pays such a respect to experience, as to submit to its decision in all points of practice, even at the hazard of appearing inconsistent with his own doctrine. This disposition, which has given his opponents some advantage

over him in argument, greatly adds to his value as a guide in an art to uncertain in its principles as that of medicine. Another of his class-books is his "Synopsis Nofologiae Methodica," of which the third edition, in two volumes octavo, appeared in 1782. This contains the several nosologies of Sauvages, Linnaeus, Vogel, and Sagar, with one of his own, meant as an improvement upon all these. As methodical arrangement was one of his peculiar talents, it might be expected that he should succeed in this task as far as the nature of the subject would admit; and, without disparagement to his predecessors, it may be pronounced, that he has improved upon them all in the elegance of his characteristic definitions, and the judiciousness of his distribution. The "Lectures on Materia Medica," which we have mentioned as drawn up by Dr. Cullen on an emergency, were thought to ingenious, that copies of them were multiplied among the students; and at length, in 1772, one of them surreptitiously reached the press. The doctor obtained an injunction to stop the sale of this imperfect publication; but, with some corrections, it was afterwards suffered to proceed. He promised, however, at some period to give an improved edition of his own; and this appeared in 1789, in two volumes quarto. This is a work very different from the common systems on the subject, and indeed, as a critic has observed, rather deserves the title of the philosophy of the materia medica than the simple history of it. The arrangement is taken from the medical indications, and to each class are prefixed introductory observations, which form a system of therapeutics. Many of the general doctrines of medicine are likewise detailed. As it contains a number of the mature opinions of the author on the most important topics, it is well entitled to attention, although it is in many points defective as a treatise on the subject assigned. Its general spirit is that of medical scepticism; of a man who has read much, thought much, and determined little: and it has been remarked of Dr. Cullen's writings in general, that he has been more successful in demolishing the systems of others, than in establishing his own. A pamphlet Concerning the Recovery of Persons drowned and seemingly dead, 1775, is to be added to the list of his publications.—We are indebted to the popular biographical work of Dr. Aikin for the foregoing particulars.

CULM, a town of Western Prussia, with a bishop's see, seated near the Vistula, 60 miles S. of Dantzic. Long. 18. 30. E. Lat. 53. 24. N.

CULMORE, a town of Ireland, in the county of Londonderry, seated on the coast of Loughfoyle, five miles N. of Londonderry. Long. 7. 3. W. Lat. 55. 8. N.

CULMSEE, a town of Poland, five miles from Culm, whose bishop generally resides here.

CUMANA, a town of S. America, in Terra Firma, capital of a province of the same name. Long. 63. 35. W. Lat. 9. 46. N.

CUMBERLAND (Richard), a very learned English divine in the latter end of the 17th century, was son of a citizen of London, and educated at Cambridge. In 1672 he published his excellent Treatise of the Laws of Nature; and in 1686, an Essay toward the Jewish Weights and Measures. After the revolution he was nominated by King William to the bishopric of Peterborough, without the least solicitation on his part. He pursued his studies to the last; and the world is obliged to him for clearing up several difficulties in history, chronology, and philosophy. After the age of 83, he applied himself to the study of the Coptic language, of which he made himself master. He was as remarkable for humility of mind, benevolence of temper, and innocence of life, as for his extensive learning. He died in 1718.

CUMBRIAY; GREATER AND LESSER, two little islands in the Frith of Clyde, to the E. of the isle of Bute. The former

is remarkable for its excellent free-stone quarries, and the ruins of an ancient cathedral dedicated to St. Columba. Upon the latter is a lighthouse.

CUPAR, a royal borough of Scotland, in Fifeshire, and the county-town, 8 miles N. by E. of Falkland, in a rich valley, on the N. side of the river Eden.

CURIA-MARIA, an island of Asia, on the coast of Arabia Felix, opposite the mouth of the river Prim. Long. 55. 25. E. Lat. 17. 0. N.

CURING, a term used to denote that process which is applied to any animal or vegetable article of food, with a view to preserve it for future use. Salting, drying, pickling, or smoking, are the common means used for this purpose. The following is the specification of the patent granted to Mr. Batley, of Streatham, Surrey, for a new method of curing herrings, sprats, &c.—"After severing the head, and taking out the entrails of the herrings or sprats, salt the body of the fish with bay or rock, or the common salt, in the casks (if not sufficiently salted as sea fish), but the bay or rock salt is preferable, as the common is more apt to absorb the pickle, and occasion the fish to rust. In the next place pack the fish in a cask, in the usual way, and between every layer sprinkle a small portion of salt, and also pickle, sufficient to cover the fish. Such pickle is to be made with one pound of bay salt, four ounces of saltpetre, and from two to four pounds of melasses (to suit different palates), to a gallon of spring water, if to be procured, and boil the same till the whole of the ingredients are dissolved. (River water may answer the purpose, but spring water is preferable.) When the fish are so packed, leaving a vacuum between two and three inches of the head of the cask, for a full portion of pickle, then let the cask be headed up, and properly coopered, with a cork-hole, either in the head or centre, through which may be poured a further supply of the pickle, for the preservation of the fish; and when the herrings or sprats, but particularly the latter, are intended for travelling, it may be advisable to put a false top, bored with holes, between the fish and cask-head, in order to prevent their being too much shaken: the same proportion of any sugar might be used as a substitute for melasses, but the extra price would probably be considered as an impediment; and from one to three months should be allowed for curing, in order to give the fish a full flavour before they are used, smoked or dried. The above pickle would answer for flavouring the fish in their original state, if needful; but, on account of the oil and fish contained in the heads and roes, the preferable mode of curing and preserving the body of the fish is by severing the head from, and taking out the entrails, as the only effectual means of eradicating the noxious qualities which would otherwise adhere to them. And, in curing sprats, it is expedient to sprinkle a larger quantity of salt in proportion between each layer than is requisite for the herrings when packed in the cask. And as the sprat casks will seldom exceed ten gallons, a vacuum of about one inch from the head for casks of that dimension will be sufficient."

CURL, a disease affecting the plant of the potatoe, very well known to agriculturists. The remedy for this is a matter of such national importance as to induce the Society for the Encouragement of Arts, Manufactures, and Commerce, to offer their gold medal, or thirty pounds, to the person who should discover the nature and cause of it, and point out an effectual cure. They received the three following papers; and being desirous of encouraging every attempt to ensure success in the culture of that valuable vegetable, divided the pecuniary premium equally among the three candidates.

From Mr. Hollin's paper we select the following abstract:—"The curl in potatoes," says he, "is a disease which admits of three different stages or degrees.

"1st. The *half-curl*ed plants, have leaves somewhat long, and curled only in a moderate degree: they produce a tolerable crop, if the summer be not very dry; but if otherwise, the potatoes will be small and watery.

"2d. The *completely-curl*ed plants, seldom more than six or seven inches high: they soon ripen and die. The potatoes are generally smaller than a nutmeg, of a rusty red colour, and unwholesome as food.

"3d. The *corrupted potatoes*, or those in which the vegetative power is nearly destroyed, never appear above ground. The feed may be found at Michaelmas, as fresh, to appearance, as when it was sown, with a few small potatoes close to it.

"The *first cause* of the curl in potatoes must be traced to the manner in which the feed was raised the preceding year.

"If the potatoes be set late in the season, that is, from the middle of May to the middle of June, in a rich soil, well manured, having a southern aspect, and if the summer should be hot and dry till (we will suppose) the beginning of August, when the blow of the plants has fallen off, then the feed will be exhausted in feeding the plant only; and very few potatoes will appear. Should the weather now become moist and genial, the plants, especially if they should be earthed, will blow fresh, and a plentiful crop of very large potatoes may yet be produced.

"These potatoes are perfectly fit for use as food; but as they were produced from the stalk of the plant, after the feed itself was exhausted, they will be defective in moisture and vegetative power: and the plants which proceed from them the following year will be found to be curled."

Second cause. "The curl," says Mr. Hollins, "may be produced without manure or earthing, provided the potatoes be sown (at the end of May) thick together, in a rich soil, and covered with green fern, or other litter, before the plants appear. The rain rots the fern or litter, and enables it to penetrate as a manure to the roots; and the plants are forced, as in the preceding experiment, to a second growth, and blow. The feed thus raised produced plants that were curled."

"The forcing potatoes by cultivation, as above described, I find to be the cause of the curl, both from my own experiments, repeated for several years successively, and also from the observations I have made upon the practice and ill success of my neighbours.

"It is well known that the flowers of many plants, such as the poppy, the rose, and many others, are much altered by cultivation; they become *double*, the stamina are converted into petals, the generic character is lost, they become what botanists call monsters; the parts of generation being changed, no seed is produced. If I may be allowed to consider any part of a plant in which the vegetative power resides as a feed, it will be found that rich cultivation produces, if not absolutely the same, at least a similar imperfection in the potatoe; for the flower and the bulbous root are both enlarged by cultivation. In the flower little or no seed is produced: in the potatoe, the vegetative power is impaired or destroyed, according to the degree of the disease.

"It is observable that, wherever the vegetative power is impaired, there is always a deficiency of moisture; which confirms my opinion, mentioned before, and is itself proved by the following experiment.

"Both healthy and curled plants may be raised from the same potatoe, in the following manner:

"Dig up, in the beginning of October, some potatoes raised as is described in the preceding pages. Amongst the largest will be found some that have, in different parts, different degrees of moisture, the least at the butt, and the most at the crown end, the quantity of moisture gradually increasing from the butt to the crown. Take one set from the crown and ano-

ther from the butt: the former will produce an healthy, the latter a curled plant. The curl-producing potatoes are also observed to be drier both before and after boiling, and are boiled in a shorter time."

The mode of preventing the curl in potatoes recommended by Mr. Hollins is this: he says, 1st. "The best time of setting is from the beginning of April to the middle of May. Make ridges a yard asunder: put your manure first into the trench, and with moderation: let the potatoes in a triangular form, five or six inches asunder, cover them with the soil to the thickness of five or six inches. There is but little danger of laying on too much of the soil: the deeper are the sets, the better will they be protected from the scorching heat of the sun, if the season should be dry. This distance of five or six inches is so small as to prevent the plants growing too rank, and yet sufficient for each of them to be exposed to the sun and the air.

"2dly, When they have grown to the height of six or seven inches above the ground, you must not earth them, as is the usual practice. You must take away the weeds, and may draw a little mould to them; but you must be careful to do it before the blossom-buds appear, which time is generally about the end of June.

"They will now require no further care, excepting that of weeding.

"I am of opinion that early setting is advantageous, on account of the greater chance of early rain, which will be very beneficial to the plants if the summer should be dry. By this process, the plants will be healthy; the young potatoes will be formed in due season; they will grow gradually; the plant will ripen and die in due time, and will not be forced into a second growth by the rain which may fall in September. The tap being thus left in the potatoe, it becomes a feed endowed with an unimpaired perfect vegetative power, and the plants which are raised from them will be found to be entirely free from the curl.

"N. B. The potatoes may be dug as soon as they can be handled without crushing the peel, that is, about the end of September.

"Sound potatoes are procured with the greatest certainty from earth that has been peeled and burnt: the soil thus prepared is well suited to the growth of potatoes. In this they grow gradually, and are not forced beyond their natural size: in doubtful feed, it is safest to plant the smallest potatoes *whole*.

"The foil the most likely to produce the curl, is that which is rich in itself, much manured, and has a southern aspect. In other situations, where the soil is not rich, and the garden is cold, either from its being upon the side of a hill, or exposed to the north, the curl has not yet appeared; which is known to be the case in the mountainous parts of Radnorshire and Montgomeryshire. This is perfectly consonant with my theory; for where the soil is poor, and the situation cold, the plants cannot be forced into a second growth by earthing and manure.

"I do not mean to dissuade those who are anxious to raise large crops for immediate use, from earthing and manuring to the utmost extent; I only caution them against using potatoes so raised for *feed*. By earthing and manuring, you will doubtless raise large crops of large potatoes perfectly good, as food, but imperfect as feed; for the vegetative power will be impaired by this forcing cultivation. Hence it will be the interest of every prudent cultivator, to allot a portion of his potatoe-garden to the raising of feed-potatoes. If the directions which I have given be followed, I have not the least doubt of success; at least I am certain that the curl will not make its appearance."

Mr. Pitt's paper.—"Having been a grower of potatoes," says he, "upon a considerable scale, for these ten years, I write wholly from experience: my annual growth has generally been from five hundred to one thousand bushels. I have frequently had a few curled, but not for several years, unless I planted curled sorts in small quantities, on purpose for observation. The curl in potatoes is doubtless owing to a degeneracy in the feed; to the particular species or variety being worn out; by too great a sameness, and too long planting on the same sort of land: and this degeneracy is by no means peculiar to the potatoe; every known plant, and perhaps even animal, is subject to a similar degeneracy. Wheat, sown too long on the same spot, without changing the feed, will generally become smut and hen-corn. — I have known barley, by being sown nine or ten years on the same kind of soil, degenerate to the lightness of oats; and oats, from the same cause, become little more than husk and chaff. Peas, too long sown without change, ripen later, and become so unkindly, that the pods, on the upper part of the haulm, never fill. To consider the same idea, and apply it in an instance or two to the animal creation, I have known a good breed of hogs, by repetition of breeding male and female from the same farrow, become so rickety, that they could not be reared; and have very credible accounts of the same effects taking place in the human species, by confining intermarriages to two or three families for generations.

"I hope this digression will be excused, as tending to illustrate the main subject, by making the cause of the disorder, in question, apparent.

"The cure, I have no doubt, consists in planting sorts that have hitherto retained their health and their perfection; (and many such sorts there are; fresh varieties are annually raised, and may be multiplied almost to infinity, by sowing the bell or natural seed of the potatoe); and indeed it is the duty, as well as interest, of every cultivator, whether of potatoes, or any other vegetable, to procure his seed from as perfect a plant as possible, and by no means to use the seed of a worn-out, degenerate plant.

"I have never understood, that the curl in potatoes has been, in this country, by any means formidable to the attentive cultivator. No one in their senses would plant a degenerate sort but upon a narrow scale, nor indeed is there the least occasion: for the bounty of nature has always at hand plenty of substitutes, equal or superior in quality to former sorts, even when they were in perfection. The varieties that I have known fail by curling, in this country, are only three: their provincial names are, first, an early sort, called here *Pretty Bettys*; in lieu of which are introduced *Champions* and *Golden Balls*, both excellent early sorts: secondly and thirdly, the old *Winter Reds*, and *Pink Eyes*, have both failed, and we have instead of them, *Aylesbury Whites*, the *Clufter Potatoe*, the *Ox Noble*, red and white *Surinam* for cattle; a dark purple kind, called by some the *Pomegranate Potatoe*; and many other valuable sorts, which never have yet curled. The rational remedy, therefore, undoubtedly, is the raising and introducing of fresh varieties; a practice which has never yet been interrupted by any difficulty."

Mr. Holt's paper.—"On the cause and prevention of the curl in potatoes," says Mr. Holt, "I beg leave to offer the following thoughts, being a subject of no small importance to the farmer, and to which I have paid not a little attention.

"The cause of this disease, as far as I can judge, does not arise from peculiarity of soil, variety of manure, difference of season (dry or moist): the cause, therefore, whatever it may be, it should seem, originates from the set, which, when once infected, I imagine is incurable; and the disease or curl appears to be nothing more than a total degeneracy of the

plant, by being worn out, through want of change of feed, upon the same soil, with probably some other causes co-operating.

"It is a well-known fact, to every experienced farmer, that almost every species of grain and vegetables require repeated renewal, or change from different soils: or they wear out, (as the phrase is), yield but imperfect crops, if continued too long; and defeat the cultivator in his expectations of reaping benefit. Why may not this too cause the same effect in potatoes, by their being too repeatedly planted, and occasion the blasted, early-matured appearance of the stems, which is always followed by a failure of crop.

"In confirmation of the above theory, this district for some years suffered great injury from curled potatoes. As the disease had but then lately made its appearance, the cultivators were at a loss for a remedy.—This was obtained by totally discarding their former feed-plants; and of late years large quantities have been annually imported from Scotland.

"This practice has been attended with success: few crops, I believe I may venture to say none, have been infected with the disease, if renewed; but if the same seed was imprudently, for a few years, continued upon the same soil, some plants would appear infected; and if still continued longer, the disease, instead of being *partial*, would soon become *total*, with few exceptions. The custom now is, to import every year from Scotland.

"There may be other reasons which cause a degeneracy of wearing out of the plant.—Every seed has its peculiar season, when it is most proper to be committed to the earth. In some, the budding of certain plants, or the blowing of flowers, indicate this precise moment to the attentive cultivator: the month, or even the day of the month, is his only guide in others. To a few of these the most favourable time is very limited, so very limited, that the winter turnip will not (in this district) yield a crop, if its seed be not sown within a very few days before or after the 20th of July; but better, if five days before this period, than the same number of days afterwards. From the 20th of March to the end of April is a proper season for planting most of the kinds of the winter potatoe: but this root, the friend and great support of the labouring man, is not so very shy of her favours; productive crops have been obtained when planted even in July.—Time, however, for acquiring sufficient maturity, is not allowed from such late planting; for the crop, though productive, is not perfect, being neither so solid nor palatable; and this may be one cause of accelerating a decay, or bringing on the curl.

"The potatoe is also liable to other disorders: in very dry seasons, excrescences will arise, vulgarly called the *scab*; in moist seasons, little holes or cavities appear, called the *canker*; and both these disorders increase according to the length of time they remain in the earth after having acquired maturity.—It is more than probable, that these disorders may hasten the decay, and cause the curl.

"One method of preventing the disease, namely, by changing the seed, has been already mentioned: another source of prevention offers, from raising new kinds from the seed or apple of the plant, or the same kinds renewed again from the seed. Raising new kinds from seed, however, requires no small portion of discernment; for the seed from the same plant will produce so many varieties, that it requires nice judgment of the cultivator properly to select. Great numbers, from inspection only, will be weeded out and rejected; and of those retained, more will be again rejected the succeeding and following years: of the remaining few, there may different characters still exist; such as ill or well-flavoured, close or coarse-grained, productive, non-productive.

tive, &c. &c. Each may have their respective value: but I think it may be generally asserted, that the finer kinds sooner degenerate; the coarse kinds, which are almost, if not always, more productive, retain their vigour the longest. The following example confirms this opinion.

"Spring, 1785.—I procured a new kind of potatoe, called a Dabb, lately raised from seed; where, I know not: the character of which was large, coarse-grained, strong-flavoured, and of course rejected from the table; but being very productive, was useful for cattle. The last year it was so much improved, as to be no longer rejected: it still retains the quality of being productive, even so much as yielding, this present year, six bushels from every square perch. It should be observed, that the present very luxuriant crop may be in great measure owing to having been planted on a virgin soil, which was never before improved, or broken up; very little dung was used. Here is an evident change for the better; the plants are vigorous, and there is at present no appearance of decay: this new soil may be the means of preserving the plant a few years longer; but a total change of seed will, in time, become absolutely necessary.

"Hence, it should appear, that although the disease, after the present stock has been, to a certain degree, infected, can never be cured, yet means may be taken for prevention: and that this is the case in this district is evident; few crops, of late years, having failed, by being much infected with this disorder; for, wherever the curl has appeared, in ever so small a degree, that stock has been rejected by the attentive cultivator, and new seed obtained.

"It was so late as the year 1765, when the potatoe was first imported from its native soil, America, into Ireland; and afterwards (owing as is reported, to a shipwreck) they were planted upon the sea-coast, in Lancashire, from whence their cultivation has been progressive, from the west, through every part of the kingdom; in some of which but very lately. It is also imagined, that this disease first appeared in this very district of the kingdom wherein they were first cultivated; and this happened about the year 1764: a remarkable circumstance at which time I yet well remember:—a person, full of enterprise, observing the curl in a few stems of a certain crop, and that they at the same time decayed, or arrived at maturity sooner than the rest, had them carefully selected out, imagining he had luckily obtained, somehow, a new and early kind; and had all of them planted the next season: that he was disappointed of his succeeding crop was evident; but from what cause he was puzzled.

"I am the more encouraged to offer these hints, for that, after having drawn them up, in the manner here sent, I read them over to a very intelligent farmer in this neighbourhood, who said that these thoughts totally corresponded with his own. I have shewn them also to a respectable clergyman, who, to his other many excellent qualities, is always ready to communicate information, and has favoured me with the following extract from a private letter.

"A labouring man in my neighbourhood has got a very good potatoe: the only fault is, that out of four plants, three of them are abominably curled; on which account I desired he would give me four potatoes. From each potatoe I took a shoot, not a set, in order to see if the shoots would be curled: they were not: so, possibly their not being curled may be accidental, or possibly the curl may arise from the set planted. Another year, I will plant a dozen or more, of these potatoe-shoots: then, if there should be no curl, I shall be clearly of opinion, that the curl arises from some disease in the set. What I mean by shoot, is—I put

three or four sets into a flower-pot; when they have shot to be about two inches high, and have fibres, I take the sets up, and with a knife cut the shoots off, leaving not the least piece of a set on the shoot. I then plant the shoots."

"It should appear, from the above ingenious experiment, of which future trials will confuse or confirm the fact, that it corroborates the above theory, by proving the disease in the set; and which, when the cause or seat of the disorder is lopped away, the cure is effected by the force of nature to heal itself, and the power of vegetation on the small fibres, which retain newly-acquired life, though from an infected parent stock.

"The nature of vegetation is so mysterious, that we must acknowledge our ignorance in her wonderful process. We know that many varieties of fruits may, by a single bud of each, be inoculated upon one and the same single stock; and that, from this one root or fountain-head, may be obtained the different fruits therein deposited; but by what law of attraction or repulsion this common stock or parent can divide, assimilate, correct, and adjust, the different particles of matter of which each fruit is distinguished, by shape and flavour, is beyond our reach to know. It is true, that but a very small part of the food of plants or fruits is filtered through the roots of the plants: the leaves, the bark, the wood, imbibe from the atmosphere, and perform their task: but being of different shape, texture, and grain, each has its separate and particular mode of operation, and thereby causes different effects. Nor yet are we able to say, what it may be that gives the different flavours to fruit; whether from the component particles of matter differently arranged, or whether from the separate and component parts being of different shapes, &c. &c. These are secrets hitherto withheld, and probably ever will be hid from the search of man."

CURSOLIERS, a small island of Livadia, in the gulf of Patras, formerly called Echanades.

CUSSET, a town of France, in the department of Allier, and late province of Bourbonnois, 17 miles N. of Roanne. Long. 4. 5. E. Lat. 46. 17. N.

CUSTOM and **FABR** (*Encycl.*). In our original article we omitted the necessary consideration of the *effects of custom and habit in the animal economy*. These may be reduced to five heads. 1. On the simple solids. 2. On the organs of sense. 3. On the moving power. 4. On the whole nervous power. 5. On the system of blood-vessels.

1. *Effects on the simple solids.* Custom determines the degree of flexibility of which they are capable. By frequently repeated flexion, the several articles of which these solids consist are rendered more supple and moveable on each other. A piece of catgut, e.g. when on the stretch, and having a weight appended to its middle, will be bended thereby perhaps half an inch; afterwards, by frequent repetitions of the same weight, or by increasing the weight, the flexibility will be rendered double. The degree of flexibility has a great effect in determining the degree of oscillation, provided that elasticity is not affected; if it go beyond this, it produces flaccidity. Again, custom determines the degree of tension; for the same elastic chord that now oscillates in a certain degree of tension, will, by frequent repetition of these oscillations, be so far relaxed, that the extension must be renewed in order to produce the same tension, and consequently the same vibrations, as at first. This appears in many instances in the animal economy, as when different muscles concur to give a fixed point, or tension, to each other: and thus a weakly child totters as it walks; but by giving it a weight to carry, and by thus increasing the tension of the system, it walks more steadily. In like manner the fulness of the sys-

tem gives strength, by distending the vessels every-where, and so giving tension: hence a man, by good nourishment, from being weak, acquires a great increase of strength in a few days; and, on the other hand, evacuations weaken by taking off the tension.

2. *Effects on the organs of sense.* Repetition gives a greater degree of sensibility, in so far only as it renders perception more accurate. Repetition alone gives lasting impressions, and thus lays the foundation of memory; for single impressions are but retained for a short time, and are soon forgot. Thus a person, who at present has little knowledge of cloths, will, by frequently handling them, acquire a skill of discerning them, which to others seems almost impossible. Many are apt to mistake this for a nicer sensibility, but they are much mistaken; for it is an universal law, that the repetition of impression renders us less acute. This is well illustrated by the operation of medicines; for all medicines which act on the organs of sense must, after some time, be increased in their dose, to produce the same effect as at first. This affords a rule in practice with regard to these medicines; it becoming necessary, after a certain time, to change one medicine even for a weaker of the same nature. Thus medicines, which even have no great apparent force, are found, by long use, to destroy the sensibility of the system to other impressions. But to this general rule, that, by repetition, the force of impressions is more and more diminished, there are some exceptions. Thus persons, by a strong emetic, have had their stomachs rendered so irritable, that 1-20th of the first dose was sufficient to produce the same effect. This, however, oftener takes place when the vomit is repeated every day; for if the same vomit be given at pretty considerable intervals, the general rule is observed to hold good. Thus two contrary effects of habit are to be noted; and it is proper to observe, that the greater irritability is more readily produced when the first impression is great, as in the case first given of the strong emetic. This may be further illustrated by the effect of fear, which is commonly observed to be diminished on repetition; which can only be attributed to custom: while, on the other hand, there are instances of persons, who, having once got a great fright, have for ever after continued slaves to fears excited by impressions of the like kind, however slight; which must be imputed entirely to excess of the first impression, as has been already observed. To this head also belongs the association of ideas, which is the foundation of memory and all our intellectual faculties, and is entirely the effect of custom; with regard to the body also, these associations often take place. And sometimes, in producing effects on the body, associations seemingly opposite are formed, which, through custom, become absolutely necessary; e. g. a person long accustomed to sleep in the neighbourhood of a great noise, is so far from being incommoded on that account, that afterwards such noise becomes necessary to produce sleep. It will be of use to attend to this in medical practice; for we ought to allow for, however opposite it may seem at the time, whatever usually attended the purpose we designed to effect. Thus, in the instance of sleep, we must not exclude noise when we want to procure rest, or any causes which may seem opposite to such an effect, provided custom has rendered them necessary.

3. *Effects on the moving fibres.* A certain degree of tension is necessary to motion, which is to be determined by custom; e. g. a fencer, accustomed to one foil, cannot have the same steadiness or activity with one heavier or lighter. It is necessary also that every motion should be performed in the same situation, or posture of the body, as the person has been accustomed to employ in that motion. Thus, in any surgical operation, a certain posture is recommended; but if

the operator has been accustomed to another, such a one, however awkward, becomes necessary afterwards to his right performance of that operation.

Custom also determines the degree of oscillation, of which the moving fibres are capable. A person accustomed to strong muscular exertions is quite incapable of the more delicate. Thus writing is performed by small muscular contractions; but if a person has been accustomed to stronger motions with these muscles, he will write with much less steadiness.

This subject of tension, formerly attributed to the *simple fibres*, is probably more strictly applicable to the moving: for, besides a tension from flexion, there is also a tension from irritation and sympathy; e. g. the tension of the stomach from food, gives tension to the whole body. Wine and spirituous liquors give tension; e. g. a person that is so affected with tremor as scarcely to hold a glass of any of these liquors to his head, has no sooner swallowed it, than his whole body becomes steady; and after the system has been accustomed to such stimuli, if they are not applied at the usual time, the whole body becomes flaccid, and, of consequence, unsteady in its motions.

Again, custom gives facility of motion. This seems to proceed from the distension which the nervous power gives to the moving fibres themselves. But in whatever manner it is occasioned, the effect is obvious, for any new or unusual motion is performed with great difficulty.

It is supposed that sensation depends on a communication with the sensorium commune, by means of organs sufficiently distended with nervous influence. We have found, that sensibility is diminished by repetition. And we have now to observe, that in some cases it may be increased by repetition, owing to the nervous power itself flowing more easily into the part on account of custom. Attention to a particular object may also determine a greater influx into any particular part, and thus the sensibility and irritability of that particular part may be increased.

But with regard to facility of motion, the nervous power, no doubt, flows most easily into those parts to which it has been accustomed: yet facility of motion does not entirely depend on this, but in part also on the concurrence of the action of a great many muscles; e. g. Winflow has observed, that, in performing any motion, a number of muscles concur to give a fixed point to those intended chiefly to act, as well as to others that are to vary and modify their action. This, however, is assisted by repetition, and the freer influx; as by experience we know the proper attitude for giving a fixed point in order to perform any action with facility and steadiness.

Custom gives a spontaneous motion also, which seems to recur at stated periods, even when the exciting causes are removed. Thus, if the stomach has been accustomed to vomit from a particular medicine, it will require a much smaller dose than at first, nay, even the very sight or remembrance of it will be sufficient to produce the effect; and there are not wanting instances of habitual vomiting, from the injudicious administration of emetics. It is on this account that all spasmodic affections so easily become habitual, and are so difficult of cure; as we must not only avoid all the exciting causes, even in the smallest degree, but also their associations.

Custom also gives strength of motion: strength depends on strong oscillations, a free and copious influx of the nervous power, and on dense solids. But in what manner all these circumstances have been brought about by repetition, has been already explained. The effect of custom, in producing strength, may be thus illustrated; a man that begins with lifting a calf, by continuing the same practice every day, will be able to lift it when grown to the full size of a bull.

All this is of considerable importance in the practice of phy-

fic, though but too little regarded; for the recovery of weak people, in great measure, depends on the use of exercise, suited to their strength, or rather within it, frequently repeated and gradually increased. Further, it is necessary to observe, that custom regulates the particular celerity with which each motion is to be performed: for a person accustomed, for a considerable time, to one degree of celerity, becomes incapable of a greater; e.g. a man accustomed to flow walking will be out of breath before he can run twenty paces. The train, or order, in which our motions are to be performed, is also established by custom; for if a man hath repeated motions, for a certain time, in any particular order, he cannot afterwards perform them in any other. Custom also very frequently associates motions and sensations: thus, if a person has been in the habit of associating certain ideas with the ordinary stimulus which in health excites urine, without these ideas the usual inclination will scarce excite that excretion; and, when these occur, will require it even in the absence of the primary exciting cause: e.g. it is very ordinary for a person to make urine when going to bed; and if he has been, for any length of time, accustomed to do so, he will ever afterwards make urine at that time, though otherwise he would often have no such inclination: by this means some secretions become, in a manner, subject to the will. The same may be said of going to stool: and this affords us a good rule in the case of constipation; for by endeavouring to fix a stated time for this evacuation, it will afterwards, at such time, more readily return. It is further remarkable, that motions are inseparably associated with other motions: this, perhaps, very often proceeds from the necessary degree of tension; but it also often depends merely on custom, an instance of which we have in the uniform motions of our eyes.

4. *Effects on the whole Nervous Power.* We have found, that, by custom, the nervous influence may be determined more easily into one part than another, and therefore, as all the parts of the system are strongly connected, the sensibility, irritability, and strength of any particular part, may be thus increased. Custom also has the power of altering the natural temperament, and of inducing a new one. It is also in the power of custom to render motions periodical, and periodically spontaneous. An instance of this we have in sleep, which is commonly said to be owing to the nervous power being exhausted, the necessary consequence of which is sleep, e.g. a rest of the voluntary motions to favour the recruit of that power: but if this were the case, the return of sleep should be at different times, according as the causes which diminish the nervous influence operate more or less powerfully; whereas the case is quite otherwise, these returns of sleep being quite regular. This is no less remarkable in the appetites, that return at particular periods, independent of every cause but custom. Hunger, e.g. is an extremely uneasy sensation; but goes off of itself, if the person did not take food at the usual time. The excretions are further proofs of this, e.g. going to stool, which, if it depended on any particular irritation, should be at longer or shorter intervals according to the nature of the aliment. There are many other instances of this disposition of the nervous influence to periodical motions, as the story of the idiot of Stafford, recorded by Dr. Plot (*Spectator*, No. 447.), who, being accustomed to tell the hours of the church-clock, as it struck, told them as exactly when it did not strike by its being out of order. Montaigne tells us of some oxen that were employed in a machine for drawing water, who, after making 300 turns, which was the usual number, could be stimulated by no whip or goad to proceed further. Infants, also, cry for and expect the breast at those times in which the nurse has been accustomed to give it.

Hence it would appear, that the human economy is subject

VOL. X.

to periodical revolutions, and that these happen not oftener may be imputed to variety; and this seems to be the reason why they happen oftener in the body than mind, because that is subject to greater variety. We see frequent instances of this in diseases, and in their crises; intermitting fevers, epilepsies, asthma, &c. are examples of periodical affections; and that critical days are not so strongly marked in this country as in Greece, and some others, may be imputed to the variety and instability of our climate; but perhaps still more to the less sensibility and irritability of our system; for the exhibition of medicine has little effect in disturbing the crises, though it be commonly assigned as a cause.

We are likewise subject to many habits independent of ourselves, as from the revolutions of the celestial bodies, particularly the sun, which determines the body, perhaps, to other daily revolutions besides sleeping and waking. There are also certain habits depending on the seasons. Our connections, likewise, with respect to mankind, are means of inducing habits. Thus regularity from associating in business, induces regular habits both of mind and body.

There are many diseases, which, though they arose at first from particular causes, at last continue merely through custom or habit. These are chiefly of the nervous system. We should, therefore, study to counteract such habits; and accordingly Hippocrates, among other things for the cure of epilepsy, orders an entire change of the manner of life. We likewise imitate this in the chin cough; which often resists all remedies till the air, diet, and ordinary train of life, are changed.

5. *Effects on the Blood-vessels.* From what has been said on the nervous power, the distribution of the fluids must necessarily be variously affected by custom, and with that the distribution of the different excretions; for though we make an estimate of the proportion of the excretions to one another, according to the climate and seasons, they must certainly be very much varied by custom.

On this head we may observe, that blood-letting has a manifest tendency to increase the quantity of the blood; and if this evacuation be repeated at stated times, such symptoms of repletion, and such motions are excited at these times, as render the operation necessary. The same has been observed in some spontaneous hæmorrhages. These, indeed, at first, may have some exciting causes, but afterwards they seem to depend chiefly on custom. The best proof of this is with regard to the menstrual evacuation. There is certainly something originally in females, that determines that evacuation to the monthly periods. Constant repetition of this, comes to fix it, independent of strong causes, either favouring or preventing repletion; e.g. blood-letting will not impede it, nor filling the body induce it: and, indeed, so much is this evacuation connected with periodical motions, that it is little in our power to produce any effect by medicines but at those particular times. Thus, if we would relax the uterine system, and bring back this evacuation when suppressed, our attempts would be vain and fruitless, unless given at that time when the menses should have naturally returned.

CUSTRIN, a handsome town of Germany, in the New Marche of Brandenburg, with a castle. It is situated in a morass, surrounded by two branches of the Oder, 46 miles E. by N. of Berlin. Long. 14. 40. E. Lat. 52. 40. N.

CUTAIS, the capital of Imeritia, a country between the Black Sea and the Caspian, and the residence of its sovereign prince David. The remains of its cathedral seem to prove that it was once a considerable place, but it now scarcely deserves the name of a village.

CUTCH, a territory of considerable extent in Hindoostan Proper. It is governed by a rajah of its own, and is situated

on the S. E. of Sindy; the E. branch of the Indus separating the two countries. It extends along the N. coast of the gulf of Cutch, and is separated from Guzerat by the river Puddar, or one of its branches. It abounds with hills, woods, and sandy wilds. The interior part of it is unknown. Its capital is Boodee-boodee.

CUXHAVEN, a sea-port of Bremen, situated on the German Ocean, between the mouths of the Elbe and the Weiser.

CYCLOID (*Encycl.*). On the subject of cycloidal curves, a French writer has the following remark: "Il semble qu'une destinée particulière attachée à la cycloïde, lui donne préférablement aux autres courbes un plus grand nombre de propriétés remarquables."

Definition I.

When a circle is made to rotate on a rectilinear basis, the figure described on the plane of the basis by any point in the plane of the circle is called a trochoid. A circle concentric with the generating circle, and passing through the describing point, may be called the describing circle.

Definition II.

If the describing point is in the circumference of the rotating circle, the two circles coincide, and the curve is called a cycloid.

Definition III.

If a circular basis be substituted for a rectilinear one, the trochoid will become an epitrochoid, and the cycloid an epicycloid.

Scholium 1. The terms have hitherto been too promiscuously employed; the terms cycloid and trochoid have been used indifferently; and the term epicycloid has comprehended the epitrochoid, the terms prolate and contracted being sometimes added to imply that the describing point is within or without the generating circle. The interior epicycloid and epitrochoid may very properly be distinguished by the names hypocycloid and hypotrochoid, whenever they are the separate objects of consideration. The different species of epicycloids may be denominated according to the number of their cusps, combined with that of the entire revolutions which they comprehend; for instance, the epicycloid described by a circle on an equal basis is a simple unicuspate epicycloid; and if the diameter of the generating circle be to that of the basis as 5 to 2, the figure will be a quintuple bicuspate epicycloid. If the describing circle of a trochoid or cycloid be so placed as to touch the middle of the basis, and each of the ordinates parallel to the basis be diminished by the corresponding ordinate of the circle, the curve thus generated has been denominated the companion of the trochoid, the figure of the lines, and the harmonic curve.

Scholium 2. The invention of the cycloid has been attributed by Wallis, Ph. Tr. for 1697, n. 229, to Cardinal Cusanus, who wrote about the year 1450: but it seems to be at least as probable that the curve which appears in Cusanus's figure was meant for the femicircle employed in finding a mean proportional. Bovillus, in 1501, has a juster claim to the merit of the invention of the cycloid and trochoid, if it can be any merit to have merely imagined such curves to exist. In 1599, Galileo gave a name to the common cycloid, and attempted its quadrature, but having been accidentally misled by repeated experiments on the weight of a flat substance cut into a cycloidal form, he fancied that the area bore an incommensurable ratio to that of the circle, and desisted from the investigation. Mericenus described the cycloid, in 1615, under the name of la trochoïde, or la roulette, but he went no further. Roberval seems to have first discovered the comparative quadrature and rectification of the cycloid, and the content of a cycloidal solid, about the year 1635, but his treatise

was not printed until 1695. Torricelli, in 1644, first published the quadrature and the method of drawing a tangent. Wallis gave, in 1670, a perfect quadrature of a portion of the cycloid. The epicycloid is said to have been invented by Ræmer; its rectification and evolute were investigated by Newton in the Principia, published in 1687. In 1695 Mr. Caswell shewed the perfect quadrability of a portion of the epicycloid, and Dr. Halley immediately published an extension of Caswell's discovery, together with a comparison of all epitrochoidal with circular areas. M. Varignon is also said to have reduced the rectification of the epitrochoid to that of the ellipsis, in the same year. Nicole, Delahire, Pascal, Reaumur, Maclaurin, the Bernoullis, the commentators on Newton, and many others, have contributed to the examination of cycloidal curves, both in planes and in curved surfaces; and Waring, the most profound of modern algebraists, has considerably extended his researches upon the nature of those lines which are generated by a rotatory progression of other curves. In the present day the most remarkable properties of cycloidal curves are deduced in a simpler and more general manner than appears to have been hitherto done, the equations of several species are investigated, a singular property of the quadricuspidate hypocycloid is demonstrated, and the peculiarities of the spiral of Archimedes are derived from its generation as an epitrochoid.

PROPOSITION I. THEOREM. PL. 23. FIG. 1.

In any curve generated by the rotation of another on any basis, the right line joining the describing point, and the point of contact of the generating curve and the basis, is always perpendicular to the curve described.

It may by some be deemed sufficient to consider the generating curve as a rectilinear polygon of an infinite number of sides; since, in this point of view, the proposition requires no further demonstration; and, indeed, Newton and others have not scrupled to take it for granted: but it is presumed that a more rigid proof will not be considered as superfluous. Let M be the describing point, and P the point of contact; and let LO, MP, and NQ, be successive positions of the same chord of the generating curve at infinitely small distances; then it is obvious, and easily demonstrable, that the arcs OP and PQ, described by the point P of the generating curve in its passage from O to P, and from P to Q, will be perpendicular to the basis at P, and will therefore touch each other. Let the arcs L, IMK, and N, be described with the radius PM, on the centres O, P, and Q. Then the curve described by M will touch IMK; for since O and Q lie ultimately in the same direction from P, if L be above IMK, N will also be above it, since these points must be in the circles L and N, and infinitely near to M; and if L is below IMK, N, for the same reason, must be below it; and M is common to the circle and the curve, therefore the curve touches the circle IMK at M, and is perpendicular to the radius PM.

PROPOSITION II. PROBLEM.

To draw a tangent to a cycloidal curve at any given point.

On the given point as a centre describe a circle equal to the describing circle of the curve, and from the intersection of this circle, with the line described by the centre of the generating circle, let fall a perpendicular on the basis; the point thus found will be the point of contact, and the tangent will be perpendicular to the right line joining this point of contact and the given point, by the first proposition. It will be obvious, from inspection, which of the two intersections of the circle to be described, with the tract of the centre, is to be taken as the place of that centre corresponding to the given point.

PROPOSITION III. PROBLEM. FIG. 2.

To find the length of an epitrochoid.

Let C be the centre of the basis VP, K that of the rotating circle PR, and of the describing circle GL, P the point of con-

tact, and M the describing point. Then joining MNC, and supposing VX to be an element representing the motion of the point P in either the basis or the generating circle, draw the arc MN on the centre C, and join CVN, then NM will represent the motion of the point M as far as it is produced by the revolution round the centre C: take MO to VX as GK to PK, then MO will be the motion of M arising from the revolution round K, and NO will be the element of the curve produced by the joint motion. Let CH be parallel to PM, then CX or CP : CM :: VX : MN, and PK : MK :: CP : HM :: VX : MO, therefore CM : HM :: MN : MO, and these lines being perpendicular to CM, HM, the triangle NMO is similar to CMH, and MN : NO :: CM : CH, hence CP : CH :: VX : NO. Take PY to CP as PK to CK, then CH : CP :: PM : PY :: NO : VX. On L describe the circle PFB, and draw IMLF : let FD be perpendicular to PRB, take DE to DF as PL, and E will be always in the ellipsis BEP : let AE and AF be tangents to the ellipsis and circle at E and F; then the increment of the arc EF will be to MO as PL to GL, and to VX as PL to PR. Join GM, and parallel to it draw PI; then PIL is a right angle, and ILP = AED, and IM : IL :: PG : PL :: DE : DF, by construction; therefore the figure IMLP is similar to DAEF, as PL to PM so is AF to AE, and so is the increment of the arc BF to that of BE; but the increment of BF is to VX as PL to PR, therefore the increment of BE is to VX as PM to PR. Now, it was proved that NO : VX :: PM : PY; therefore the increment of BE is to NO as PY to PR, or as CP to 2 CK: and the whole elliptic arc BE is to the whole SM as the radius of the basis to twice the distance of the centres.

Corollary 1. The fluxion of every cycloidal arc is proportional to the distance of the describing point from the point of contact.

Corollary 2. In the epicycloid the ellipsis coincides with its axis BB, and the arc BE with BD, which is double the versed sine of half the arc GM, in the describing or generating circle: therefore the length of the curve is to this versed sine as four times the distance of the centres to the radius of the basis.

PROPOSITION IV. PROBLEM. FIG. 2, 3.

To find the centre of curvature of an epitrochoid.

Let PY be, as in the last proposition, to CP as PK to CK, and on the diameter PY describe the circle PZY, cutting PO in Z: take OW a third proportional to OZ and OP, and W will be the centre of curvature. For, let QP = VX be the space described by P, while NO is described by O; it is obvious from prop. 1, that the intersection of NQ and OP must be the centre of curvature. Let QT be perpendicular to PA parallel to QN; then, by prop. 3, NO : VX or QP :: PO : PY, but by similar triangles QP : CF :: PY : PZ; therefore NO : QR :: PO : PZ, and by division, NO : ΔO :: OP : OZ; and by similar triangles :: OW : OF or OF.

Corollary. When Z coincides with O or M, OW is infinite; therefore whenever PZY intersects the describing circle, the epitrochoid will have a point of contrary flexure at the same distance from C as this intersection: and the circle PZY is given when the basis and generating circle are given, whatever the magnitude of the describing circle may be.

PROPOSITION V. PROBLEM. FIG. 4.

To find the evolute of an epicycloid.

In the epicycloid SM, the point M being in the circumference of PMR, PZ will be to PM in the constant ratio of PY to PR, and MZ to PM as RY to PR; and PM to MW in the same ratio; hence PM : PW :: RY : PY :: CR : CP, therefore the point W is always in a circle PWΞ of which the radius is to PK in that proportion and which touches SP in P. On the centre C describe a circle ΔΞΘ touching PWΞ in Ξ; then, since CR : CP :: PR : PΞ, we

have by division CR : CP :: CP : PΞ, and the circle PWΞ being to ΔΞΘ as PMR to SP, the arc PM being equal to SP, the similar arc PW will be equal to ΔΞ, and, taking ΔΞΘ = PWΞ, ΞΘ will be always equal to ΞW, and W in a curve ΘWS similar to SM, of which it is the evolute.

PROPOSITION VI. PROBLEM. FIG. 5.

To find the area of an epitrochoid.

On the centre C describe a circle touching the epitrochoid in S, take GN to GC as PR to PC, and let the circle GΘΠ describe on the basis SG the epicycloid SΘ. Then taking GM always to GΘ as GL to GN, M will be in the epitrochoid SM; for the angular motion of the chord GΘ, is the same as that of GM in the primary epitrochoid. Let SΩ be the evolute of SΘ, and GWΞ its generating circle. On diameters equal to ΞG, ΞL, and ΞΠ, describe three circles, AD, AE, and AF, touching the right line AB in A; let the angle BAD be always equal to GΘΦ, and it is evident that AD, AE, and AF, will be equal respectively to WG, WM, and WΘ. But the angular motion of WG on W being equal to the sum of the angular motions of GM on G and CG on C, is to that of AF, or of GM, or half that of KM, in the ratio of CN to CG, or CR to CP; therefore the fluxions of the areas SWG, SWM, and SWΘ are to those of the segments AD, AE, and AF, in the same ratio; and that ratio being constant, the whole areas, and their differences, are also respectively to each other as CR to CP.

Scholium. The quadrable spaces of Halley are those which are comprehended between the arc of the epitrochoid, that of the describing circle, and that of a circle concentric with the basis and cutting the describing circle at the extremities of its diameter.

PROPOSITION VII. PROBLEM. FIG. 6.

To find a central equation for the epicycloid.

Let CT be perpendicular to RT, the tangent at the point M, then PMR will be a right angle, and PM parallel to CT. On the centre C describe through M the circle MNO, and let MQ be perpendicular to RO. Then the rectangle OQN = PQR, OQ : PQ :: QR : QN, by addition OQ : PQ :: OR : PN; hence by division OP : PQ :: IR : PN, and PQ = $\frac{OPN \text{ or } INP}{IR}$. But PMQ = PR × PQ =

$\frac{PR}{IR} \times INP$; and by similar triangles CT : CR :: PM : PR, whence CTQ = $\frac{CRq}{PRq} \times PMq = CRq \times \frac{INP}{IRP}$. Let MZ and RY be tangents to SP, then INP = MZ, and IRP = RY, CT = CR × $\frac{MZ}{RY}$, and CT will be to MZ in the constant ratio of CR to RY. Putting CP = a, CR = b, CM = s, CT = u, then $uu = \frac{bs - aa}{bb - aa}$.

PROPOSITION VIII. PROBLEM. FIG. 7.

To find a geometrical equation for the conchoidal epitrochoid.

Let CP = PK. On the centre C describe a circle equal to GM, cutting SC in Z. Join MZF, then the arc DZ = GM, and GM is parallel to CK, therefore BF is also equal to DZ or GM, CF is parallel to KM, and MF = CK: therefore this epitrochoid is the curve named by Delahire the conchoid of a circular basis, as was first observed by Reaumur in 1708, and afterwards by Maclaurin, in 1720. Call CK, a, DE, b, ZH, x, HM, y, ZM, s, and let ZI be perpendicular to CK; then FZ = a - s, CI = $\frac{a-s}{2}$, and, CIZ and ZHM being similar, CZ : CI :: ZM : ZH,

or $\frac{b}{2} : \frac{a-s}{2} :: s : x$; hence $bx = as - ss$, $bx + ss = as$,

$L^2x^2 + 2bsx^2 + s^4 = a^2x^2$, and by substituting for s^2 , $x^2 + 2bx^2 - a^2x^2 + b^2x^2 + 2x^2y^2 + 2bxy^2 + y^4 - a^2y^2 = 0$.

Corollary 1. Join FN, and complete the parallelogram MPNL, then since EF = DZ = EN, FN is perpendicular to EK, and ML to NL, and, NL being always equal to FM or CK, L is always in a circle described on the centre N, LM a tangent to that circle, and ZM a perpendicular to that tangent drawn from the point Z.

Corollary 2. Fig. 8. The unicuspitate epicycloid admits of a peculiar central equation, with respect to the point S. Call SM, s , and let ST = u be perpendicular to the tangent

MT, then $u = \frac{s^2}{2a}$. For the triangles SIP and MTS being

similar, and IP being half of SM, or s , SP = $\sqrt{\frac{as}{2}}$, SPq :

SMq :: IPq : STq, or $\frac{as}{2} : s^2 :: \frac{ss}{4} : u^2$, and $2au^2 = s^3$.

Corollary 3. Fig. 8. The unicuspitate epicycloid is one of the caustics of a circle. For making the angle CRY = MRC = $\frac{1}{2}$ SCP, the triangle CRY is isosceles, and CY is constant; so that all rays in the direction of the tangent MR will be reflected by the circle QR towards Y, and consequently SM will be the caustic of a radiant point at Y.

PROPOSITION IX. PROBLEM. FIG. 9.

To find a geometrical equation for the tricuspitate hypocycloid.

Let PA and MF be perpendicular to CS. Join PMB, KM, RMG, and PD. Then the angle APB is equal to the difference of APC and MPB, or to that of their complements PRM, PCA : but PRM = $\frac{1}{2}$ PKM = $\frac{1}{2}$ PCA, therefore APB = $\frac{1}{2}$ PCA = ADP = APS, and the triangles APS and APB are similar and equal. Let SC = a , SF = x , FM = y , and SB = r . Then SA : SP :: SP : SD, and SP = $\sqrt{ar}$. Draw PE perpendicular to BP; then BE = SD = $2a$, BC = $a - r$, EC = $3a - r$, and by similar triangles, CP : CR :: EC : CG = $\frac{1}{2}$ EC = $a - \frac{1}{2}r$; therefore GB = $\frac{3}{2}r$; but BE : BG :: BP : BM, or $2a : \frac{3}{2}r ::$

$\sqrt{ar} : \frac{r}{3a} \sqrt{ar} = BM$; again, BP : BM :: BA : BF, or

$\sqrt{ar} : \frac{r}{3a} \sqrt{ar} :: \frac{r}{2} : \frac{rr}{6a}$, and SF = x , $r = r - \frac{rr}{6a}$, $6ax =$

$6ar - rr$, and $r = 3a \pm \sqrt{9aa - 6ar}$. But MFq = BMq

= BFq, or $y^2 = \frac{r^2}{9a} - \frac{r^4}{36a^2}$, and $36a^2y^2 = 4ar^3 - r^4$. By adding to this the square of the former equation, and proceeding in the same manner to exterminate r , we obtain an equation of the value of x and y , which, when the surds are brought to the same side, and the square of the whole is taken, is at last reduced to $x^4 - \frac{4}{3}ax^3 + 2x^2y^2 - 12axy^2 + y^4 + 12a^2y^2 = 0$, a regular equation of the fourth order.

Scholium. The equation of the corresponding hypotrochoids may be investigated nearly in the same manner, by dividing PR and PM in a given ratio, but the process will be somewhat more tedious.

PROPOSITION X. PROBLEM. FIG. 10.

To find a geometrical equation for the bicuspitate epicycloid.

Let CP = PR. Join RMS, PM, PD; draw CT perpendicular to RT, TE to CR, and EG, MB, RA, to SC. Then the angle DRP = $\frac{1}{2}$ MKP = SCP, and by equal triangles; RA = CT, and RD = CD, and by similar trian-

gles RM : RP :: RE : RT, and RP : RD :: RT : RC : therefore RM : RD :: RE : RC, and ME is parallel to SC, and EG = BM. Put CP = a , BC = x , BM = y , CM = s , CT = u ; then by prop. 7. $u^2 = \frac{4}{3}s^2 - a^2$; or $\frac{4}{3}u^2 = s^2 - a^2$; but RC : CT :: CT : CE :: CE : EG, or y ,

hence $y = \frac{u^3}{4aa} = \frac{16a^2y^3}{64}$, $\frac{27}{64}u^6 = \frac{27}{4}ay^2 = \frac{ss - aa^2}{4}$

= $\frac{xx + yy - aa^2}{4}$; whence by involution the equation of the sixth order may be had at length.

Corollary. Since CRM = SCR, a ray in the direction of the tangent MR will be reflected by a circle FR always parallel to SC : therefore SM is the caustic of the circle FR when the incident rays are parallel to CS.

PROPOSITION XI. PROBLEM. FIG. 11.

To find a geometrical equation for the quadricuspitate hypocycloid.

Let CR = PR, then the angle PRM = $\frac{1}{2}$ PKM = 2 PCS, RAC = ACR, RA = RC = RB = RP, AB = SC, and drawing the perpendiculars CT, TD, TE, and MF, RM = RT, AM = BT, AF = EC, FC = AF, and FM = BD. Let SC = a , FC = x , FM = y , CM = s , CT = u ; then AB : AC :: AC : AT :: AT : AE, whence AT = $\frac{ax^2}{ax^2}$, and in the same manner BT = $\frac{ay^2}{ay^2}$; and CT being a mean proportional between AT and TB, $u^2 = \frac{a^2x^2y^2}{a^2x^2y^2}$, and $u^6 = a^2x^2y^2$. But by prop. 7. $3u^2 = a^2 - s^2$, therefore $27a^2x^2y^2 = a^2 - s^2 = a^2 - x^2 = y^2$; whence the equation may be had at length by involution. The same result may be obtained by Dr. Waring's method of reduction, from

$\frac{axx}{axx} + \frac{ayy}{ayy} = a$.

Corollary. Since the portion of the tangent AB intercepted between the perpendiculars AC, BC, is a constant quantity, this hypocycloid may in that sense be called an equitangential curve; and the rectangular corner of a page-fate must be rounded off into the form of this curve in order to admit a beam of a given length to be carried round it.

PROPOSITION XII. PROBLEM.

To investigate those cases in which the general propositions either fail or require peculiar modifications.

Case 1. Fig. 12. If the generating circle be considered as infinitely small, or the basis as infinitely large, so as to become a straight line, the epicycloid will become a common cycloid, and the ratio of CP to CK in prop. 3. cor. 2. becoming that of equality, the length of the arc SM will be four times the versed sine of half PM, and VM twice the chord RM or VX, therefore the square of the arc VM is always as the absciss VZ. The evolute is an equal cycloid, and the circles in prop. 6. being as 1 to 4, the area of the cycloid is to that of its generating circle as 3 to 1. The properties of the cycloid as an isochronous and as a brachistochronous curve belong to mechanics, and it is demonstrated by writers on optics that its caustic is composed of two cycloids.

Case 2. Fig. 13. If the generating circle be supposed to become infinite while the base remains finite, the epicycloid will become the involute of a circle; and the fluxion of the curve being always, by prop. 3. cor. 1. to that of PM as PM to CP, its length SM will be a third proportional to IP and PM. Call CP, a , and PM, x , then the fluxion of SM is

$\frac{xx}{a}$; but the rectangle contained by half PM and the fluxion

of SM is the fluxion of the area PSM, or FPM = $\int \frac{xx}{2a} dx = \frac{x^3}{6a}$. The epitrochoid described by the point C of the gene-

Cycloid Curve.

rating plane will be the spiral of Archimedes, since CN is always equal to PM = PS = QV; and since the angular motion of CN and PM are also equal, the area CON = PSM = $\frac{\pi^2}{6a}$. Instead of the ellipsis of prop. 3, let PX be a parabola

of which IP is the parameter, and continuing NM to X, the arc PX will be equal to CON. For making LQ = CP, it is well known that the fluxion of PX varies as XQ or as PN, which represents the fluxion of CON. For the curvature, PY in prop. 4, becomes = CP, and the radius is a third proportional to NZ and NP.

Case 3. Supposing now the generating circle to become again finite, but to have its concavity turned towards the basis, the same curve will be described as would be described by the rotation of a third circle on the same basis in a contrary direction, equal in diameter to the difference of those of the two first circles.

Case 4. If the circles be of the same size, with their concavities turned the same way, no curve can be described; but if the generating circle be still further lessened, a hypocycloid will be produced, if the same figure as that which would be described by a third circle equal in diameter to the difference of the two first. All the general propositions are equally applicable to hypocycloids with other epicycloids, as might easily have been understood from an inspection of the figures, if there had been room for a double series.

Case 5. Fig. 14. If the diameter of the generating circle be half that of the basis, the hypocycloid will become a right line, and the hypotrochoid an ellipsis. For since the angle PKM = 2 PCS, PCM, being half PKM, coincides with PCS, and M is always in CS. Let GNL be the describing circle of the hypotrochoid, and join GNO, then NL is parallel, and ON perpendicular to SC and ON = HL, which is always to GO as CL to CG; therefore AN is an ellipsis: and the centre C will evidently describe a circle.

CYRIL (St.) bishop of Jerusalem, succeeded Maximus in 350. He was afterward deposed for the crime of exposing to sale the treasures of the church, and applying the money to the support of the poor during a great famine. Under Julian he was restored to his see, and was firmly established in all his old honours and dignities under Theodosius; in which he continued unmolested to his death in 386. The remains of this father consist only of 23 catecheses, and one letter to the Emperor Constantius.

CYRILL (St.), patriarch of Alexandria, succeeded Theophilus, his uncle, in 412. Scarce was he installed, when he began to exert his authority with great vigour; he drove the Novatians and Jews from Alexandria, permitting their wealth and synagogues to be taken from them. This proceeding highly displeased Orestes, the governor of the city, who saw that if the bishop's authority was not soon suppressed it might grow too strong for that of the magistrate. Upon which a kind of civil war broke out between Orestes and the bishop; many tumults were raised, and some battles fought in the very streets of Alexandria. St. Cyrill also distinguished himself by his zeal against Nestorius bishop of Constantinople, who, in some of his homilies, had asserted that the Virgin Mary ought not to be called the mother of God. The dispute at first proved unfavourable to Cyrill, whose opinion was not only condemned, but himself deprived of his bishopric and thrown into prison. But he was soon after released, and gained a complete victory over Nestorius, who in 431 was deposed from his see of Constantinople. Cyrill returned to his see at Constantinople, where he died in 444. St. Cyrill also wrote against Theodorus of Mopsuestia, Diodorus of Tarsus, and Julian the apostate. He composed commentaries on St. John's gospel, and wrote several other books. His works

were published in Greek and Latin in 1638, in six volumes folio.

CYRILL LUCAR, patriarch of Constantinople. This eminent man, who has been strangely neglected by the writers of biographical collections, was born in the isle of Candia at the time when it was under the protection of the Venetians. He received his education at Venice under Maximus Margunius, afterwards bishop of Cerigo (an island in the entrance of the Archipelago), who wrote in Greek a learned discourse concerning the procession of the Holy Ghost. After he had finished his studies there, and had acquired a perfect knowledge of the Latin and Italian languages, he travelled into various parts of Europe, the better to fit himself for the service of his country. On his return into the East he was made a priest, and afterwards archimandrite, or prior of a convent. In 1600 he was made the bearer of a letter from Meletius patriarch of Alexandria, to Sigismund III. king of Poland and Sweden; the occasion of which was this: several bishops of Lithuania and Black Russia who had hitherto continued in the communion of the Greek church, wrought upon by several temporal advantages, which they proposed to gain in the diet of Poland, sent two of their number to Rome to make their submission to the pope in 1595. This gave great offence to the other members of the Greek church, but the design of an union being favoured by the king, a synod was called at Brest, to establish this affair. At this synod the Duke of Ostrovia and those of the Greek party appeared, and firmly refused to submit to the proposed union. The name of *non-unia*, or *dissenters*, was given to those persons who resolved to adhere to the Greek church, and in obedience to the Patriarch of Constantinople. Cyril was one of these, being sent thither for the express purpose of breaking off the union of the Russians with the church of Rome. Afterwards this party had several conferences with the Protestant noblemen and divines, particularly those of the Lutheran communion; and some steps were taken to effect an union between the Protestant and Greek churches. But this excellent design proved abortive. About this time Sigismund, out of his zeal for the Roman church, published an edict against the spreading of the Greek religion in his dominions; and soon after wrote a treatise to Meletius, advising him to make his submission to the pope. This letter he answered with all due respect, desiring him to bestow his favour upon Cyril, the bearer, as being worthy of it, both for his learning and integrity. His active way of life, and knowledge of the world, gained by his travels and employments, rendered him every-where conspicuous and deserving in the esteem of all of the highest dignity of his church. The patriarchal see of Alexandria becoming vacant, he was chosen to succeed Meletius, and in that seat he continued nineteen years. The great deference which the other patriarchs of the Greek communion pay to the see of Constantinople induces them to make frequent journeys thither. Here Cyril came about the beginning of 1612; and in the lent following a priest of that church, who had received part of his education among the Jesuits, said many things in favour of the Romish religion, which occasioned Cyril to oppose him with the greatest earnestness. While he was at Constantinople the patriarch of that see died; a circumstance which usually produces considerable confusion, as the rest of the bishops make use of all kinds of means to get the election. The Turks take advantage of these dissensions; and as the patriarch must be confirmed by the grand-seignior, the visier and bashas expect considerable bribes from all the candidates. Cyril had a great party among the bishops, who wished him to be advanced to the patriarchate for the good of the Greek church. To prevent his being elected, the opposite party made use of the accustomed mode;

and by advancing a large sum, got Timothy bishop of Marmara appointed; but he died soon after, and Cyril was chosen without opposition to the vacant chair in 1621. This appointment was very mortifying to the Jesuits, and other zealous members of the Roman communion, because they knew how great an enemy he was to their corruptions; how well inclined to a reformation, and particularly favourable to the Protestant churches. Every artifice, therefore, was adopted to effect his ruin; and, by the help of the French ambassador, they were in hopes to get him deposed, in order that Gregory bishop of Anagla, a creature of their own, might occupy his place. Cyril instantly called a synod, in which the ambitious pretender was excommunicated. The enemies of the patriarch, however, succeeded in prejudicing the mind of the visier against him, and he was banished to Rhodes; after which Gregory was advanced to the patriarchal dignity, on a promise of paying twenty thousand dollars, but not being able to raise this sum, Anthimus archbishop of Adrianople purchased the place. This gave great satisfaction to the court of Rome, and Pope Urban VIII. complimented the French ambassador on his skill and dexterity in this infamous business. But this triumph did not last long, for the English ambassador, Sir Thomas Rowe, interposed so effectually, that Cyril was recalled to Constantinople, and Anthimus made his submissions to him and received absolution. New designs were then formed, and the pope sent over an anti-patriarch, under the title of Apostolical Suffragan, enjoining full power to do what was necessary to promote the interests of the Roman church. Accordingly several titular bishops were created of Smyrna, Naxia, and other places. The Greeks, alarmed at this attempt upon their church, made heavy complaints to the visier, and with such success, that the suffragan was glad to escape for his life, and the titular bishops were thrown into prison. Matters seemed now to wear a favourable aspect; but the calm was of short duration, for Cyril's enemies were only watching an opportunity to complete their grand object. In 1627 a Greek priest, called Mataxa, who had resided in England several years, and had learnt there the art of printing, arrived at Constantinople, and brought with him a printing press and types for the use and information of the poor Greeks. The design was excellent; but it was difficult to get the luggage ashore without giving jealousy to the Turks. The priest was brought to Sir Thomas Rowe by the Archbishop of Corinth, from the patriarch, to beg of him to own the goods, which accordingly he did. The ambassador, however, would not permit the press to be worked in his house, but advised them to take one in the neighbourhood for the purpose. When the Jesuits heard that this press was set up, they were greatly alarmed, and were determined to put an end to the work, which they knew to be unfavourable to their cause. They insinuated that the patriarch intended to subvert the faith of his own church, on which he caused a small book to be printed concerning the doctrine of that church, dedicated to Charles I. king of England. This gave them additional offence; but as they could gather nothing from this book on which to ground an accusation, they had recourse to another which he had written and got printed in England, in defence of the divinity of Christ against the Jews. Having gathered some passages from this treatise which opposed the Koran, they laid them before the visier, at the same time charging Cyril with the design of stirring up the Cossacks to invade the empire. The visier, without any further enquiry, sent his soldiers to the printing-house, and took possession of its contents; but Mataxa escaped. The English ambassador, on this, waited upon the visier, and expostulated with him so effectually, that he was convinced of having been imposed upon, and promised to restore all the goods within three days,

And as the Jesuits had taken great liberties with the name of Sir Thomas, by representing him as the head of the heretics, and a friend of seditious persons, satisfaction was made to him, by sending the accusers to prison, where they would have suffered by the bow-string, if he had not interceded for their lives. The patriarch now enjoyed repose for a considerable time; though his enemies still fostered their virulent animosity against him, and promoted dissensions among his bishops, in order to effect, at last, his deprivation. In 1630, a Confession of Faith, drawn up by Cyril, was printed in Latin at Geneva, and occasioned considerable observation, and some controversy. The Romanists, nettled at a work which flatly opposed the dogmata of their church, and the pretensions of their pontiff, caused an answer to be made to it in Greek, and dispersed over the East. Soon after this the French ambassador at Constantinople gave a dinner to the patriarch and his friends; after which he shewed him the Confession which had been sent to him by order of the pope, with express orders to demand of him if he was the real author of it, and maintained the doctrines therein contained. Cyril honestly replied, that it undoubtedly was his Confession; but that as he owed no obedience to the pope, he was not obliged to render him any account of his faith; adding besides, that he stood at the head of a church to which he would be always ready to give satisfaction in a general synod, referring all to the Word of God, and the fathers of the primitive church. To this the ambassador replied, that at Rome, and in France, they looked upon him as a Calvinist, which sect was much hated by the king, his master, who, therefore, wished that the patriarch would become a Roman-catholic. The answer of this good man was in these words: "In the articles of my belief, and my eternal salvation, I shall neither follow the king of France nor the pope of Rome; neither will I act contrary to the dictates of my own conscience." In 1634 his enemies got him banished to the isle of Tenedos, and Anastasius was elected in his room; but, in a few months, he was restored to his seat, though not without a heavy contribution being paid to the grand-seignior. The year following another competitor was set up; the patriarch was sent to the isle of Rhodes; and so eager were his adversaries to destroy him utterly, that a design was formed to take him off the island, and carry him to Italy, where, doubtless, he would have been made a sacrifice of by the inquisition. This design being discovered, the governor of the island removed him from thence, and thus prevented the scheme from being carried into effect. In July, 1636, he was restored again, and the visier being his friend, he rested safely for some time; but, in 1638, Bairam Basha becoming the favourite of the sultan, represented Cyril as a dangerous man, by whose instigation the Cossacks had lately committed some depredations on the frontiers; and that, by his influence over the people of his persuasion, he might probably stir them up to mutiny. The emperor on this sent an order for his being strangled immediately. The governor of Constantinople, on receiving this mandate, sent his officers to seize on the patriarch, and sent him prisoner to a castle on the Bosphorus. From thence he was conveyed into a boat, where the fatal bow-string being applied to his neck, he was soon dispatched; they then stripped the body and threw it into the sea, from whence it was afterwards taken by some fishermen, and by some of his friends buried on the shore. When this was made known to the government, an order came for taking the body up, and throwing it again into the sea, which was done; but the body was afterwards recovered, and buried obscurely in one of the small islands that lie over against the bay of Nicomedia.

He was, in all respects, a great man, and may justly be termed a martyr for truth and religion, having been persecuted

by his enemies all through his public life, for firmly resisting the encroachments of a foreign power, and strenuously supporting the independence and faith of his own church.

He had a great regard for the English church and nation, which, about the same time, was suffering violently from the attacks of restless and ambitious men. He sent over to King Charles I. that famous Alexandrian MS. of the New Testa-

ment which is now in the king's library, and has been edited in a capital manner by the late learned Dr. Woide.

CZERCASSI, a town of Russia, in the Ukraine, with a castle, seated near the Dnieper, 85 miles SE. of Kiow. Long. 32. 1. E. Lat. 49. 0. N.

CZERSKO, a town of Poland, on the Vistula, twenty miles N.W. of Warsaw. Long. 21. 31. E. Lat. 52. 26. N.

D

DAM

DACHSBACH, a town of Franconia, 22 miles S. of Bamberg.

DACHSTEIN, a town of France in the department of Lower Rhine, with a palace that belonged to the see of Strasbourg. Long. 7. 45. E. Lat. 48. 35. N.

DACHSTUHL, a town of Germany, in the circle of Upper Rhine, and principal place of a lordship, which gives the possessor a seat and voice at the diets of the circles, though not at that of the empire. It is 22 miles S.E. of Treves.

DADO, in architecture and joinery, a word which has three different meanings, 1st. It denotes the cubic part of the pedestal of a column or statue, included between the base and the entablement. 2d. That part of the pedestal of a pilaster, which corresponds with the *dado* in solid work. 3dly. It means that part of the wainscoting, or stucco work, which is a lateral prolongation of the *dado* of a pilaster; *i. e.* the place included between the foot-board and the cornice of the wainscoting.

DAFAR, or DOPAR, a town of Arabia Felix, seated on a bay of the same name, on the S.E. coast. Long. 53. 25. E. Lat. 16. 30. N.

DAGISTAN, or DAGHESTAN, a town of Persia, capital of the province of Daghestan; situate on a river, which runs into the Caspian Sea, 240 miles N.W. of Meshid.

DAHL, the finest river of Sweden, which flows through Dalecarlia and on the S. confines of Geftricia, and falls into the gulf of Bothnia, to the E. of Geste. Near Escarleyb, it forms a celebrated cataract, scarce inferior to the fall of the Rhine at Laufen.

DAILLIE (John), a Protestant minister near Paris, was one of the most learned divines of the 17th century, and was the most esteemed by the Catholics, of all the controversial writers among the Protestants. He was tutor to two of the grandsons of the illustrious Mr. Du Pleffis Mornai. Mr. Dailie having lived fourteen years with so excellent a master, travelled into Italy with his two pupils: one of them died abroad; with the other he saw Italy, Switzerland, Germany, Flanders, Holland, and England, and returned in 1621. He was received minister in 1623, and first exercised his office in the family of Mr. Du Pleffis Mornai; but this did not last long, for that great lord died soon after. The memoirs of this great man employed Mr. Dailie the following year. In 1625 he was appointed minister of the church of Saumur, and in 1626 removed to Paris. He passed all the rest of his life in the service of this last church, and composed several works: his first piece was his master-piece, and an excellent work, *Of the Use of the Fathers*, printed in 1631. It is a strong chain of reasoning, which forms a moral demonstration against those who would have religious disputes decided by the authority of the fathers. He died in 1670, aged 77.

DAM, a town of the United Provinces, in Groningen,

DAN

seated on the Damster, three miles from the sea, and fifteen S.W. of Embden. Long. 6. 48. E. Lat. 53. 22. N.

DAM, a town of Prussian Pomerania, seated on the Oder, ten miles S.E. of Stetin. Long. 14. 50. E. Lat. 53. 31. N.

DAMANHOUR, a town of Egypt, near the canal of Alexandria; 32 miles S.E. of Alexandria.

DAMAR, a town of Arabia Felix, in Yemen, 100 miles S. of Sanaa. Long. 46. 33. E. Lat. 16. 0. N.

DAMASCENUS (John), an illustrious father of the church in the 8th century, born at Damascus, where his father, though a Christian, enjoyed the office of counsellor of state to the Saracen caliph; to which the son succeeded. He retired afterwards to the monastery of St. Sabas, and spent the remainder of his life in writing books of divinity. His works have been often printed; but the Paris edition in 1712, two volumes folio, is esteemed the best.

DAMASCIUS, a celebrated heathen philosopher, born at Damascus in the year 540, when the Goths reigned in Italy. He wrote the *Life* of his master Iddorus; and dedicated it to Theodora, a very learned and philosophical lady, who had also been a pupil to Iddorus. In this *Life*, which was copiously written, he frequently made oblique attacks on the Christian religion. We have nothing remaining of it but some extracts preserved by Photius. Damascius succeeded Theon in the rhetorical school, and Iddorus in that of philosophy, at Athens.

DAMGARTIN, a town of Swedish Pomerania, with a castle, seated on the Recknils, eighteen miles W. of Stralfund. Long. 12. 57. E. Lat. 54. 16. N.

DAMM, a town of Upper Saxony, in the duchy of Pomerania. The inhabitants carry on a considerable trade in steel manufactures. It is seated on the Plohe, five miles E. of Stetin. Long. 14. 39. E. Lat. 53. 21. N.

DAMME, a strong town of Flanders, seated on the canal between Shys and Bruges. It was taken by the duke of Marlborough in 1706, and ceded to the Dutch at the peace of Utrecht.

DAMME, a town of the United Provinces, in Groningen. Though unfortified, it enjoys the privileges of a city, and before the late revolution had a voice among the states of Groningen. It suffered much by inundations some years since. It is seated on the Damster, fourteen miles N.E. of Groningen.

DANBURY, a village in Essex, situate on a hill, five miles E. of Clemsford, and sixteen W. of the sea. The spire of the church was burnt by lightning in 1750, but was soon after rebuilt, and forms a sea-mark.

DANCALI, or DANKALI, a kingdom of Abyssinia, on the coast of the Red Sea. The soil is unproductive; and its chief riches consist in salt and honey. It is governed by a prince nominally tributary to the negus, or emperor of Abyssinia.

DANDOLO (Henry), doge of Venice, a brave admiral

and politician. With a Venetian fleet he took Constantinople in 1203, and had the moderation to refuse to be emperor. He died in 1250.

DANET (Peter), abbot of St. Nicholas de Verdun, was one of the persons chosen by the duke of Montausier to write on the classics for the use of the dauphin. He had a share in Phædrus, which he published with notes and explications in Latin. He also wrote a dictionary in Latin and French, and another in French and Latin. He died at Paris in 1709.

DANGER, ISLES OF, three islands in the S. Pacific Ocean, seen by Commodore Byron in 1765, but were so surrounded by rocks and breakers, that it was unsafe to attempt to land. The commodore supposed them to be the islands seen by Quiros, in the beginning of the 17th century, and named Solomon's Islands. Long. 169. 28. W. Lat. 10. 15. S.

DANNEBERG, a town of Lower Saxony, capital of a district of the same name. It belongs to the elector of Hanover, and is seated on the Tetze, near the Elbe, forty miles S.E. of Lünenburgh. Long. 11. 29. E. Lat. 53. 14. N.

DANTE (Ignatius) a descendant of the poet, was born at Perugia, and took the habit of a Dominican monk. He became skilful in philosophy and divinity, but more so in the mathematics. He was invited to Florence by the great duke Cosmo I. and explained to him the sphere, and the books of Ptolemy. He read public lectures on the same subject, and had many auditors in the university of Bologna, where he explained geography and cosmography. Being returned to Perugia, he made a fine map of that city, and of its whole territory. The reputation of his learning caused him to be invited to Rome by Gregory XIII. who employed him in making geographical maps and plans. He acquitted himself so well in this, that the pope thought himself obliged to prefer him; and accordingly gave him the bishopric of Alatri, near Rome. He went and resided in his diocese; but Sixtus V. who succeeded Gregory XIII. would have him near his person, and ordered him to return to Rome. Dante was preparing for the journey, but was prevented by death, which seized him in 1586. He published at Florence, in 1569, a treatise Of the Construction and Use of the Astrolabe. He also wrote notes on the Sphere of Sacrobosco, on the Astrolabe, and on the Universal Planisphere. He made a sphere of the world in five tables; and was the author of some other small things.

DANVERS (Henry), a brave warrior in the end of the sixteenth, and beginning of the seventeenth century; and created earl of Danby by King Charles I. was the second son of Sir John Danvers, knight, by Elizabeth his wife, daughter and coheir to John Nevil, the last Lord Latimer. He was born at Danteley in Wiltshire, on the 28th day of June, 1573. After an education suitable to his birth, he went and served in the Low-country wars, under Maurice count of Nassau, afterwards Prince of Orange; and was engaged in many military actions of those times, both by sea and land. He was made a captain in the wars of France, occasioned in that kingdom by the league; and there knighted for his good service under Henry IV. king of France. Next, he was employed in Ireland, as lieutenant-general of the horse, and serjeant-major of the whole army, under Robert earl of Essex, and Charles baron of Mountjoy, in the reign of Queen Elizabeth. Upon the accession of King James I. he was, on account of his family's deserts and sufferings, advanced, on the 21st of July, 1603, to the dignity of a peer of this realm, by the title of Baron of Danteley; and in 1605, by a special act of parliament, restored in blood, as heir to his father, notwithstanding the attainder of his elder brother, Sir Charles Danvers, knight. Moreover, he was appointed lord president of Munster in Ireland, and in 1620, made governor of the isle of Guernsey, for life. By King Charles I. he was created earl of Danby, on

February 5, 1625-6; and made one of his privy-council, and knight of the order of the Garter. Being himself a man of learning, as well as a great encourager of it, and observing that opportunities were wanting in the university of Oxford for the useful study of botany, he purchased a piece of ground by the river Charwell, opposite to Magdalen College; which he encompassed with a curious wall of square polished stone, and replenished with a great variety of plants and herbs proper for the study of physic and botany. He founded also an almshouse and a free-school, at Malmesbury in Wiltshire. In his latter days he chose a retired life; and, upon what account is not well known, fell under the displeasure of the court. At length he died, at his house in Cornbury-Park in Oxfordshire, January the 20th, 1643-4, in the seventy-first year of his age; and was buried in the chancel of the parish-church of Danteley, under a noble monument of white marble, with an epitaph, which contains the best character that can be given of him. He was never married.

DANVERS (John), was younger brother and heir of Henry. He was also a knight and one of the gentlemen of the privy-chamber to King Charles I. and was so ungrateful and inhuman as to fit in judgment upon his gracious master, that unfortunate prince, and to be one of those who signed the warrant for his execution. He died before the restoration of King Charles II, but, however, all his estates both real and personal were confiscated in 1661. From Lord Clarendon we understand, he was neglected by his brother, and, by a vain expence in his way of living, contracted a vast debt, which he knew not how to pay, and being a proud formal weak man, between being seduced and a seducer, became so far involved in their counsels, that he suffered himself to be applied to their worst offices, taking it to be a high honour to sit upon the same bench with Cromwell, who employed and contemned him at once; nor did that party of miscreants look upon any two men in the kingdom with that scorn and detestation as they did upon Danvers and Midlam.

DARABGERD, or DARAB-GUISER, a town of Persia, in Faristan, said to have been founded by Darius. It is large, but not populous, and near it salt is found of various colours, white, black, red, and green. A considerable manufacture of glass is carried on here. It stands 116 miles E.S.E. of Schiras.

DARAH, or DRAS, a country of Africa; bounded on the N. by Morocco, Gezula, and Tafillet, and on the E. and S. by Zahara, and on the W. by Sus. A river of the same name flows through it. The principal produce is indigo and dates. The inhabitants are Arabs and Mahometans; and some of the districts of the country are dependent on Morocco.

DARAPOORY, a town of the peninsula of Hindoostan, in Myfore, 88 miles E. of Seringapatam. Long. 78. 26. E. Lat. 12. 11. N.

DARAPORUM, a town of the peninsula of Hindoostan, in Myfore, 36 miles E.S.E. of Coimbatore, and 75. W. of Trichinopoly. Long. 77. 30. E. Lat. 10. 42. N.

DAR-EL-HAMARA, a town of the kingdom of Fez, built by the Romans. Its trade consists in oil and corn; and it is seated on a mountain. Long. 6. 35. W. Lat. 34. 20. N.

DARGONNE (Dom Bonaventure), a religiousist of the Carthusian order, was born at Paris in 1640, and died in 1704. We have of his a very judicious work, entitled, *Un Traité de la Lecture des Pères de l'Eglise*; the best edition of which is that of 1697. He published also, *Des Melanges d'Histoire et de Littérature*, under the name of Vigneul de Marville, in 3 vols. 12mo; the last of which is said to be done by the abbé Banier. This is a very curious and interesting collection of critical reflections and literary anecdotes. He has been called to account by the critics for what he has said of Bruyere. He was the author of some other things.

DARIEN, a river and gulf of Terra Firma, which divide the provinces of Darien and Carthage. In 1695 the Scotch obtained a charter from William III., empowering them to form a settlement on the N.W. point of the gulf, where the country had never been occupied by the Spaniards, but continued to be possessed by the native Indians. This settlement excited such an alarm among the maritime powers of Europe, and particularly the jealousy of the Spanish court and of the English East-India Company, that the adventurers, meeting with every obstruction from the very administration that had granted their charter, were obliged to abandon the settlement.

DARLSTON, a village near Stone, in Staffordshire, where are the remains of a castle on a hill.

DAROCA, a town of Spain, in Arragon, on the Xiloca, 38 miles S.S.W. of Saragossa. Long. 1. 5. W. Lat. 41. 15. N.

DARORE, a town of the Deccan of Hindoostan, 80 miles E. by S. of Amednagar. Long. 76. 10. E. Lat. 18. 50. N.

DART, a river in Devonshire, which rises at the foot of Dartmoor Hills, crosses Dartmoor to Ashburton, and after passing Totneis, where it is navigable for small vessels, is joined by the Hareborn, and falls into the English Channel, at Dartmouth.

DARTMOOR, an extensive moorish tract, in Devonshire, bounded on the N. by bleak hills, and extending forward quite through the centre of the county to the sea. It contains about 80,000 acres, and is watered by the river Dart. Many sheep are bred here, but of a small kind, and subject to the rot. The chief riches of the inhabitants are their black cattle, which thrive well on the coarse four herbage.

DARWAR, a strong town of Hindoostan, in the kingdom of Mylore, and one of the sultan's frontier towns, 88 miles S. by W. of Vissapour, and ninety E.N.E. of Goa. Long. 75. 29. E. Lat. 16. 5. N.

DASSEN-EYLAND, or Isle of Deer, one of the three small islands to the N. of the Cape of Good Hope; so called on account of the great number of deer which were first carried thither in 1601. Here are also sheep whose tails weigh 19 pounds. Long. 18. 7. E. Lat. 33. 25. S.

DASSOUCCI, a celebrated French musician and poet of the 17th century, who published his own adventures, which are very odd, in the style of a buffoon. He relates, that he was born at Paris; that his father, an advocate in the parliament, was of Sens in Burgundy; that his mother was of Lorraine, a very little woman, and very prone to anger; that her husband and she, not being able to agree, parted by consent, after having divided their children and their substance; that he lived with his father at Paris, where he was ill-treated by a servant, who was his father's mistress; that at nine years of age he went to Calais, where he made people believe that he understood astrology, and was son to a famous calculator of natiivities; that, having by a little artifice cured a person who conceived himself sick, he passed for a magician; that he was obliged to leave Calais privately, the mob threatening to throw him into the sea. Bayle knows nothing more of him, till the time that the Duke de St. Simon got Lewis XIII. to hear him at Germain; when he hit that prince's humour by a drinking song of his own making, which it afterwards became the fashion to sing at court. The king listened to his songs ever after, and admitted him freely into his closet; and they called Dassouci, Phœbus Garderobin, because he had his lutes always in the king's wardrobe. He continued this game under Lewis XIV. but having an inclination to go to Turin, he left Paris about 1655. Arriving at Lyons, he found many temptations to detain him. He entertained with his music all the convents of singing nuns; and there was not one of those devout virgins, who had not

already a copy of his Ovid in a Merry Humour. This was the title of a work, wherein he translated part of Ovid's Metamorphoses into burlesque verse. He stayed three months at Lyons, in the midst of diversions, plays, and entertainments, being highly caressed by Moliere, and the Bejars; after which he went to Avignon with Moliere, and then to Pezenas, where the assembly of the states of Languedoc was held. He was maintained by those players a whole winter; and followed Moliere as far as Narbonne. Afterwards he went to Montpellier, where he was imprisoned, and very near being burnt, for a suspected commerce with a male. He continued three months at Montpellier after his release, and drew up an account of that Tragi-comical Adventure, for he calls it; which however he did not print, though the chief magistrate, who had seen it, gave him leave. He afterwards saw several towns of Provence; and went to wait on the Prince of Morgues at Monaco, who made him a handsome present.

Being arrived at Turin, he had some trouble to confuse by his presence the report of his execution, which had been read in the Burlesque Gazette. He laboured to procure a settlement in that court, and supposes he should have succeeded, if the musicians of the country had not grown jealous of him. He pretends, that the beauty of his poetry laid him open to the indignation of a poet of Auvergne, who criticised and prosecuted him: and adds, that he suffered much for having neglected the favourites, because he implicitly fancied it sufficient to make his court to their royal highnesses. Perceiving they grew cold towards him, he requested either to be dismissed, or to have a fixed pension; and, to his great mortification, obtained the former. About 1674 he published two small volumes, which he had compiled in the prison of the Chatelet at Paris. He was confined there at that time: but we know nothing of the particulars relating either to his confinement or his enlargement. Dassouci had several enemies: among the rest, Cyrano de Bergerac and Boileau. He was a very indifferent sort of man, as we learn from his own accounts and confessions: there is no occasion to depend upon the testimony and authority of his satirists for this.

DAVENANT (John), bishop of Salisbury, and a very learned man, was the son of an eminent merchant, and born in Watling-street, London, about 1570. He was admitted of Queen's College, Cambridge, in 1587, where he took his degrees in arts regularly. A fellowship was offered him about 1594, but his father would not suffer him to accept it, on account of his plentiful fortune; however, after his father's decease, he accepted of one, and was admitted into it in 1597. He took his doctor's degree in 1609, having long distinguished himself by his parts and learning; and the same year was elected Lady Margaret's professor of divinity. In 1614 he was chosen master of his college; and became so considerable, that he was one of those eminent divines, sent by James I. to the synod of Dort in 1618. He returned to England in May 1619, after having visited the most eminent cities in the Low-countries. In 1621 he was advanced to the see of Salisbury, and continued in favour during the remainder of James's reign; but in 1630-1 he incurred the displeasure of the court, by meddling, in a sermon preached before the king at Whitehall, with the predestinarian controversy; "all curious search into which" his majesty had strictly enjoined, in his declaration prefixed to the 39 articles in 1628, "to be laid aside." For this pretended contempt of the king's declaration he was not only reprov'd the same day, but also summoned to answer two days after before the privy-council; and, though he was dismissed without further trouble, and even admitted to kiss the king's hand, yet he was never afterwards in favour at court. He died of a consumption, April 20, 1641, to which, it is said, a sense of the sorrowful times he saw coming on did not a little

contribute; and was buried in Salisbury cathedral. He was a man of exemplary manners, and a great divine; but strictly attached to Calvinism with all its absurdities.

He wrote, 1. A Latin Exposition of St. Paul's Epistle to the Colossians, the third edition of which was printed at Cambridge in 1639. It is the substance of lectures, read by him as Margaret professor. 2. *Prælectiones de Duobus in Theologia Controversis Capitibus: de Judice Controversiarum, primo: de Justitia Habituali & Actuali, altero, Cant. 1631.* 3. In 1634, he published the questions he had disputed upon in the schools, 49 in number, under this title; *Determinationes Questionum quarundam Theologicarum.* 4. *Animadversiones* upon a Treatise lately published, and entitled, *God's Love to Mankind*, manifested by disproving his absolute Decree for their Damnation, Camb. 1641.

DAVENANT (William), younger brother to the former, and fourth son of Sir William Davenant, was educated at Magdalen-hall in Oxford, where he took the degree of B.A. in 1677. He translated into English from the French, a book, entitled, *Animadversiones* upon the famous Greek and Latin Historians, written by La Mothe le Voyer, who was tutor to Lewis XIII. He took the degree of M. A. in 1680; and about the same time, entering into orders, was presented to a living in the county of Surrey, by his patron Robert Wymond-fole, of Putney, esq. He travelled with this gentleman into France; and in the summer of 1681, was unfortunately drowned in a river near Paris, as he was swimming for his own diversion.

DAVENANT (Doctor Charles), an eminent civilian and writer, eldest son of the preceding, and educated in Cambridge: he wrote several political tracts; and likewise plays. He was (1685) impowered, with the master of the revels, to inspect the plays designed for the stage, that no immoralities might be presented. His *Essays on Trade* are in high esteem; and were lately reprinted in five vols. 8vo. Doctor Davenant was inspector-general of exports and imports; and died in 1712.

DAVENPORT (Christopher), a learned Englishman, was born at Coventry, in Warwickshire, about 1598, and educated in grammar-learning at a school in that city. He was sent to Merton College in Oxford at fifteen years of age; where spending two years, he, upon an invitation from some Romish priest, afterwards went to Douay. He remained there for some time; and then going to Ypres, he entered into the order of Franciscans among the Dutch there, in 1617. After several removals from place to place, he became a missionary into England, where he went by the name of Franciscus à Sancta Clara; and at length was made one of the chaplains to Henrietta Maria, the royal consort of Charles I. Here he did all he could to promote the cause of Popery, by gaining disciples, raising money among the English Catholics to carry on public matters abroad, and by writing books for the advancement of his religion and order. He was very eminent for his uncommon learning, being excellently versed in school divinity, in fathers and councils, in philosophers, and in ecclesiastical and profane history. He was, Wood tells us, a person of very free discourse, while his fellow-labourer in the same vineyard, Hugh Cressly, was reserved; of a lively and quick aspect, while Cressly was clouded and melancholy: all which accomplishments made him agreeable to Protestants as well as Papists. Archbishop Laud, it seems, had some knowledge of this person; for, in the seventh article of his impeachment, it is said, that "the said archbishop, for the advancement of Popery and superstition within this realm, hath wittingly and willingly received, harboured, and relieved, divers Popish priests and Jesuits, namely, one called Sancta Clara, alias Davenport, a dangerous person and Franciscan friar, who hath

written a Popish and seditious book, entitled, *Deus Natura, Gratia, &c.* wherein the thirty-nine Articles of the Church of England, established by act of parliament, are much traduced and scandalized: that the said archbishop had divers conferences with him, while he was writing the said book, &c." To which article, the archbishop made this answer: "I never saw that Franciscan friar, Sancta Clara, in my life, to the utmost of my memory, above four times, or five at most. He was first brought to me by Dr. Lindfild, but I did fear, that he would never expound the articles so, that the church of England might have cause to thank him for it. He never came to me after, till he was almost ready to print another book, to prove, that episcopacy was authorised in the church by divine right; and this was after these unhappy firs began. His desire was, to have his book printed here; but at his several addresses to me for this, I still gave him this answer: That I did not like the way which the church of Rome went concerning episcopacy; that I would never consent, that any such book from the pen of a Romanist should be printed here; that the bishops of England are very well able to defend their own cause and calling, without any help from Rome, and would do so when they saw cause; and this is all the conference I ever had with him." Davenport at this time absconded, and spent most of those years of trouble in obscurity, sometimes beyond the seas, sometimes at London, sometimes in the country, and sometimes at Oxford. After the restoration of Charles II. when the marriage was celebrated between him and Catherine of Portugal, Sancta Clara became one of her chaplains; and was for the third time chosen provincial of his order for England, where he died May 31, 1680.

He was the author of several works: 1. *Paraphrastica Expolitio Articulorum Confessionis Anglicanæ.* This book was, we know not why, much railed at by the Jesuits, who would fain have had it burnt; but being soon after licensed at Rome, all further rumour about it stopped. 2. *Deus, Natura, Gratia: sive, Tractatus de Prædestinatione de Meritis, &c.* This book was dedicated to Charles I. and Prynne contends, that the whole scope of it, as well as "the paraphratical Exposition of the Articles," reprinted at the end of it in 1635, was to reconcile the king, the church, and the articles of our religion to the church of Rome. He published also a great number of other works, which are not now of consequence enough to be mentioned.

DAVENPORT (John), elder brother of Christopher just mentioned, was born at Coventry, in 1597; and sent from thence with his brother to Merton College in 1613. He afterwards took a different rout from him; for whereas Christopher went to Douay, and became a Catholic, John went to London, and became a Puritan. He was minister of St. Stephen's in Coleman-street, and seemed by his fanatical brethren a person of excellent gifts in preaching, and in other qualities belonging to a divine. About 1630, he was appointed by certain factious and discontented persons, one of the feesees for the buying in impropriations; but, that project miscarrying, he left his pastoral charge about 1633, under pretence of opposition from the bishops, and went to Amsterdam. Here, endeavouring to be a minister in the English congregation, and to join with them in all duties, he was opposed by John Paget, an elder, on account of some difference between them about baptism; upon which he wrote, in his own defence, A Letter to the Dutch Classis, containing a just Complaint against an unjust Doer; wherein is declared the miserable Slavery and Bondage that the English Church at Amsterdam is now in, by Reason of the tyrannical Government and corrupt Doctrine of Mr. John Paget, their Minister, Amst. 1631. Two or three more pieces relating to this controversy were published by him afterwards; and such were his

parts and learning, that he drew away from them many of their congregation, to whom he preached and prayed in private houses.

In the beginning of the rebellion, he returned into England, as other Nonconformists did, and had a cure bestowed on him; but finding matters not go on agreeably to his humour, he went into New England, and became a pastor of New Haven there. He afterwards removed from thence to Boston in 1668, where he died the year following. He was the author of *A Catechism* containing the chief Heads of the Christian Religion, which was printed in London in 1659: several Sermons: *The Power of congregational Churches asserted and vindicated*: and of *An Exposition of the Canticles*, which has never been published.

DAVID (George), a most extraordinary heretic, was the son of a waterman of Ghent, and educated a glazier, or, as some say, a glass-painter. He began about 1525 to preach such whimsies as these, namely, that he was the true Messiah, the third David, nephew of God, not after the flesh, but after the spirit. "The heavens," he said, "being empty, he was sent to adopt children worthy of that kingdom; and to restore Israel, not by death, as Christ, but by grace." With the Sadducees, he denied eternal life, the resurrection, and the last judgment: with the Adamites he was against marriage, and for a community of women: and with the followers of Manes, he thought that the body only, and not the soul, could be defiled by sin. According to him, the souls of unbelievers ought to be saved, and those of the apostles damned. Lastly, he affirmed it folly to believe that there was any sin in denying Jesus Christ; and ridiculed the martyrs for preferring death to apostacy. A persecution being commenced against him and his followers, he fled first to Frieland, and from thence to Basil, where he lurked under the name of John Bruck. He died in that city in 1556, promising to his disciples, that he should rise again in three days; which, as it happened, was not altogether false; for the magistrates of Basil, understanding at length who he was, did, about that time, dig up his corpse, which, together with his writings, they caused to be burned by the common executioner. As great a madman as this George David was, he had his followers, which continued some time after his death.

DAVIES (Dr. John), was born in Denbighshire, and educated by William Morgan, afterwards bishop of St. Asaph. He was admitted a student of Jesus College, Oxford, in 1589, and afterwards became a member of Lincoln College in the same university. He was rector of Malloyd, or Manlyd in Merionethshire, and afterwards a canon of St. Asaph. He commenced doctor in 1616, and was highly esteemed by the university, says Wood, as well as versed in the history and antiquities of his own nation, and in the Greek and Hebrew languages; a most exact critic, an indefatigable searcher into ancient writings, and well acquainted with curious and rare authors. His works are, 1. *Antique Lingue Britannicæ nunc communiter dictæ Cambro-Britannicæ, à suis Cymrææ vel Cambriæ, ab aliis Wallicæ Rudimenta*, &c. 1621, 8vo. 2. *Dictionarium Latino-Britannicum*, 1632, folio. With this is printed *Dictionarium Latino-Britannicum*, which was begun and greatly advanced by Thomas Williams, physician, before 1600. It was afterwards completed and published by Dr. Davies. 3. *Adagia Britannica, Authorum Britannicorum nomina, & quando floruerunt*, 1632, printed at the end of the Dictionary before mentioned. 4. *Adagiorum Britannicorum Specimen*, MS. Bibl. Bodl. He also assisted W. Morgan, bishop of Landaff, and Richard Parry, bishop of St. Asaph, in translating the Bible into Welsh, in that correct edition which came out in 1620. He also translated into the same language (which he had studied at vacant hours for thirty

years) the book of *Revelation*, written by Robert Parsons, a Jesuit.

DAVIES (John), an eminent and learned critic, was the son of a merchant in London, and born there April 22, 1679. After being educated in classical learning at the Charterhouse school, he was, in 1695, sent to Queen's College, Cambridge; where he took the degree of B.A. in 1698. In 1701 he was chosen fellow of his college; and the year following took the degree of M.A. In 1711, having distinguished himself by several learned publications, hereafter to be mentioned, he was collated by Moore bishop of Ely to the rectory of Fen-Ditton near Cambridge, and to a prebend in the church of Ely; taking the same year the degree of LL.D. Upon the death of Dr. James, he was chosen master of Queen's College, March 23, 1716-17; and created D.D. in 1717, when George I. was at Cambridge. He died March 7, 1731-32, aged 53, and was buried in the chapel of his college; where a flat marble stone was laid over his grave, with a plain inscription. His mother, who was a daughter of Sir John Turlton, Knt. is said to have been living in 1743.

This learned man was not, as far as we can find, the author of any original works, but only employed himself in giving fair and correct editions of some Greek and Latin authors of antiquity. Thus, in 1703 he published in 8vo. 1. *Maximi Tyrii Dissertationes*, Gr. and Lat. ex Interpretatione Heinitii, &c. 2. *C. Julii Cæsaris, & A. Hirtii quæ extant omnia*, Cant. 1706, 4to. It was republished in 1727. 3. *M. Minucii Felicii Octaviani, Cant. 1707, 8vo.* It was printed again in 1712, 8vo. with the notes greatly enlarged and corrected, and the addition of Commodianus, a writer of the Cyprianic age. 4. Then he formed a scheme of publishing new and beautiful editions of Cicero's philosophical pieces, by way of supplement to what Grævius had published of that author; and accordingly put out, in 1709, his *Tufculanarum Disputationum, Libri quinque*, 8vo. This edition, and that of 1738, which is the fourth, have at the end the emendations of his intimate friend Dr. Bentley. The other pieces were published by our author in the following order: *De Naturâ Deorum*, 1718. *De Divinatione & de Fato*, 1721. *Academica*, 1725. *De Legibus*, 1727. *De Finibus Bonorum & Malorum*, 1728. These several pieces of Tully were printed in 8vo. in a fair and handsome manner; have been received with a general applause; and have passed, most of them, through several editions. He had also gone as far as the middle of the third book of Cicero's Offices; but being prevented by death from finishing it, he recommended it in his will to the care of Dr. Mead, who put it into the hands of Dr. Thomas Bentley, that he might fit and prepare it for the press. But the house where Dr. Bentley lodged, which was in the Strand, London, being set on fire through carelessness, as it is said, by reading after he was in bed, Davies's notes and emendations perished in the flames. 5. Another thing published by our learned author, which we have not mentioned, was, *Lactantii Firmiani Epitome Divinarum Institutionum*, Cant. 1718, 8vo.

DAVILA (Henrico Catherino), a celebrated historian, was born of an illustrious family in the Isle of Cyprus; but was obliged to leave his country, on its being taken by the Turks, in 1571. He first retired to Avila in Spain, whence his family supposed they had derived their name and origin; from thence he went to France, and made himself known at court under the reigns of Henry III. and Henry the Great. He there distinguished himself on several occasions by his valour; and at length went to Venice, where he had a very handsome pension settled upon him by that republic, in whole service his brother Lewis Davila had been a commander. Davila, while he was at Venice, wrote his admirable History of the Civil Wars of France, which contains every thing worth

notice that passed from the death of Henry II. in 1559, to the peace of Vervins in 1598. He was killed about the year 1635, by a gentleman of Verona; who, in a dispute about furnishing him with carriages in pursuance of his having a commission from the republic, discharged a pistol at Davila, and wounded him in such a manner, that he died soon after. Davila's son, a youth of about 18, being present, had the spirit to revenge the death of his father; for, instantly rushing upon the murderer, he cut him in pieces.

DAVIS (Henry Edwards), son of Mr. John Davis, of Windsor, was born July 11, 1756, and educated at Ealing, Middlesex, whence he removed to Balliol-College, Oxon, May 17, 1774, and took his degree about Jan. 1778, as B.A. In the spring of that year he distinguished himself amongst the earliest examiners of some remarkable assertions, and insinuations yet more extraordinary, introduced in the History of the Decline and Fall of the Roman Empire. So much accurate knowledge, and a judgment so well matured as that Examination discovered, has been rarely found at the age of twenty-one. The historian, in his Vindication, exerted very considerable efforts, though strongly assailed by veterans in literature, to defend himself against his juvenile opponent. Mr. Davis, in his Reply, manifested no ordinary degree of candour and firmness. Such proofs of learning, sagacity, and zeal for the Christian cause, drew the particular attention of men, eminent by their public station, their talents, and acquired advantages, and still more distinguished by their virtue and piety. In 1780, having entered into full orders, he was established, in a manner peculiarly to his honour, in a fellowship of his college; and, for some time before his death, was tutor; an office which he discharged with solicitude and constancy, too great for the sensibility of his mind and the delicacy of his constitution. A lingering illness removed him from the society of his many estimable friends, and deprived the public of his expected services. Feb. 10, 1784, without any apparent change between a placid slumber and death, he expired. He was buried at Windsor, which was the place of his birth. He had cultivated a taste for elegant literature, particularly in poetry, and occasionally wrote for the Gentleman's Magazine; the particulars cannot now be ascertained, except that in the Magazine for April 1782, p. 281, a letter signed C. and D. pointed out a very erroneous representation, for such it is presumed it will appear to impartial readers, in a passage of Mr. Gibbon concerning Gennadius. Of this the discovery belongs to Mr. Davis; though in the drawing of it, as the signature imports, a learned friend was concerned.

It may be added, that, before his publication of the Examination, he had given several proofs of an early genius; and as in this he resembled some eminent men, so he did also in another respect, being from his infancy of a very tender and delicate constitution. His apprehension was quick, his judgment correct; and in his application he was indefatigable.

DAVOS, a town of Switzerland, and capital of a jurisdiction of the same name, in the country of the Grisons. In the district are two lakes well furnished with fish, mines of copper, lead, and silver; and the inhabitants breed a great number of cattle: sixty miles S. E. of Zurich. Long. 27. 21. E. Ferro. Lat. 46. 40. N.

DAUN, a town of Germany, in the electorate of Treves, seated on the Moselle, at the foot of a mountain, on which is a castle, twelve miles N. of Mont Royal.

DAUPHIN, FORT, a fort built by the French, on the E. coast of Madagascar. Long. 45. 10. E. Lat. 24. 55. S.

DAWES (Sir William), an eminent English prelate, was the youngest son of Sir John Dawes, bart. and born at Lyons, near Braintree, in Essex, Sept. 12, 1671. He was educated at

Merchant-Taylor's school in London, where he made a great proficiency in classical learning; and was also tolerably versed in the Hebrew tongue, even before he was fifteen years of age; which was chiefly owing to the additional care that Kidder, afterwards bishop of Bath and Wells, but then rector of Rayne near Braintree, was pleased to take of his education. In 1687 he was sent to St. John's College in Oxford; but his father's title and estate descending to him, upon the death of his two elder brothers, about two years after, he left Oxford, and entered himself a nobleman in Catharine-hall, Cambridge. He took possession of his eldest brother's chambers, who died there just before of a fever, at the same time that his other brother, who was lieutenant of a ship, was unhappily drowned. After he had taken the degree of M. A. he visited his estate in Essex, and intended to make a short tour into some other parts of the kingdom, which he had not seen; but his progress was stopped by his happening to meet with Frances, the eldest daughter of Sir Thomas Darcy, of Braxfield-lodge in Essex, a fine and accomplished woman, whom he soon after married.

As soon as he arrived at the proper age, he was ordained deacon and priest by Compton bishop of London. He intended, from the very first, to enter into holy orders; and is said to have prepared himself for this, by making some of the most eminent English divines his study, while he was very young. Shortly after, he was created D.D. by a royal mandate, in order to be qualified for the mastership of Catharine-hall, to which he was unanimously elected in 1696, upon the death of Dr. John Echard. He did several beneficial acts to his college: particularly, he contributed liberally towards the finishing a chapel which his predecessor had begun; and, by his interest at court, procured the first vacant prebend of Norwich to be annexed, by act of parliament, to the mastership of Catharine-hall for ever. In 1696 he was made a chaplain in ordinary to King William; and shortly after, was presented by his majesty to a prebend in the church of Worcester. Sir William, it seems, had pleased the king so well in a sermon, preached at Whitehall, Nov. 5, 1696, that his Majesty sent for him, and without any solicitation gave him this prebend; telling him at the same time, that "the thing indeed was but small, and not worth his acceptance, but as an earnest of his future favour, and a pledge of what he intended for him." Nov. 10, 1698, he was collated by Archbishop Tenison to the rectory, and the month following, to the deanery of Bocking in Essex; where he behaved in a very charitable and exemplary manner.

After Queen Anne's accession, Sir William was made one of her chaplains, and was in a fair way for some of the highest dignities in the church. Accordingly, though he missed the bishopric of Lincoln, which was vacant in 1705, yet her Majesty, of her own accord, named him to the see of Chester in 1707. The reason of his missing Lincoln was his having, in a sermon upon Jan. 30, uttered some bold truths, which were not agreeable to certain persons in power; who took occasion from thence to persuade the queen, contrary to her inclination, to give it to Dr. Wake, afterwards archbishop of Canterbury. This, however, made no impression upon Sir William; and, therefore, when he was told by a certain nobleman, that he had lost a bishopric by his preaching, his reply was, that "as to that he had no manner of concern upon him, because his intention was never to gain one by it." In 1713-14, he was translated to the archiepiscopal see of York; at which time he was also made a privy-councillor of state. He continued above ten years in this high station, much honoured and respected; and then a diarrhoea, to which he had been subject some time, coming to be attended with a fever, and ending in an inflammation of his bowels, put a period to his life, April 30, 1724. He was buried in the chapel of Catharine-hall, Cambridge.

near his lady, who died Dec. 22, 1705, in her 29th year. He had seven children, three of which only, namely, Elizabeth, Jane, and Darcy, survived him.

He was the author of several things, some of which were published by himself, and others after his decease, under the title of his *Whole Works*, with a Preface, giving some Account of the Life, Writings, and Character of the Author, 1733, in 3 vols. 8vo. Those published by himself were, 1. *An Anatomy of Atheism*, 1693. This is a poem, consisting of five sheets, and was written by the author before he was eighteen years of age. It is more remarkable for its argument and easiness of diction, than for any briskness and force of imagination. 2. *The Duties of the Closet*, &c. written before he was 21 years of age. 3. *The Duty of Communicating explained and enforced*, &c. composed for the use of his parishioners at Bocking. 4. *Sermons preached upon several Occasions before King William and Queen Anne*, 1707, 8vo. dedicated to that queen. 5. *A Preface to the Works of Bishop Blackall*, published in 1723.

DAWES (Richard), an English scholar, celebrated for the publication of a work, entitled, *Miscellanea Critica*, was born in 1708; and, after a school-education under Mr. Anthony Blackwall, admitted of Emanuel College, Cambridge, in 1725. In 1736 he published a specimen of a Greek translation of *Paradise Lost*; of which, in his preface to the *Miscellanea Critica*, he had candour enough to point out the imperfections himself. Mr. Dawes died in 1766, and left some MSS. to which Mr. Burgess, who afterwards published an improved edition of the *Miscellanea Critica*, had access. There are some others in Dr. Aikew's collection, who bought Mr. Dawes's library.

DAX, or **Acas**, an ancient town of France, in the department of Landes, with a bishop's see. Here are some famous hot baths, the spring of which discharges 543 cubic feet of water in 15 minutes. It is seated on the Adour, 24 miles N.E. of Bayonne. Long. 1. o. W. Lat. 43. 42. N.

DAY (Thomas), an eminent miscellaneous writer, the only son of Thomas Day, esq. one of the collectors outwards of the customs in the ports of London, was born in the year 1748. He received his education at Charter-house, and removed thence to Oxford. He afterwards made a tour on the Continent, and, on his return to England, entered himself of the society of the Middle Temple, and was called to the bar. But, although possessed of great eloquence, with a mind not only able to comprehend, but to improve the modes of judicial proceedings, he was disgusted with the technical nicety of legal process; and being possessed of an ample fortune, much augmented by the accumulation of a long minority, he declined the emoluments of the law, and devoted his time to literary pursuits. In 1777 he married Miss Esther Milnes, of Wakefield, in Yorkshire; and with this lady he lived retired many years at Ainsley, in the county of Surrey; where he amused himself with the occupation of a large farm, more for the sake of maintaining a number of poor families whom he employed around it, than with any view to his own advantage. He occasionally interfered in the politics of the times, with the honest zeal of a disinterested patriot, and the manly firmness of an independent country gentleman. But, on the 28th of September, 1789, a period was put to his valuable life by a fall from his horse, as he was riding out with some gentlemen in Berkshire.

Mr. Day's first publication, in 1773, was *The Dying Negro*, a poetical epistle. In 1776 he published another poem, entitled *The Devoted Legions*, addressed to Lord George Germaine, and the commanders of the forces against America.

In 1783 he produced the *History of Sandford and Merton*; a work of great importance to youth, and which he assisted.

It afterwards extended to three volumes 12mo. It consists of a variety of tales interwoven with a story, in which two children and their tutor are the principal characters. This work was followed by another, with the same benevolent views, entitled *The History of Little Jack*, and printed in 1783, in the *Children's Miscellany*. Mr. Day likewise published occasionally many political productions; 1. *Reflections on the present State of England, and the Independence of America*. 2. *Fragment of an original Letter on the Slavery of the Negroes*. 3. *A Dialogue between a Justice of the Peace and a Farmer*. 4. *The Letters of Marius; or, Reflections upon the Peace, the East-India Bill, and the present Crisis*. 5. *A Letter to Arthur Young, esq. on the Bill now pending in Parliament to prevent the Exportation of Wool*.

DEADMAN'S-HEAD, a cape in Cornwall, between St. Maw's and Fowey.

DEAFNESS (*Encycl.*). Under that article we have noticed an invariable consequence attending those who have the misfortune to be born *totally deaf*; namely, that they are also, by a natural consequence, *dumb* also. We have also mentioned the names of ingenious men who have found means to supply these lamentable defects in a great degree, and give to society many useful members. To their assistance, however, the poor could by no means attain, and this became an inducement with a few benevolent gentlemen, possessing an abundance of the temporal blessings of Providence, to appropriate a part of their superfluity to the purpose of raising these poor *automata* to a state of intellectual existence and usefulness, by opening a school for their instruction at Bermondsey.

On making enquiry into the nature and extent of this institution, it appears that, although it is in a prosperous condition, when the date (1792) of its establishment is considered; yet it is far from being sufficiently opulent to extend assistance to all who stand in need of it. It was the wish of its founders to have confined their bounty to instruction only; but receiving applications for relief from the most distant parts of the kingdom, it was found impracticable to fix on a situation where the children might have been daily collected: they were therefore obliged to add to it board and lodging, which necessarily contracted the sphere of their benevolence.

The number of *deaf* and *dumb* persons in this country is supposed to amount to several hundreds; more than 80 of whom, of a proper age, that is, between nine and fourteen, have applied for admittance; but the funds of the institution have not enabled the governors to receive above half that number: some have received instruction and been discharged, capable of expressing their ideas, and acknowledging their gratitude; and 35 are now in the asylum.

Their education consists in learning to speak and read articulately; to write, cypher, and understand language; and a manufactory is about to be erected adjoining the school, where some of the boys are to be instructed in the art of a taylor; others in that of a shoemaker; and the girls are to be taught to make stays; by which they will be rendered capable of earning their own maintenance, and becoming useful members of society.

From this account it appears, that there are at this moment upwards of 40 children, proper objects of this institution, to whom, for want of more liberal support, the governors cannot extend relief; and who, being unable to earn their own subsistence, are heavy burthens to their indigent parents; many of whom have large families, and are scarcely able to procure the common necessities of life.

DEAN, a town in Gloucestershire, with a market on Monday. It had its name from the forest of Dean, in which it is

seated, 11 miles W. of Gloucester, and 112 W.S.W. of London. Long. 2. 31. W. Lat. 51. 50. N.

DEAN, a forest in Gloucestershire, including that part of the county which lies between the Severn and the shires of Monmouth and Hereford. It contains four market towns and 23 parishes. It is fertile in pasture and tillage, bears very fine oaks, and has rich mines of iron and coal. It was once reckoned the chief support of the English navy; and the Spanish armada, it is said, was expressly commissioned to destroy it. It is now thinned by frequency of felling, and narrowed by increase of cultivation, though a few deer still continue to run wild in its recesses. The forest of Dean, and the vale of the same name, abound in orchards, which produce great plenty of excellent cyder.

DEBALPOUR, a town of Hindoostan Proper, capital of a district in the country of Moultan. It is situated on the great road from Delhi to Moultan, 146 miles S. of Lahore, and 190 E. by S. of Moultan. Long. 73. 50. W. Lat. 29. 20. N.

DEBEN, a river in Suffolk, which rises near Dobenham, and flows to Woodbridge, where it expands into a long narrow arm of the German Ocean, a little to the N. of Harwich.

DEBENHAM, a town in Suffolk, with a market on Friday, seated near the head of the Deben, on the side of a hill, 24 miles E. of Bury St. Edmunds, and 84 N.E. of London. Long. 1. 17. E. Lat. 52. 22. N.

DEBTOR (*Encycl.*). By the act for relieving insolvent debtors, 41 Geo. III. c. 70. gaolers are to make out alphabetical lists of prisoners, who, on March 1, 1801, or since, and at the time of making them out, were in custody for debt, stating at whose suit each prisoner is detained, which lists are to be delivered upon oath to the quarter sessions; to be kept by the clerk of the peace, and may be examined *gratis*.

Three copies of lists to be fixed up in each prison ten days before the session.

Prisoners, on March 1, 1801, for debts not exceeding 1,500l. conforming to this act, to be discharged.

Persons discharged from prison after March 1, 1801, and before the passing of this act, without their consent, entitled to the benefit of this act, on surrendering themselves at sessions.

Likewise persons imprisoned before the passing of this act for any debt which they shall have been imprisoned, at the suit of the same plaintiff, before March 1, 1801, entitled to the benefit of this act.

Justices, on petitions of the prisoners, delivering schedules of their estates, may issue warrants for bringing them to the quarter session.

Two justices may, upon petition from debtors, assemble their courts as soon as may be after passing this act, for the purposes thereof, and appoint days for the discharge of prisoners.

Schedules to remain with the clerk of the peace for inspection.

Debtors intending to apply for their discharge, to give previous notice thrice in the London or Dublin gazette; and if they be in custody in any gaol out of London, or in any gaol out of Dublin, then also in some newspaper which shall be published near them; and for each notice the prisoner shall pay the sum of 4d. and no more.

Debtors to deliver schedules to the gaoler previous to the first notice, and for neglect to be remanded to prison.

Gaoler to attest signatures to schedules, and to give copies to debtors, and also to creditors demanding them, on penalty of 20l.

Notice shall be signed by the debtor and gaoler.

Debtors applying at the session, proving notices were duly inserted, shall, in open court, upon oath, deliver in signed schedules, containing certain particulars.

Schedule and oath to be subscribed by the debtor, and to remain with the clerk of the peace for perusal of creditors.

Court, at the request of a creditor, may examine gaolers on oath; and the debtor's oath not being disproved, the court to order his discharge.

Estate and effects of discharged debtors vested in the clerk of the peace, who is to assign the same to such creditors as the court shall direct, in trust for the whole. And assignees are to get in effects, and sell them. Assignees are also to make dividend within three months, first verifying their accounts on oath. Thirty days' notice of making dividends to be given. No creditor to share till he has proved his debt. Reality of debts may be enquired into at the session. Surplus of effects to be paid the debtor.

Creditors for annuities, or money payable at any future time, to receive dividends as under a commission of bankrupt.

Powers of clerk of the peace for the county of Lancaster to extend to his deputies.

Estates of debtors, not inserted in schedules, to be vested in the clerk of the peace.

Holders of securities, without consideration given, not entitled to any benefit.

Estates to be vested in the clerk of the peace for the time being.

No suit in equity to be commenced without consent of the majority in value of creditors.

Schedules to be produced by clerks of the peace to creditors, and signed copies to be evidence.

Clerk of the peace refusing to produce schedules, &c. to forfeit 10l. with treble costs.

Assignees to compound with lords of manors for copyhold or customary estates.

The debtors right only to be affected by this act.

Act not to prevent mortgages, &c. taking place of claims of an inferior nature.

Power of leasing lands or over real or personal estate, vested in assignees.

The acting gaoler at the time of delivering the lists to take the oath.

At the session, on request of creditors, gaolers to be sworn.

At request of creditors, gaolers may be examined on oath at the sessions touching commitments.

Debtors forswearing, to be deemed guilty of perjury.

Persons discharged not liable for debts prior to March 1, 1801.

Prisoners are not to be discharged of debts subsequent to March 1, 1801.

Prisoners who, on application as insolvent debtors, have been remanded back, and since discharged without their consent, entitled to the benefit of this act.

Act may be pleaded to any action of escape.

Act may be pleaded generally by prisoners.

This act not to extend to attorneys, or servants, embezzling money; nor to persons obtaining money on false pretences. Prisoners remanded to prison under any insolvent act for fraudulently obtaining money, shall not receive any benefit under this act; nor persons charged in execution for damages recovered in any action for criminal conversation; nor persons removing effects of the value of 50l. liable to be distrained for rent; nor persons selling or assigning effects to defraud creditors.

Gaolers to permit prisoners to be spoken with, on penalty of 40l.

Gaolers making false entries, to forfeit goal.

Debtors refusing to discover the trade and abode of the person at whose suit detained, or to come to the lodge, shall be excluded the benefit of this act.

Justices may hold a session at or near the county gaol.

Prisoners in custody for fees, &c. claimed by gaolers, or other officers of the prison, shall be discharged.

Act not to extend to debtors to the crown, or offenders against revenue laws, unless the treasury certify their consent.

Determination of justices to be final, unless the prisoner get rid of the objections to his discharge.

Estates of which prisoners are seized in jail to be delivered up to creditors.

Affinees may apply for the further examination of debtors to two justices.

Justices to call before them debtors, and if they refuse to appear, may commit them.

Reward of 20l. per cent. for discovering any part of debtor's estate not comprised in schedule.

Discharge of prisoner fraudulently obtained, void.

Affinees, with consent of majority in value of creditors, may compound for debts, and submit disputes to arbitration.

Any person concealing estates of debtors, shall forfeit 100l. for every offence, and also double the value of the estate so concealed.

If assignees die, others may be chosen.

Courts, on complaint, may remove assignees.

Where mutual credit has been given, the balance to be stated.

Prisoners, for not paying monies awarded, costs, &c. entitled to the benefit of this act; and also prisoners on processes out of courts of conscience.

No persons who have taken the benefit of any insolvent act within five years, to be entitled to relief under this.

Affirmation of quakers to be taken.

This act not to extend to Scotland.

DECAPITATION, the act of beheading, or severing the head from the body; a mode of public punishment exercised in this and some other countries.

Among other singular questions lately agitated in France and Germany, the following is not the least curious: "*Whether the separated head of a person suffering on the scaffold be still, for a certain time, conscious of its sufferings?*" This question was proposed at the time the guillotine was first adopted as the instrument of public execution in France; and the writings which appeared on this apparently whimsical subject, were numerous. Professor Soemmering maintained in a particular treatise, first printed in the *Moniteur*, that the consciousness of the sufferer still continued for some time; and the professor is so far persuaded of the truth of this assertion, that in his opinion, the severed head would still emit sounds, if it were not separated from the organs of speech, as well as those of respiration.

Professor Wedekind controverted this opinion, and defended the French method of beheading as the quickest and least painful species of death, by which all consciousness is at once intercepted and annihilated: he says, that the blood-vessels of the separated head are, *ipso facto*, instantly and completely emptied of the blood, and that the organ of the mind is thus rendered totally inactive; consequently, the head cannot be conscious, either of its former or present state.

Mr. Cloßius, of Tübingen, though not fully convinced that the head, in a severed state, retains consciousness, yet considers this fact as highly probable, and on the whole, agrees in opinion with Soemmering. He dwells at considerable

length, in his treatise *On Decapitation*, upon the objections started by Wedekind, and endeavours to prove that the blood-vessels of the head are by no means so quickly and completely emptied, as the professor is disposed to think; and that even without an actual circulation of the blood, there may still remain some activity and energy in the brain. He produces in support of his hypothesis, a variety of arguments, derived partly from analogy and a comparison of the symptoms of a person beheaded with those observed in similar situations; and partly from appearances which have been noticed in individuals executed by the sword or guillotine. On account of this probability, ought not the dictates of humanity to be listened to, and instead of beheading, should not another mode of execution be devised, by which the deadly blow, and the complete annihilation of the natural structure of the brain, might take place at the same instant? Such, for instance, would be a sudden and violent convulsion of the brain, a mortal thrust on the stomach, and the like.

Another German writer on this subject, C. A. Eschenmayer, combats the opinion of Soemmering, but deals so much in confused philosophic speculations and vague hypotheses, that we shall forbear taking notice of what he advances; and proceed to give some account of a French treatise, entitled *Opinion du Citoyen Sue, sur le Supplice de la Guillotine*; a Paris, 16 pp. 8vo.—Citizen Sue, not contented with asserting that the head still continues to live, and to feel the most excruciating pain, as long as the blood remains warm in the smallest vessels, maintains that the lower part of the body also must suffer, after the head has been struck off. His arguments are not a little curious. He compares the act of beheading with that of amputation of a limb; as it has been observed that persons have felt, or at least imagined that they felt, pain in a limb, after being separated from the body by a surgical operation, as also after a dislocation of the vertebrae; that the upper parts of the body remain sensible and alive, while the lower extremities are lifeless and insensible to pain. The incongruity of this mode of reasoning from analogy is so palpable that it requires no refutation.

The author quotes various instances of preternatural births, or monsters born without a brain, and spinal marrow, on which he grounds his conjecture, that the lower extremities of the body are still sensible to pain, after a separation of the head has taken place. But, besides the obvious inconsistency in this comparison, it requires to be previously proved, that such monsters have ever had consciousness, and suffered pain, on account of the unnatural structure of their bodies. The remarkable facts witnessed by the author, during a number of executions at Paris, and related in this treatise; for instance, the singular phenomenon of smiling, or rather of blushing, in the trunkless head of Madame Cordet; the assassin of Marat, are no doubt curious, but not conclusive.

The subject of dispute is indeed such as admits of no positive decision; for the feelings of a person, after the mortal blow has been given by the sword or guillotine, cannot be ascertained, and we may pronounce it impossible for human reason to form an adequate conception of their greater or less duration. If there exist a something within the body, which after its dissolution hastens towards another destination, in which we shall not be insensible to agreeable or disagreeable sensations, this something will no doubt also possess the consciousness of its situation, whether the body has been destroyed by a putrid fever, by poison, by a concussion of the brain, or by any other mode of depriving or taking away life. It does not, indeed, here, depend upon the state of the circulation of the blood, or other relations, as connected with the body; for it must be admitted, that this something, if it continue

after and without the body, has no connection with corporeal causes, organs of the mind, or the like.

DECCAN, an extensive tract of country in Asia, which, according to the signification of its name, the South, has been supposed to include the whole regions of Hindoostan Proper. But, in its more accurate sense, it contains only the countries situate between Hindoostan Proper, the Carnatic, the Western Sea, and Orissa; namely, the provinces of Candesh, Dowlatabad, Vissapour, Golconda, and the W. part of Berar. It is bounded on the N. by the river Nerbudda, by Bengal, and by Bahar; and the river Kistna forms its separation on the S. from the peninsula of Hindoostan. All this vast country was once a province of the Mogul empire. Candesh, Vissapour, and a part of Dowlatabad, are subject to the Mahrattas; the remainder to the nizam of the Deccan.

DECCAN, the dominions of the nizam of the Deccan, comprising Golconda, the principal part of Dowlatabad, and the western part of Berar; the latter subject to a tribute of a fourth part of its net revenue to the Berar Mahrattas. His territories are bounded on the N.W. by the Poonah Mahrattas, on the N. by the Berar Mahrattas, on the E. by the Northern Circars, and on the S. by the Carnatic and Mysore. By family succession, in 1780, the nizam became possessed of the districts of Adoni and Tachore, and of the Guntoor Circar; and by the peace of 1792 he had a share of the country cessions made by Tippoo Sultan, including Kopaul, Cuddap, and Gangecolla. His dominions (without including the cessions) are supposed to be 430 miles from N.W. to S.E. by 300 wide. His capital is Hydrabad.

DECISE, an ancient town of France, in the department of Nievre, seated in an island formed by the Loire, 16 miles S.E. of Nevers. Long. 4. 31. E. Lat. 46. 50. N.

DECKENDORF, a town of Lower Bavaria, seated near the Danube, 37 miles S.E. of Ratibon. It was taken by the Swedes in 1641. Long. 12. 55. E. Lat. 48. 42. N.

DECKER (Thomas), a writer in the reign of James I. and being a contemporary with Ben Jonson, became more eminent by having a quarrel with that great poet, than he would perhaps otherwise have done from the merit of his own works. What the original occasion of their contest was, is unknown; but Jonson, who certainly could never "bear a rival near the throne," has, in his Poetaster, the Dunciad of that author, among many other poets whom he has satirized, been peculiarly severe on Decker, whom he has characterized under the name of Crispinus. This compliment Decker has amply repaid in his Satyromastix, or the Untrusting a humorous Poet, in which, under the title of young Horace, he has made Ben the hero of his piece. Although, as we before observed, Decker was but a middling poet, yet he did not want his admirers, even among the poets of his time; some of whom thought themselves not disgraced by writing in conjunction with him;—Webster having a hand in three of his plays, and Rowley and Ford joining with him in another. His Honest Whore, and the comedy of Old Fortunatus, are allowed to be solely his, which are said to contain beauties, in respect to character, plot, and language, equal to the abilities of any of those authors that he was ever assisted by; and indeed in the former, equal to any dramatic writer (Shakspeare excepted) that this island has produced.

The precise time of this author's birth and death are not recorded; yet he could not have died young, as the first play we find of his writing was published in 1600, and the latest date we meet with to any other is in 1638, except the Sun's Darling, which, Langbaine observes, was not published till after the death of its author.

DECREET, in the law of Scotland, a final decree or judgment of the lords of session, from which an appeal only lies to parliament.

DECREET-Arbitral, in Scots law, the sentence or judgment of one to whom parties voluntarily submit the determination of any question betwixt them.

DEDDINGTON, a town in Oxfordshire, with a market on Tuesday. It was anciently a corporation, and sent members to parliament in the reign of Edward III. It is 16 miles N. of Oxford, and 70 W.N.W. of London. Long. 12. 1. W. Lat. 52. 2. N.

DEE, a river of Scotland, which rises in Aberdeenshire, amid the mountains of Mar Forest, and flows through a wild country till it reaches the fertile vale of Braemar, whence it proceeds in an easterly direction to Aberdeen, below which it falls into the British Ocean.

DEE, a river of Scotland, which rises in the N.W. part of Kirkcudbrightshire, and joining the Ken, below New Galloway, falls into the Irish sea at Kirkcudbright.

DEED (*Encycl.*). Any indenture (except parish indentures), lease, or deed-poll; and any charter-party release, contract, or other obligatory instrument; or any procuration or letter of attorney; for every 15 common law sheets of 72 words each, 5 W. & M. c. 21. 6d. 9. and 10 W. III. c. 25. 6d. 12 Anne. f. 2. c. 9. 6d. 30 Geo. II. c. 19. rs. 16 Geo. III. c. 34. rs. 17 Geo. III. c. 50. rs. 6d. 23 Geo. III. c. 58. rs. 35 Geo. III. c. 30. rs. 37 Geo. III. c. 90. 3s. 41 Geo. III. c. 10. 3s. 41 Geo. III. c. 86. 2s. Total fifteen shillings.

And moreover, by 37 Geo. III. c. 111. there shall be paid upon every deed which shall be made after Aug. 1. 1797, an additional stamp duty of 10s. over and above all duties now payable on the vellum or paper whereon such deed shall be engrossed (but this is upon the first skin only), the provisions of this act being as follow:

This is not to extend to any bond or letter of attorney; nor any deed whatever, bearing date Aug. 1797.

Also it shall not extend to any indenture of apprenticeship, where a sum not exceeding 10l. shall be given; nor to any lease for not exceeding twenty-one years, the full improved annual value whereof, and rent reserved therefor, shall not be more than 10l.* nor to any lease for lives, or years determinable on lives, where the fine shall not exceed 20l. nor the rent reserved 40s.

Nor shall any deed be subject to the payment of any greater duty than the sum before mentioned, or to be stamped on more than one skin, with the additional stamp; or to be stamped with more than one such stamp.

Nor shall the duty by this act imposed be liable to the regulations respecting the stamping of parchment and paper, according to the number of common law sheets engrossed thereon.

Upon payment, within 60 days, after the date of the deed, of the duty hereby imposed, the stamp-officers may stamp any

* But by 39 and 40 Geo. III. c. 42. the above duties shall extend to every deed which by law may form, or is intended to form, a part of any conveyance of lands or tenements, whereby twenty-one years, whatever may be the value thereof; and stamped, may be taken to the office, at any time within twelve months after July 9, 1800, to be stamped upon payment of duty.

vellum, parchment, or paper, on which any deed shall have been engrossed, or on which any deed shall be intended to be engrossed, with the additional stamp.

And if the duty shall not be paid within sixty days, then it shall be lawful to lend the deed to the head office, and on payment of the duty; and the further sum of 10*l.* by way of penalty, the same may be stamped.

But grants, conveyances, and assurances under the seal of the duchy of Lancaster, according to 19 Geo. 3. c. 45, where the consideration does not exceed 10*l.* are exempted by that act, and 39 and 40 Geo. 3. c. 72, from all duty.

Note, the number of stamps required to be used on deeds are one for every fifteen common law sheets (of 72 words each) contained in the deed, or in any schedule or instrument annexed thereto, or any indorsement thereon.

DEERHURST, a village in Gloucestershire, three miles S. of Tewkesbury, subject, by its low situation, to frequent inundations from the Severn. Here was a palace built, and afterwards converted to a monastery in 715, which the Danes destroyed; but it was rebuilt and made an alien priory, under the patronage of the abbot of Tewkesbury. Its being rebuilt in the reign of Edward the Confessor, and its consecration by the then bishop of Worcester, is denoted by a Latin inscription on a stone, which, in 1675, was dug up in an orchard.

DEFECATE (*Encegel*). The various ways in which defecation, or CLARIFICATION as it is otherwise called, may be performed, are very fully set forth in the following observations of Citizen Parmentier.

"The term *defecation* or *clarification* is generally applied in pharmacy to an operation, by means of which liquids are freed from the foreign substances that impair their transparency.

"This operation, simple as it may appear to be, nevertheless merits particular attention; especially when we consider the advantages which are obtained from it in the chemical and pharmaceutical arts. I therefore thought it might be useful to communicate some general observations on clarification.

"It is not my intention, in this place, to discuss the different methods employed for the process of clarification, nor to enumerate in detail the respective effects which they produce upon the different substances to which they are applied; but I shall content myself with pointing out the principal phenomena that are observed in operations of this kind.

"The end propoed, when we wish to clarify a fluid, is to free it from substances which, without being dissolved, remain suspended in it, and impair its transparency and limpidity; but these substances are separated sometimes by subsiding or filtration; sometimes by the action of the air, of heat, of light, of motion, and of fermentation; sometimes finally, by the aid of agents, which, in uniting the particles dispersed in the liquid which we wish to clarify, often change their nature, and no longer permit them to remain in the state in which they were before. We shall commence an enquiry with considering spontaneous clarification. This never takes place, unless when the particles, that are to be separated, have a specific gravity decidedly inferior or superior to that of the fluid in which they are suspended; they can then unite either at the lower part of the fluid or at its surface, and there form a mass which may very easily be removed, if the separation has been complete; the fluid then possesses all the transparency that can be desired, and which the most accurate filtration cannot augment.

"This mode of clarification is sometimes subject to several inconveniences, the chief of which are, that it requires a considerable length of time to effectuate it, and that, during this interval, it contributes to favour the formation of new pro-

ducts, which, changing the composition of the fluid that was to be clarified, do not leave it the same as it was previous to its clarification, independent of the substances that impaired its transparency. We find a very striking example of what happens in this case, when we consider the circumstances with which the spontaneous clarification of the juices of plants or fruits is attended. These juices, when fresh expressed, are always turbid; they nevertheless become clear by imperceptible degrees; but then their nature is no longer altogether the same as it was before; for they contain products which would not have been found in them if they had been clarified immediately after having been expressed. Hence it also proceeds, that the juices of the lemon, the gooseberry, the Seville orange, &c. when examined before or after their spontaneous clarification, are so widely different with respect to their taste, smell, colour, and economical properties.

"In general, we may establish it as a constant rule, that all the liquids susceptible of fermentation are those in which spontaneous fermentation produces the effects of which we have just been treating; whilst these effects do not take place in those which are little or not at all susceptible of fermentation, and the transparency of which is impaired merely by particles which are incapable of exerting any operation upon the constituent parts of these liquids.

"Thus, for example, water, alcohol, ether, oil, &c. when deprived of their perfect transparency, may easily acquire it again by spontaneous clarification, without the smallest change taking place in the composition of these fluids; for, if we examine them after they have been clarified, we shall find them similar to others that have not been subjected to the process of clarification.

"The second process for clarifying fluids consists in filtering them; but this operation can never be performed without the aid of intermediate substances, the very minute pores of which suffer only the fluid to pass through them, but intercept the passage of all the particles that were merely suspended in it.

"An infinite variety of substances are used as instruments of filtration: paper, woollen, linen and cotton cloth, carded cotton, sponge, sand, earths, pounded glass, charcoal, porous stones, &c. all these substances may be usefully employed in this operation; but their nature and purity ought to be examined, especially when we have to filter saline substances.

"It is the business of the chemical and pharmaceutical operator to choose, amongst the different kinds of filters, that which, whilst it is the best adapted for effecting the clarification of the fluids, is at the same time incapable of producing any change in its constituent principles. Now this choice is to be determined by the knowledge which we have of the nature of the fluid, and of the species of filter which it may be proper to employ.

"If it be an aqueous, vinous, spirituous, or oily liquid, paper may be employed without any inconvenience, provided it be of a good quality. This last condition is to be strictly attended to, otherwise the product of the filtration will often be defective.

"Paper is known to be a kind of web, formed of vegetable fibres, that have undergone various preparations. The particles of these fibres are intermingled in such a manner, as to leave between them pores, the tenuity of which is always proportionate to the state in which the paste was at the moment when it was converted into paper. If this tenuity be considerable, the pores are soon obstructed by the sediment which is deposited by the liquid we wish to filter; the filtration then ceases to take place. When, on the contrary, the pores are very wide, the filtration is effected rapidly, but always in an imperfect manner; for, whilst the liquid passes through the

filter, it carries with it the more minute particles that were suspended in it, and only the grosser ones remain upon the surface of the filter.

"The great art, therefore, is to choose paper, the pores of which have precisely the size requisite for admitting only the fluid that is to be filtered, but none of the particles that impair its transparency.

"We meet with two sorts of paper in commerce, which nearly produce this effect, and, though they are not always so perfect as might be desired, they are those which have hitherto been preferred. The one, which is semi-white, bears the peculiar appellation of *papier Joseph*; the other is a kind of grey paper, but not so coarse as that which is used for wrapping different cheap articles of merchandize: both of them are manufactured without size.

"The whiteness of the *papier Joseph* shews that it has been manufactured with a purer paste than that which has served for the manufacture of the grey paper; the liquids that have been filtered through it are always transparent; but it has the inconvenience of tearing very readily, and its pores are soon obstructed, so that the filtration goes on but slowly.

"The grey paper can serve for a greater length of time to furnish all clear liquids; but, as the paste with which it has been manufactured has not been so well purified as that of the *papier Joseph*, it always communicates to the liquids a disagreeable taste, which proceeds from the solution of the foreign substances contained in this paper. This is also the reason why certain fluids, such as whey, wine, spirituous compounds, and other potable liquids, that have been filtered through grey paper, have always a smell and taste, which are easily recognised by experienced organs. Hence it proceeds, that, amongst these liquids, some are more susceptible of spoiling than when they have been filtered through the *papier Joseph*.

"The nature of the paper demands our attention most of all when we have to filter saline solutions. If we have employed grey paper, it often happens, that a part of its substance is dissolved by their action, so that the filtered liquid is not so pure as we should wish to have it. This inconvenience, which is not equally perceptible when we use the *papier Joseph* in preference, may be still more diminished by the precaution of not employing filters till after they have previously been washed several times with boiling water. A careful preparer of medicines ought always to keep a store of filters washed in this manner, in order that he may be able to use them as occasion requires. *Josse*, a man of distinguished merit in pharmacy, to whom we are indebted for many important observations, has found their advantages in a variety of circumstances. He has remarked, amongst others, that whey, clarified and filtered through *papier rasin*, could be kept in good preservation for more than a fortnight, when filtered every day; which was not the case with the ordinary grey paper, though previously washed.

"By a diametrically opposite effect, different vegetable juices have been kept transparent and in good preservation, without passing into the acid state, by filtering them every day through grey paper: it has only been observed, that their colour became more intense during the first days, and that they afterwards gradually became colourless.

"But if the nature of filters demands our consideration, their form and position are no less deserving of our attention. In order that a filter of paper may produce its full effect, it is necessary that it should not adhere at all points to the substance which supports it; otherwise the filtration would soon be interrupted. This inconvenience is avoided by folding it different ways; but as these folds soon become deranged, some prefer placing straw, or glass tubes, between the filter and the

support. I confess that this latter expedient has not always succeeded with me, and that I have mostly remarked, that the folds made in the filters produced as much effect as the straw and tubes. In Germany, they use, for this purpose, funnels grooved on their inner surface.

"A period arrives, at which, whatever precautions may have been taken, the filtration grows languid, and at length is entirely suspended; this circumstance takes place, when the pores of the paper are obstructed in such a manner as no longer to afford a passage to the fluid. Sometimes we may prolong the filtration, by giving a slight circular motion to the funnel; but this effect is of short duration, and nothing more is left for us to do than to change the filter. It appears that no means have hitherto been discovered for remedying this inconvenience, to which all kinds of filters are liable.

"It has been already observed, that filters of woollen cloth, linen, and carded cotton, are also in use; those of woollen cloth were formerly very much in use; they are even the first that were employed; they were made in the form of a cone, the base of which was kept open by means of a ring, which was afterwards fastened to a frame with strings. This species of filter was termed the bag of Hippocrates; it is still used for filtering spirituous compounds. As it may be made very capacious, it is able to receive a large quantity of liquid at once, but it passes through very slowly; often even it is necessary to wait for a long time before the liquid passes through clear, on which account one ought never to have recourse to it, unless when others cannot be procured.

"However, when syrups are to be filtered, woollen cloth is used; but then, instead of giving it the form of a bag, the cloth is merely fixed upon a square frame, to which it is attached at its four corners by means of pegs. The boiling syrup is poured upon the middle of it, which almost always bags a little, and often at the end of a few minutes the liquor passes through very clear.

"This filter thus disposed may still be employed for filtering many other liquids, especially such as are of a watery nature, and do not contain pot-ash or soda in solution; for, were they never so slightly alkaline, the filter would soon be destroyed, and the filtered liquid would not possess the requisite qualities.

"Linen and paper are generally employed for filtering the alkaline liquids, and they answer the purpose very well, especially when these liquids are not too much concentrated.

"As to carded cotton, it is reserved for filtering such fluids as are considered precious, whether on account of the difficulty of procuring them, or of the small quantity with which one is provided.

"In order to form this filter, carded cotton is introduced into the tube of a glass funnel, and stuffed in with a rod of glass, so that it forms a kind of cork slightly compressed: the fluid which we wish to filter is then poured into the funnel. The filtration takes place drop by drop, and after the first have been separated, those which follow are always clear. The essential oils may very conveniently be filtered by this means, without danger of waste, which would inevitably take place if any of the other filters, of which I have already spoken, were used.

"The acids, especially those that are in a concentrated state, can only be filtered through pounded glass; but we must use the precaution not to employ this substance till after we have washed it several times, at first with a large quantity of water, and afterwards with an acid, in order to deprive it of the earthy or other foreign particles that might be dissolved by the acids which we wish to filter.

"The filters of glass may very well be formed in a funnel.

The great art that is required in order that they may produce this effect, is first to fix some fragments of glass in the tube, afterwards to add other smaller ones, and thus to continue, always diminishing the size of the fragments, till we have formed a thickness of three or four fingers' breadths, the upper layer of which ought to be glass reduced to fine powder.

"This kind of filter lets the liquid pass through with sufficient facility, that in less than an hour it is possible to filtrate several kilogrammes of acid, in a funnel of glass of a moderate size.

"Sand is also very commonly used for clarifying the water employed for domestic purposes. The cisterns lined with sand are in fact real filters, the effect of which is the more certain, the more the layers of sand are disposed in such a manner, that the water which covers them is obliged successively to pass through them, and that they retain the substances which injure its transparency.

"The art of constructing cisterns lined with sand has not yet arrived at the degree of perfection to which it might be brought, and though its object may seem to be of but small importance, it nevertheless well deserves the attention of philosophers.

"For the rest, experience proves that cisterns lined with sand can be used with advantage only during a certain time; frequently it is necessary to renew the sand which they contain, or at least to wash it, in order to deprive it of the earthy and heterogeneous substances which the water deposits in it, and which, when they have accumulated to a certain degree, not only prevent the filtration, or render it incomplete, but also communicate to the liquid a taste, which is the more disagreeable the longer they have remained in it.

"Nothing is more easy, as is well known, than to deprive the water of rivers of the earth which it often carries along with it, and which impairs its transparency. All that is required, is to let it stand for some hours in an earthen vessel, but uncovered, for the action of the air is necessary in order to effect this precipitation in a speedy and complete manner.

"However, though the practice of filtering water destined to be used as drink is to be traced to the most remote antiquity, it must be confessed, that the cisterns established for this purpose do not only free them of the mud which rendered them turbid, but likewise deprive them of a superabundance of air with which they are sometimes impregnated, a superabundance which constitutes their lightness, their sharpness, &c. in a word, that superiority which the water of the Seine, for example, has over that of all known rivers. The proof that this is the case, is that by dint of repeated filtrations one may render water insipid, heavy, and unwholesome.

"Thus when one wishes to determine the specific gravity of the water of the Seine, one ought to take it from the river on a day when it is limpid, or at least let it clear itself by standing, and not choose the filtered water in preference; for if this operation renders water more clear, it at the same time produces considerable changes in it, by depriving it, as has been remarked, of the air which it contains in superabundance.

"I have known a person whose organs of taste were rendered so acute by exercise, that he could distinguish water that had been filtered through sand from such as had not, by the different impressions which that made upon them. The latter appeared to him to be more rapid and light. This undoubtedly proceeds from the absence of the air we have mentioned, and which may be still more distinctly perceived under the recipient of the pharmaceutical apparatus. Some persons, interested in supporting the opinion contrary to that which has been advanced above, have asserted that if the water were continually obliged to pass through ten feet of sand and gravel from below upwards, it would be in a condition to produce,

with the weight of the heterogeneous substances, an effect capable of contributing to purify it completely, that is to say, to deprive it of its salts: the prepossession was so great that the following reasoning was adduced in favour of this notion.

"If these filters are sufficient for depriving the water of its air, why should not this operation of filtration be equally proper for depriving it of the salts which it contains? but attention has not been paid to the circumstances that these salts, held in solution in the water, being of greater specific weight, filter themselves together with it through the smallest tubes, whilst the air, being specifically lighter than the water, and existing in it in a state different from that of the salts, separates itself easily; finally, it has also been attempted to apply filtration to the water of the sea, with a view to render it palatable; the process for this purpose has been announced to government as a new and ingenious invention; it consisted in a filtration which was effected from below upwards by the application of force.

"But the union of the saline substances with the water is not a mere mechanical state of division; they are not merely interposed between its particles, as some philosophers have maintained, but they are perfectly dissolved in the water, and possess a degree of fluidity equal to its own. These salts consequently become capable of passing through filters with the most minute pores. It is therefore only by reducing the water to the state of vapours that we can separate the saline substances which it holds in solution, and no other expedient than distillation will ever produce a satisfactory effect. But let us resume the subject of the general effects of filtration.

"Besides the filters of which we have already treated, the stones known by the appellation of filtering-stones are also employed for clarifying water. Of these there are several kinds; they are very porous, as they consist for the greater part of free-stone. They are hollowed out and filled with water. This fluid gradually insinuates itself amongst their pores, and appears on the outside in the form of clear drops, which fall into a receptacle upon which the stones are placed.

"These stones ought previously to be washed several times with water; it is even remarked, that the water which is filtered through them during the first days has a disagreeable taste, which depends upon the foreign substances this fluid has dissolved in passing through the stone; so that it is not till the water which passes through has no longer any peculiar taste that it is fit to be used for drink.

"Upon the whole, the filtering-stone, as it has been extolled, is a bad means for procuring good water. Besides, the filtration proceeds very slowly, and frequently even ceases to take place, unless we use the precaution of rubbing both the inside and outside of the stone, from time to time, with a hard brush, in order to detach the mud which the water deposits upon it. It is undoubtedly to these inconveniences that we ought to attribute the disrepute into which this kind of filtration stands at present.

"It now only remains for us to speak of the processes employed, in order to give different fluids that perfect limpidity, which they can never acquire by spontaneous clarification and by means of filters, of whatever kind they may be.

"If it be true, that the opacity observable in certain fluids is entirely owing to the interposition of molecules which are not dissolved, but merely suspended in them by the aid of a state of extreme division, it is certain also, that under other circumstances the deficiency of transparency depends entirely upon the imperfect solubility of one or more substances which these fluids contain; so that in order to give them the desired limpidity, it is absolutely necessary to have recourse to means which augment the solubility of the substances in question, or at least effect their total separation.

"Albuminous and gelatinous matter, the acids, certain salts, lime, cream, blood, alcohol, may in many cases contribute to effect the clarification of certain fluids, for which the ordinary filters would be inadequate. However, these agents are not to be used indiscriminately, and the preference which is given to the one above the other always requires to be determined according to the knowledge which we have of the composition of the liquid we wish to clarify. Accident has discovered, for example, that two handfuls of marl, reduced to a coarse powder, and thrown into the pressing tub, clarify cider.

"The effect of the albuminous and gelatinous matters is principally remarkable in the vinous liquids. It is on this account that they are employed when it is required to fine wines, that is to say, when we wish to give them that high degree of limpidity which they can rarely acquire and preserve by mere repose. In this case, nothing more is required, than to dissolve either of these two substances in a small quantity of water, and to mix this solution cold with the wine; a short time after, a kind of net-work is observed throughout the whole mixture, which soon contracting together collects all the foreign substances from the wine, and carries them with it to the bottom of the vat.

"In other instances, one is obliged to heat the liquids with which we mix the albuminous matter; and it is only at the moment of ebullition that the clarification takes place. The most of the syrups are clarified by this process, and no other has yet been discovered that produces a better effect.

"It is also observed, that albuminous matter alone is not always sufficient to clarify liquids, even though we raise them to a degree of temperature sufficient to make them boil, but that it is necessary to assist its operation by means of an acid, or a salt with a redundancy of acid. In proof of this, we may adduce what takes place in the clarification of whey.

"In fact, it is demonstrated that it is only when we add to this fluid, at the moment when it begins to boil, some acidulous tartarite of potash (*cream of tartar*), or vinegar, that the albuminous matter with which it had previously been mixed, coagulates and carries with it the caseous matter, which impaired the transparency of the serum.

"For the rest, it is easily conceived that the quantity of acid which it will be proper to add in this case, must always bear a relation to the state of the fluid, and that it would be ridiculous to pretend that the proportion can be fixed in an invariable manner.

"New cream is employed with advantage for clarifying spirituous liquors: one or two spoonfuls to the pint are sufficient to produce this effect in the space of a few hours in the cold. But as in this clarification, some caseous particles always remain suspended in the fluid, by reason of their great tenacity, it is necessary to separate them at last by filtration through a bag or through paper.

"Finally, there are some fluids, which, in order to become clear, require to be subjected to a degree of heat nearly approaching that of boiling water. These are principally such as are rendered opaque merely by substances, the solubility of which cannot become complete, unless it be facilitated by raising the temperature of their solvent above its natural rate. Many saline solutions stand in this predicament, and whoever occupies himself ever so little with chemistry, will frequently meet with such.

"Most of the fresh-expressed juices of vegetables may also be partially clarified by the operation of heat. Thus it is customary amongst apothecaries to have recourse to this means with those juices which, on account of their thickness and viscosity, are not susceptible of being filtered.

"Frequently a slight degree of heat, applied to the expressed

and filtered juices of certain vegetables, is sufficient suddenly to destroy their transparency; in this case a flaky whitish substance floats in the liquid, and collects at the bottom of the vessel. This is the substance which Rouelle, the younger, considered as the vegeto-animal matter of corn, and which I demonstrated, as far back as the year 1772, to be nothing more than a substance analogous to the white of egg; which proves that at that period we were upon the way to inscribe albumen amongst the products of the vegetable kingdom.

"An important observation, upon which I ought to insist, is, that in general it appears absolutely necessary to separate the *magma*, which forms in liquors that are clarified with albuminous matter, especially when, in order to concentrate those liquids, it is necessary to evaporate them by the aid of ebullition. Without this precaution, this *magma* would dissolve, and the liquors would become more turbid than they were previous to the clarification. It proceeds from a similar cause, that broth, from which the scum has not been taken off, always retains a disagreeable appearance, and will not keep.

"Though the employment of albuminous matter for clarifying the juices of certain vegetables be of utility, it is, however, not without its inconveniences. Amongst others, one that has been remarked is, that it changes the nature of these fluids in such a manner, as partly to destroy their medicinal properties. It is known what happens to certain pharmaceutical preparations, such as decoctions of medicines, when, in order to clarify them, recourse has been had to white of egg and heat; for then they are almost without effect, unless we take care to double the proportions of the ingredients that ought to enter into their composition. Lewis has remarked that this operation deprived the syrup of diacodium of all its powers.

"These are the observations which I thought would be useful to collect on the subject of clarification. My intention in communicating them was to shew, that such an operation, though simple in appearance, must not be performed in an indifferent manner, and that, amongst the various processes that are in common use, some do not present results equally satisfactory with those of others. The choice ought therefore always to be determined according to the nature of the substances upon which we have to operate. I confine myself to the relation of the facts; to others I leave it to give the explanations of them that may be desired."

DEFESCH (William), a German, and some time chapel-master at Antwerp, was in his time a respectable professor on the violin, and leader of the band for several seasons at Marybone-Gardens. His head was engraved as a frontispiece to some musical compositions published by him, and his name is to be found on many songs and ballads to which he set the tunes for Vauxhall and Marybone-Gardens. He died about 1751, aged 70.

DEFORCEMENT, in Scots law, the opposing or resisting of the officers of the law in the execution of their office.

DEINSE, or DEYNSE, a town of Austrian Flanders, seated on the Lis, eight miles S.W. of Ghent. Long. 3. 39. E. Lat. 50. 59. N.

DEIZABAD, a town of Persia, in Irac-Agemi, ninety miles N. of Isfahan.

DELACOUR (James), an elegant, though neglected poet, was an inhabitant of Cork, in Ireland, and much cared for his sprightly wit and moral conduct, beauties which are very rarely united. His first published poem was entitled *The Prospect of Poetry*, inscribed to Boyle earl of Orrery, and introduced by complimentary verses from several respectable writers of the day. Though rather too impetuous and fiery (a sad prediction of his future destiny), it contains some pas-

pages, surprisingly beautiful and sublime; the measure is harmonious, the design uniform, though not new, and, altogether, it is a performance of infinite merit. His description of the birth of Love is replete with tender and elegant conception. Mr. Bell, in his compilation of *Fugitive Poetry*, has very judiciously retained, indeed, we may say, revived this piece.

His *Progress of Beauty*, which is, we suppose, very scarce in this kingdom, is far superior to Lord Lansdowne's on the same subject, and with the same title. His *Epithalamium*, also, has all the delicacy and sweetness of Catullus. But, alas! all human endowments are variable, and the page of this day has often been the ideot of the next.

Poor *Delacour*, at an earlier age than his unrivalled countryman *Swift*, was a member of society no more. All his once vivid faculties were fled, and all his myrtles blasted. We assign him the myrtle, because like *Lee*, who lost his reason also, his chief talent lay in chaste amorous description. He was frequently seen in the open street, with a mob of boys around him, pouring forth extempore rhymes, chiefly satirical; not unfrequently exhibiting some bright, but evanescent, flashes of fancy amidst his wildest delirium!

Even during the long period of *Delacour's* infamy, the light of the poet was not totally extinguished: there exists a manuscript copy of his *Verbes* on the Earthquake at Lisbon, composed in some serene moment, full of lofty, but extravagant conception. And he produced about the same time some little pieces, which appeared in the *Gentleman's Magazine*, then the repository of wit and genius; and, in particular, some lines to the author of the *Seasons* (which inspired even the leaden pen of old Dennis the critic); and an humorous epitaph on a tallow-chandler, who bequeathed ten pounds to reward the best tribute to his memory.

DELEBIO, a town of Switzerland, in the Valteline, on a small river which runs into the *Adda*, five miles N.W. of *Morbegno*.

DELFINO, a town of Turkey in Europe and capital of Lower Albania, where the pacha resides. It is fifty miles E.N.E. of *Larida*.

DELFTSHAVEN, a fortified town of Holland, on the N. side of the Meuse, with a canal to *Delft*, &c. It is between *Rotterdam* and *Schiedam*, not three miles from either.

DELFTZUYL, a fortress of the United Provinces, in Groningen. It was taken by the Spaniards in 1581, and retaken by the Dutch in 1590. It is seated on the *Damster*, thirteen miles N.E. of Groningen.

DELICHI, a river of Albania, the *Acheron* of the ancient poets, who feigned it to be in hell.

DELICT, in Scots law, signifies such small offences or breaches of the peace as are punishable only by fine or short imprisonment.

DELLAMCOITA, a fortress of the country of Bootan, which commands the principal pass over the mountains. It was taken by storm in 1773, by a detachment under the command of Captain John Jones, and is 175 miles N. of *Moorshedabad*.

DELOS (*Encycl.*). Anciently this island was governed by its own kings. *Virgil* mentions one *Anius* reigning here in the time of the Trojan war. He was, according to that poet, both king and high-priest of *Apollo*, and entertained *Aeneas* with great kindness. The Persians allowed the Delians to enjoy their ancient liberties, after they had reduced the rest of the Grecian islands. In after ages, the Athenians made themselves masters of it; and held it till they were driven out by *Mithridates the Great*, who plundered the rich temple of *Apollo*, and obliged the Delians to side with him. *Mithridates* was in his turn driven out by the Romans, who granted the inhabitants many privileges, and exempted them from all

sorts of taxes. At present it is quite abandoned; the lands being covered with ruins and rubbish, in such a manner as to be quite incapable of cultivation. The inhabitants of *Mycone* hold it now, and pay but ten crowns land-tax to the grand-signior for an island which was once one of the richest in the world.—*Strabo* and *Callimachus* tell us that the island of *Delos* was watered by the river *Inäpus*: but *Pliny* calls it only a spring; and adds, that its waters swelled and abated at the same time with those of the Nile. At present there is no river in the island, but one of the noblest springs in the world; being twelve paces in diameter, and inclosed partly by rocks, and partly by a wall. Mount *Cynthus*, whence *Apollo* had the surname of *Cynthius*, is by *Strabo* placed near the city, and said to be so high, that the whole island was covered by its shadow; but our modern travellers speak of it as an hill of a very moderate height. It is but one block of granite of the ordinary sort, cut, on that side which faced the city, into regular steps, and inclosed on both sides by a wall. On the top of the mountain are still to be seen the remains of a stately building, with a mosaic pavement, many broken pillars, and other valuable monuments of antiquity. From an inscription discovered there some time ago, and which mentions a vow made to *Serapis*, *Isis*, and *Amubis*, some have conjectured, that on this hill stood a temple dedicated to these Egyptian deities, though no-where mentioned in history.—The city of *Delos*, as is manifest from the magnificent ruins still extant, took up that spacious plain reaching from one coast to the other. It was well peopled, and the richest city in the Archipelago, especially after the destruction of *Corinth*; merchants flocking thither from all parts, both in regard of the immunity they enjoyed there, and of the convenient situation of the place between Europe and Asia. *Strabo* calls it one of the most frequented empories in the world; and *Pliny* tells us, that all the commodities of Europe and Asia were sold, purchased, or exchanged there. It contained many noble and stately buildings; as, the temples of *Apollo*, *Dianna*, and *Latona*; the porticoes of *Philip* of Macedonia, and *Dionysius Eutyches*; a gymnasium; an oval basin made at an immense expence, for the representation of sea-fights; and a most magnificent theatre. The temple of *Apollo* was, according to *Plutarch*, begun by *Eryfichton* the son of *Cecrops*; but afterwards enlarged and embellished at the common charges of all the states of Greece. *Plutarch* tells us, that it was one of the most stately buildings in the universe; and speaks of an altar in it, which, in his opinion, deserved a place among the wonders of the world. It was built with the horns of various animals, so artificially adapted to one another, that they hanged together without any cement. This altar is said to have been a perfect cube; and the doubling it was a famous mathematical problem among the ancients. This went under the name of *Problema Deliacum*; and is said to have been proposed by the oracle, for the purpose of freeing the country from a plague. The dispenser was to cease when the problem was solved.—The trunk of the famous statue of *Apollo*, mentioned by *Strabo* and *Pliny*, is still an object of great admiration to travellers. It is without head, feet, arms, or legs; but from the parts that are yet remaining, it plainly appears, that the ancients did not exaggerate when they commended it as a wonder of art. It was of a gigantic size, though cut out of a single block of marble; the shoulders being six feet broad, and the thighs nine feet round. At a small distance from this statue lies, amongst confused heaps of broken columns, architraves, bases, chapters, &c. a square piece of marble 15½ feet long, ten feet nine inches broad, and two feet three inches thick; which undoubtedly served as a pedestal for this colossus. It bears, in very fair characters, this inscription in Greek, "The Naxians to *Apollo*." *Plutarch* tells us, in the life of *Nicias*, that he

caused to be set up, near the temple of Delos, an huge palm-tree of brass, which he consecrated to Apollo; and adds, that a violent form of wind threw down this tree on a colossian statue raised by the inhabitants of Naxos. Round the temple were magnificent porticoes built at the charge of various princes, as appears from inscriptions which are still very plain. The names of Philip king of Macedon, Dionysius Eutyches, Mithridates Evergetes, Mithridates Eupator, kings of Pontus, and Nicomedes king of Bithynia, are found on several pedestals.—To this temple the inhabitants of the neighbouring islands sent yearly a company of virgins to celebrate, with dancing, the festival of Apollo and his sister Diana, and to make offerings in the name of their respective cities.

DELRIO (Martin Anthony), a most learned man, was born at Antwerp of Spanish parents, in 1551. The progress he made in letters, while a very boy, is recorded with wonder. He was taught grammar in the Low-countries; and then sent to Paris to learn rhetoric and philosophy under the Jesuits. Afterwards he went to study civil law in the new university of Douay; but removing from thence to Louvain, he laid aside that pursuit, and applied himself to polite literature. This he cultivated with so much ardour and success, that he surprised the public, when he was only nineteen years of age, with some good notes upon the tragedies of Seneca. He cited in this work almost 1100 authors, with all the assistance of a man who had read them thoroughly, and weighed their sentiments with great judgment and exactness. The reputation he acquired by this first essay of his erudition was afterwards increased. He is said to have understood at least ten languages, and to have read every thing, ancient or modern, that he thought worth reading. He was admitted LL. D. at Salamanca in 1574; and was afterwards a counsellor of the parliament of Brabant, and an intendant of the army. In 1780 he became a Jesuit at Valladolid; from whence, going into the Low-countries, he taught divinity and the belles-lettres, and contracted a firm friendship with Lipsius. He taught also at Liege, at Mayence, at Gratz, and at Salamanca. He died at Louvain, in 1608, about two years after his friend Lipsius.

Besides notes upon Seneca, Claudian, and Solinus, he wrote a great number of works, the principal of which are, 1. *Dquisitiones Magice*. 2. *Commentaries upon some Books of the Old Testament*. 3. *Explications of some of the hardest and most important Texts of Scripture*. We must not confound him with John Delrio, of Bruges, dean and grand vicar of Antwerp, who died in 1624; and who was the author of *Commentaries upon the 119th Psalm*.

DELSPERG, a town of Switzerland, in the bishopric of Basle, ten miles N.W. of Soleure. Long. 7. 23. E. Lat. 47. 17. N.

DEMBEA, a considerable lake of Abyssinia, in a province of the same name, in the W. part of the empire. It is supposed to be 450 miles in circumference, and contains many islands, one of which is a place of confinement for state prisoners.

DEMER, a river which rises in the bishopric of Liege, waters Hasselt, Dieft, Sichern, Archot, and Mechlin, below which it joins the Senne, and takes the name of Rupe.

DEMERARY, a Dutch settlement in Guiana, on a river of the same name, three leagues W. of Paramaribo. It was taken by the English in 1781; but the French dispossessed them of it soon after, and by the treaty of peace in 1783, it was restored to the Dutch. It was again taken by the English in April 1796.

DEMMIN, an ancient town of Swedish Pomerania, in the duchy of Stettin, on the river Peen. Long. 13. 22. E. Lat. 53. 52. N.

DE MISSY (Cæsar), a man greatly distinguished in the learned world, though no great author in form, was born at Berlin, Jan. 2, 1703, being the son of a merchant there. He studied first at the French college at Berlin, and thence removed to the university of Francfort on the Oder. He was examined for the ministry in 1725, and after some difficulties obtained it; but the ecclesiastics there being hampered with subscriptions, to which he could not assent, he quitted the country soon after. He preached about five years in different towns of the United Provinces, from whence he was invited to London in 1731, and ordained to serve the French chapel in the Savoy. In 1762 he was named by the Bishop of London to be one of the French chaplains to the king in his chapel at St. James's. He died August 10, 1775. He seldom published any thing except occasionally, in consequence of unforeseen engagements, or at the importunity of friends. Several little poetical pieces, essays both in sacred and profane literature, epitomes of books, memoirs, dissertations, &c. by De Missy, with his initials C. D. M. or some assumed name, and frequently anonymous, appeared in different collections and periodical journals in Holland, France, and England, from 1721. He was greatly assisting to many of the learned in their several undertakings: among others who are indebted to him, were the late Professor Wetstein, in his splendid edition of the Greek Testament, and the late Dr. Jortin, in his *Life of Erasmus*. He was twice married, but left no child.

DEMONA, a fort of Piedmont, on the river Stura, ten miles S.W. of Coni. Lon. 7. 28. E. Lat. 44. 18. N.

DEMOTICA, or DYMOTEC, a town of Turkey in Europe, in Romania, where a Greek archbishop resides. It was the residence of Charles XII. for some years; and is situate near the Maritich, twelve miles S. of Adrianople.

DEMPSTER (Thomas), a very learned man, but of a singular character. He was born in Scotland, but we do not find in what year. He went over to France, for the sake of embracing the catholic religion; and taught classical learning at Paris about the beginning of the seventeenth century. Though his business was to teach school, yet he was as ready to draw his sword, and as quarrelsome, as if he had been a duellist by profession: and it is said, that there scarce passed a day but he had something or other of this kind upon his hands. This spirit and turn of temper drew him into many scrapes; and one in particular, which obliged him to quit the country. Grangier, principal of the College of Beauvais at Paris, being obliged to take a journey, appointed Dempster his substitute. Dempster caused a scholar to be whipped in full school, for challenging one of his fellows to fight a duel. The scholar, to revenge this affront, brought three gentlemen of his relations, who were of the king's life-guards, into the college. Dempster made the whole college take arms; hamstringing the three life-guard men's horses before the college gate; and put himself into such a posture of defence, that the three sparks were forced to ask for quarter. He gave them their lives; but imprisoned them, and did not release them for some days. They sought another way to revenge themselves: they caused an information to be made of the life and moral behaviour of Dempster, and got some witnesses to be heard against him. Upon this he went over to England, where he found refuge; but did not make any long stay. He went abroad again, and read lectures upon polite learning in several universities; in that of Nismes particularly, where he disputed for a professor's chair, and obtained it. He went to Bologna, and was professor there for the remainder of his life; and was then also admitted a member of the Academy della Rotte. He died there in September 1625, leaving behind him several learned works; as *Commentaries on Rofinus de Antiquitatibus Romanorum*, and upon Claudian, &c.; four

books of Epistles; several dramatic pieces, and other poems; some books of law; an Apparatus to the History of Scotland; a Martyrology of Scotland; and a List of the Scottish Writers.

DENAIN, a village of France, in the department of the North, remarkable for a victory gained over Prince Eugene, by Marshal Villars, in 1712. It is seated on the Scheldt, eight miles W. of Valenciennes.

DENDER, a river of Austrian Hainault, which waters Leuze, Ath, Lefines, Grammont, Ninove, and Aloft, and joins the Scheldt at Dendermonde.

DENDERA, a town of Egypt, on the W. side of the Nile. Near it are very magnificent ruins, supposed to be those of an ancient temple of Serapis. It is 48 miles S.S.E. of Girge, and 242 S. of Cairo. Long. 31. 40. E. Lat. 26. 10. N.

DENDRANATOMY, a term used by some for a description of the various parts of trees; as root, trunk, branch, bark, wood, pith, flower, fruit, &c. See **PLANTS, VEGETATION, &c.**

DENIA, an ancient sea-port of Spain, in Valencia, on the Mediterranean Sea, and at the foot of a mountain, 52 miles E. of Alicante. Long. 0. 36. E. Lat. 38. 44. N.

DENMARK (*Encycl.*). The laws of Denmark are so concise, that the whole body is contained in one quarto volume, written in the language of the country. Every man may plead his own cause, without employing either council or attorney: but there are a few advocates for the benefit of those who cannot or will not speak in their own defence. The proceedings are so summary, that a suit may be carried through all the courts, and finally decided, in thirteen months. There are three courts in Denmark, and an appeal lies from the inferior to the superior tribunal. The lowest of these is, in cities and towns, denominated the *Byfogeds Court*; and in the country, the *Herredsfoogds*. Causes may be appealed from this to the *Landfog*, or general head-court for the province: but the final appeal lies to the court of *High-right* in Copenhagen, where the king presides in person, assisted by the prime nobility. The judges of the two other courts are appointed by his majesty's letters patent, to sit and determine causes *durante bene placito*. These are punishable for any misdemeanours of which they may be guilty; and when convicted of having passed an unjust sentence, they are condemned to make reparation to the injured party. Their salaries are very inconsiderable, and paid out of the king's treasury, from the fines of delinquents, besides a small gratuity from the plaintiff and defendant when sentence is passed: Such is the peculiar privilege enjoyed by the city of Copenhagen, that causes appealed from the *Byfogeds* court, instead of passing through the provincial court, are tried by the burgomaster and common-council; from whence they proceed immediately to the highest court, as the last resource. Affairs relating to the revenue are determined in the rent-chamber of Denmark, which is analogous to our court of exchequer. To another tribunal, composed of some members from this rent-chamber, from the admiralty, and college of commerce, merchants appeal for redress, when their commodities are seized for non-payment of duties. All disputes relating to the sea are determined by the court of admiralty, constituted of commissioners appointed for these purposes. The chancellor may be more properly termed a secretary's office. It consists of clerks, who write and issue all the king's decrees and citations, transcribe papers, and, according to the directions they receive, make draughts of treaties and alliances with other nations. The government of Denmark is very commendable for the excellent policy it maintains. Justice is executed upon criminals with great severity; and such regulations are established as effectually prevent those outrages that are daily committed in other coun-

tries. No man presumes to wag his tongue against the government, far less to hatch schemes of treason. All the subjects are, or seem to be, attached to their sovereign by the ties of affection. Robbery on the highway, burglary, coin-ing or clipping, are crimes seldom or never heard of in Denmark. The capital crimes usually committed are theft and manslaughter. Such offenders are beheaded very dexterously with one stroke of a sword. The executioner, though infamous, is commonly rich; because, over and above the functions of his office, he is employed in other scandalous occupations, which no other person will undertake. He, by means of his understrapper, called the *pracher*, empties all the jakes, and removes from houses, stables, or streets, dead dogs, horses, &c. which no other Dane will vouchsafe to touch on any consideration whatsoever.

In Copenhagen there is a master of the police, who superintends the economy of that city. No torches are allowed to be carried through the streets of this city, because great part of the houses are of timber, and the wind is generally high. In lieu of *fixembaux*, the court and quality use large round lanterns, flamed to the end of long poles. In a word, the master of the police regulates every thing that relates to the decency, good order, quiet, and security, of the capital. The apothecaries in this kingdom are under excellent regulations: their number at Copenhagen is restricted to two; and one is allowed to every other town of importance. They are examined and appointed by the college of physicians, and confirmed by the king himself; otherwise they cannot exercise the profession. Their shops are visited three times a-year by the magistrates, accompanied with physicians, who inspect their medicines and regulate the prices. They are obliged to keep an exact account of every thing they sell, to specify the name of the person who bought it, and that of the doctor by whom it was prescribed; so that accidents are prevented, and murders by poison easily discovered.

DENNIS, or **St. DENNIS**, a famous town of the Isle of France, with a Benedictine abbey, wherein are the tombs of the kings of France, with a considerable treasure. E. Long. 2. 26. N. Lat. 48. 56.

DENYS (the Little), a Scythian, became abbot of a monastery at Rome: he was the first who computed time from the birth of Dionysius to Christ, and fixed that great event, according to the vulgar æra. He was also a learned canon-law writer, and died about the year 540.

DEPURATION. See **DEFECATION** in this SUPPLEMENT.

DERENBURG, a town of Lower Saxony, in the principality of Halberstadt, six miles W.S.W. of Halberstadt, and 17 E. of Gollar.

DEREOTE, or **DEIROUTE**, a town of Egypt, in the isle formed by the canal from Cairo to Rosetta. Here is a magnificent temple. Long. 31. 45. E. Lat. 30. 40. N.

DERHAM (William). (*Encycl.*). To our account of this excellent philosopher and divine, it may not be amiss to add a list of his works, most of them published in the *Philosophical Transactions*. 1. Part of a Letter dated Dec. 6, 1697, giving an Account of some Experiments about the Height of the Mercury in the Barometer at the Top and Bottom of the Monument in London; and also a Description of a portable Barometer. 2. A Letter dated Jan. 13, 1697-8, about a Contrivance to measure the Height of the Mercury in the Barometer, by a Circle, on one of the Weather Plates; with a Register or Diary of the Weather, observed every Day at Upminster, during the Year 1697. 3. A Letter to Dr. Sloane; with a Register of the Weather, Winds, Barometer's Height, and Quantity of Rain fallen at Upminster in Essex, during the Year 1698. 4. A Register, &c. as above, for the Year

2699. In these registers, he exhibits to view, in separate columns, every day, at the hours of eight, twelve, and nine, the weather; winds, clouds, height of the barometer, rain, &c. 5. Observations on the Death-Watch, or that Insect which makes a noise like the Beats of a Watch. 6. Observations on the Weather, Rain, Winds, &c. for 1699, 1700, 1701, 1702, compared with other Observations made at Townley in Lancashire, by Mr. Townley, and communicated to our Author. 7. An Account of some Spots observed in the Sun in June 1703. 8. Observations on the great Storm, Nov. 26, 1703. 9. The History of the Death-Watch: from which the Superstitious may learn, to the great Ease and Comfort of their Souls, that the tickling Noise of this minute Creature, which fills them with such Terrors and Forebodings, is nothing more than a wooling A&I, and commonly heard in July, or about the Beginning of August. 10. An Account of an Instrument for finding the Meridian, with a Description of the same. 11. Experiments on the Motion of Pendulums in vacuo. 12. A Prospect of the Weather, Winds, and Height of the Mercury in the Barometer, on the first Day of the Month; and of the whole Rain in every Month in 1703, and the Beginning of 1704: observed at Townley in Lancashire, by R. Townley, Esq. and at Upminster in Essex, by our Author. 13. An Account of a Glade of Light seen in the Heavens, March 20, 1704-6. 14. Tables of the Weather, &c. for 1705. 15. An Account of a pyramidal Appearance in the Heavens, seen in Essex, April 3, 1707. 16. Experiments and Observations on the Motion of Sound; in Latin. 17. On the Migration of Birds. 18. An Account of an Eclipse of the Sun, Sept. 5, 1708, as observed at Upminster: and of an Eclipse of the Moon, Sept. 18, 1708. 19. An Account of a strange Meteor, or Aurora Borealis, in Sept. or Oct. 1706. 20. An Account of a Child crying in the Womb. It was the child of one Clark, of Horn Church in Essex, who was heard to cry in his mother's womb, at times, for five weeks. 21. The History of the great Frost in 1708. 22. Account of Spots observed in the Sun by our Author, from 1705 to 1708; and from 1707 to 1711. 23. Of subterraneous Trees found at Dagenham-Breach in Essex. 24. Account of an Eclipse of the Moon, seen at Upminster, Jan. 12, 1711-12. 25. Of a Woman big with Child, and having the Small-pox, delivered of a Child having the same Distemper, Sept. 8, 1713. 26. An Account of the Rain at Upminster, for eighteen Years. 27. Tables of the barometrical Altitudes for 1708, at Zurich in Switzerland; and of the Rain of Pisa in Italy, and Zurich, and Upminster, for 1707, 1708: with Remarks on the Winds, Heat and Cold, &c. 28. Miscellanea occasioned by swallowing the Stones of Bullace and Sloes. 29. Extract from Mr. Gassaigne's and Mr. Crabtree's Letters, proving Mr. Gassaigne to have been the Inventor of the telescopic Sights of Mathematical Instruments, and not the French. 30. Observations about Wasps, and the Difference of their Sexes. 31. Observations on the Lamen Boreale, or Streaming, Oct. 8, 1725. 32. Tables of the Eclipses of Jupiter's Satellites, from 1700 to 1727; with Remarks on those Tables. 33. The Difference in Time of the Meridians of divers Places, computed from Observations on the Eclipses of Jupiter's Satellites. 34. A Letter to Sir Hans Sloane, Bart. containing a Description of some uncommon Appearances, observed in an Aurora Borealis, Oct. 13, 1728. 35. Of the Meteor called the Ignis Fatuus, from Observations made in England by our Author, and others in Italy, communicated by Sir Thomas Derham, Bart.

He published in his younger years, The Artificial Clock-Maker; or, a Treatise of Watch and Clock Work, shewing to the meanest Capacities the Art of calculating Numbers to all Sorts of Movements; the Way to alter Clock-Work; to

make Chimes, and set them to musical Notes; and to calculate and correct the Motion of Pendulums. Also, Numbers for divers Movements; with the ancient and modern History of Clock-Work; and many Instruments, Tables, and other Matters, never before published in any other Book. The fourth edition of this book, with large emendations, was published in 1734, 12mo. In 1711 and 1712 he preached sixteen sermons at Boyle's Lectures; which, having put into a new form, he published in 1713, under this title, Physico-Theology; or, a Demonstration of the Being and Attributes of God from his Works of Creation: with large Notes, and many curious Observations, 8vo. And, in pursuance of the same design, he published, in 1714, Astro-Theology; or, a Demonstration of the Being and Attributes of God from a Survey of the Heavens. Illustrated with copper-plates, 8vo. In 1716 he was made a canon of Windsor, being at that time chaplain to the Prince of Wales; and, in 1730, received the degree of D.D. from the university of Oxford, on account of his learning, and the services he had done to religion by his culture of natural knowledge. When Eleazar Albin published his Natural History of Birds, and English Insects, in 4 vols. 4to, with many beautiful cuts, it was accompanied with very curious notes and observations by our learned author. He also revised the Miscellanea Curiosa, published in 3 vols. 8vo. 1726. The last thing he published of his own composition was, Christo-Theology; or, a Demonstration of the Divine Authority of the Christian Religion, being the Substance of a Sermon preached at Bath, Nov. 2, 1729, and published at the earnest Request of the Auditory, 1730, 8vo. But, besides his own, he published some pieces of Mr. Ray, and gave new editions of others, with great additions from the author's own MSS. To him the world is likewise indebted for the publication of the Philosophical Experiments and Observations of the late eminent Dr. Robert Hooke, and other eminent Virtuoses in his Time, 1726, 8vo, with copper cuts. He communicated also to the Royal Society several pieces, which he received from his learned correspondents.

DERNE, a town of Barbary, capital of a district in Tripoli, near the coast, and the residence of a sangiac. Long. 22. 45. E. Lat. 32. 55. N.

DERRICK (Samuel), a native of Ireland, was born in 1724. Being intended for trade, he was some time placed with a linen-draper in Dublin, but disliking his business, he quitted it and his country about 1751, and commenced author in London. Soon after he arrived at the metropolis, he indulged an inclination which he had imbibed for the stage, and appeared in the character of Gloucester, in *James Shore*; but with little success, that he never repeated the experiment. After this attempt he subsisted chiefly by his writings, but being of an expensive disposition, running into the follies and excesses of gallantry and gaming, he lived almost all his time the slave of dependence, or the sport of chance. His acquaintance with people of fashion, on Beau Nash's death, procured him at length a more permanent subsistence. He was chosen to succeed that gentleman in his offices of master of the ceremonies at Bath and Tunbridge. By the profits of these he might have been enabled to place himself with economy in a less precarious state; but his want of conduct continued after he was in the possession of a considerable income, by which means he was at the time of his death, March 7, 1760, as necessitous as he had been at any period of his life. He translated one piece from the French of the King of Prussia, called *Sylla*, a dramatic entertainment, 1753, 8vo.

DERWENT, a river of Derbyshire, which rises in the high Peak, flows S. through the middle of the county, and,

passing Derby, empties itself into the Trent, on the borders of Leicestershire.

DERWENT, a river of Yorkshire, which rises in the N. riding, and running S. falls into the Ouse, below York.

DERWENT, a river of Durham, which forms, for some space, the boundary between that county and Northumberland, and falls into the Tyne, above Newcastle.

DERWENT, a river of Cumberland, which, flowing through the lakes of Derwent-water and Bassenthwaite-water, to Cockermouth, enters the Irish Sea, near Workington.

DERWENT-WATER, a lake of Cumberland, in the vale of Kestwick. It is three miles in length, and a mile and a half wide. Five islands rise out of this lake, which add greatly to the beauty of the appearance. On one of them is an elegant modern-built house.

DES BARREAUX (James de Vallec, Lord), a French nobleman, and born at Paris in 1602, was, like the English Lord Rochester, a great wit, a great libertine, and a great penitent. He made a vast progress in his studies under the Jesuits, who, perceiving he had a genius capable of any thing, endeavoured to get him into their society; but neither he nor his family would ever listen to the proposal. He did not love them, and used to rail at them in an agreeable manner. He was intimate with Theophile, who was advocate-general, and afterwards president in the parliament of Paris; and, being very handsome in his youth, it is said that Theophile was in love with him, and sometimes even jealous of him. Some pretend, that he abused him; but Des Barreaux's friends have assured us, that he always abhorred that unnatural vice. He was very young when his father procured him the place of a councillor in the parliament of Paris. His wit was admired there, but he would never report a cause; for he used to say, that it was a sordid occupation, and unworthy of a man of parts, to read wrangling papers with attention, and to endeavour to understand them. He lost that place from the following cause:—Cardinal Richelieu falling in love with the celebrated beauty Marion de Lorme, whose affections were entirely placed on our Des Barreaux, proposed to him by a third hand, that if he would resign his mistress, he should have whatever he should desire. Des Barreaux answered the proposal no otherwise than in a jesting way; feigning all along to believe the cardinal incapable of so much weakness. This enraged the minister so highly, that he persecuted our councillor as long as he lived, and forced him not only to quit his place, but to leave the kingdom.

As Des Barreaux loved his liberty and his pleasures extremely, he did not find himself unhappy in having quitted the long robe. He made a great number of Latin and French verses, and some very pretty songs: and never pursued any thing but good cheer and diversions. He was vastly entertaining in company, and greatly sought after by all men of wit and taste. He had his particular friends in the several provinces of France, whom he frequently visited; for he took a pleasure in shifting his quarters, according to the seasons of the year. In winter, he went to seek the sun on the coasts of Provence. He passed three of the worst months in the year at Marseilles. The house which he called his favourite was that of the Count de Clermont de Lodeve, in Languedoc; where, he used to say, good cheer and liberty were on their throne. Sometimes he went to Balzac on the banks of the Charante; but his chief residence was at Chenailles, on the Loire. His general view in these ramblings was to search out the best fruits and the best wines in the climates; however, it must be observed, in justice to him, that the pleasures of the mind, as well as those of the body, were sometimes the occasion of his journeys; as, when he went into Holland, on

purpose to see Des Cartes, and to improve by the instructions of that great genius.

His friends do not deny that he was a great libertine; but pretend, that Fame, according to custom, has laid more of him than is true, and that, in the latter part of his life, he was convinced of the reality of religion. They say, that he did not disapprove the truths of Christianity, and wished to be fully convinced of them; but he thought nothing was so difficult to a man of wit as to believe. He was born a Catholic, but had not the least faith either in the worship or doctrines of the Romish religion; and he used to say, that if the Scriptures are the rule of our actions and of our belief, there was no better religion than the Protestant. However all this might be, it is certain that, four or five years before his death, he entirely forsook his vicious courses: he paid his debts, and, having never been married, gave up the remainder of his estate to his sisters; reserving to himself for life an annuity of 4000 livres. He then retired to Chalon, on the Soane, which he said was the best and purest air in France; hired a small house; and was visited by the better sort of people, particularly by the bishop, who afterwards spoke well of him. He died in that city, like a good Christian, in 1647, having made a devout sonnet two or three years before his death, which was greatly esteemed.

DESEADA, or CAEE DESIRE, the southern point of the straits of Magellan, in S. America, at the entrance of the S. Sea. Long. 74. 18. W. Lat. 53. 4. N.

DES MAIZEAUX (Peter), secretary of the Royal Society of London, was the son of a French Protestant minister, and born at Auvergne in 1666. He retired early, probably as a refugee, into England; and died there in 1745. He had intimate connections with St. Evremont and Bayle. He gave a very handsome edition of the works of the former, in 3 vols. 4to. with the life of the author prefixed: and he drew up the life of the latter, which was printed before the edition of his Dictionary, in 1730, and separately at the Hague, 1732, 2 vols. 12mo. He published also, in the same year, the Miscellaneous Works of Bayle, in 4 vols. folio. He was the editor of other things; and whatever he published he accompanied with remarks, full of literary anecdotes. He was very exact and curious in his accounts; but somewhat prolix and tedious.

DESTOUCHES (André, Cardinal), a French musician, was born at Paris in 1672. He accompanied Father Tachard to Siam, with a resolution of entering into the society of Jesuits upon his return; but he changed his purpose, and became a soldier. It was in this line of life that he discovered his talents for music; and he quitted soldiery, that he might devote himself entirely to it. He soon gained a vast reputation by his opera of *Lise*, which the king relished so highly, as to present the composer with 200 louis-d'ors; graciously adding, that no music since Lulli had pleased him so much as his. What was very singular is, that Destouches, when he made this charming piece, knew nothing of composition; but, instead of art, he had genius, and (what is usually the concomitant of genius) a very strong passion for his object. After producing the *Lise*, he made himself master of rules; but it is said, that they damped his genius, and that none of his compositions afterwards equalled the *Lise*. He died in 1749, superintendent of the royal band, and inspector-general of the royal academy of music, with a pension of 4000 livres.

DESTOUCHES (Philip Nericaut), a French dramatic writer, was born at Tours in 1680, and educated at Paris. His first destination was to the army; but he quitted this service, to attach himself to the Marquis de Puyfieux, ambassador of France with the Helvetic body. It was in Switzerland that his talent for theatrical productions first displayed itself; and

his *Curieux Impertinent* was exhibited there with applause. His dramatic productions made him known to the regent, who sent him to London in 1717, to assist, in his political capacity, at the negotiations then on foot. He spent seven years thus in London, married a wife, and returned to his country; where the dramatist and negotiator were well received. The regent had a just sense of his services, and promised him great things; but dying soon after, left Desfouches the meagre comfort of reflecting, how well he should have been provided for if the regent had lived. Having lost his patron, he retired to Fortlécq, near Melun, as the most proper situation to make him forget the caprices of fortune. He purchased the place; and, cultivating agriculture, philosophy, and the muses, abode there as long as he lived. Cardinal Fleury would fain have drawn him out of it, and sent him ambassador to Petersburg; but Desfouches would not stir: he chose rather to attend his lands and his woods, and to correct with his pen the manners of his own countrymen, than to go and converse with the Boyards of Russia. He died in 1754, leaving a daughter and a son: the latter, by order of Lewis XV. published at the Louvre an edition of his father's works, in 4 vols. quarto. Desfouches had not the gaiety of Regnard, nor the strong warm colouring of Moliere; but he is always polite, tender, and natural.

DETHMOLD, a town of Westphalia, on the river Wehara, 15 miles N. of Paderborn. Long. 8. 55. E. Lat. 52. 0. N.

DETROIT, a town of the United States, on the W. side of the strait, or river, that forms the communication between the lakes St. Clair and Erie. Long. 83. 2. W. Lat. 42. 22. N.

DEVA, a sea-port of Spain, in Guipuscoa, on the bay of Biscay, 15 miles S.E. of Bilbao. Long. 2. 40. W. Lat. 43. 24. N.

DEVENTO, a town of Bulgaria, with a Greek archbishop's see, seated on the Paniza, 65 miles N.E. of Adrianople. Long. 37. 33. E. Lat. 42. 33. N.

DEVETTO, or **ZAGORIA**, a town of Turkey in Europe, in Bulgaria, the see of a Greek archbishop; situate near the Black Sea, 58 miles N.E. of Adrianople, and 106 N.N.W. of Constantinople. Long. 27. 22. E. Lat. 42. 25. N.

DEVIZES, a borough in Wilts, with a market on Thursday, and a manufacture of ferges and other woollen stuffs. It sends two members to Parliament, and is seated on an eminence, 24 miles N.W. of Salisbury, and 89 W. of London. Long. 2. 2. W. Lat. 51. 20. N.

DEVON, a river of Perthshire, over which, in the beautiful vale of Glendevon, is a great curiosity, called the Rumbling Bridge. It is similar to that over the Braan, and consists of one arch, thrown over a horrible chasm, worn by the river, about eighty feet deep, and very narrow. In other places, the river has forced its way, in a surprising manner, through the rocks. At the Caldron-lin, it has worn away the softer parts of the stone, and formed immense pits, into which the water falls with a tremendous noise. Below this, the whole river is precipitated in one sheet, from a height of forty feet.

DEUX PONTS, a town of Germany, in the palatinate of the Rhine, capital of a duchy of the same name, seated on the Erbach, 49 miles N. by W. of Strasburg, and 50 S.W. of Mentz. Long. 7. 26. E. Lat. 49. 10. N.

DIACOUSTICS. See **ACOUSTICS** in this SUPPLEMENT.

DIANTHUS (*Encyel.*). Though carnations grow freely in almost any garden earth, and in it produce beautiful flowers, yet they are generally superior in that of a light loamy nature: and of this kind of soil the florists generally prepare a kind of compost in the following manner, especially for those fine varieties which they keep in pots. A quantity of loamy earth must be provided, of a light sandy temperature,

from an upland or dry pasture-field or common, taking the top spit turf and all, which must be laid in a heap for a year, and turned over frequently. It must then be mixed with about one third of rotten dung of old hot-beds, or rotten neat-dung, and a little sea-sand, forming the whole into a heap again, to lie three, four, or six months, at which time it will be excellent for use; and if one parcel or heap was mixed with one of these kinds of dungs, and another parcel with the other, it will make a change, and may be found very beneficial in promoting the size of the flowers. This compost, or any other made use of for the purpose, should not be sifted, but only well broken with the spade and hands. When great quantities of carnations are required, either to furnish large grounds, or for market, or when it is intended to raise new varieties, it is easily effected by sowing some seed annually in spring, in common earth, from which the plants will rise abundantly. Several good varieties may also be expected from the plants of each sowing; and possibly not one exactly like those from which the seed was sowed. The single flowers are always more numerous than the double ones; but it is from the latter only that we are to select our varieties. The season for sowing the seed, is any time from the 20th of March to the 15th of April. The plants generally come up in a month after sowing: they must be occasionally weeded and watered till July, when they will be fit for transplanting into the nursery beds. These beds must be made about three feet wide, in an open situation; and taking advantage of moist weather, prick the plants therein four inches asunder, and finish with a gentle watering, which repeat occasionally till the plants have taken good root. Here they must remain till September, when they will be so well advanced in growth as to require more room; and should then have their final transplantation into other three feet wide beds of good earth, in rows nine inches asunder, where they are to be placed in the order of quincunx. Here they are to remain all winter, until they flower, and have obtained an increase of the approved varieties of doubles by layers; and until this period, all the culture they require is, that if the winter should prove very severe, an occasional shelter of mats will be of advantage. In spring, the ground must be loosened with a hoe; they must be kept clear from weeds; and when the flower-stalks advance, they are to be tied up to sticks, especially all those that promise by their large flower-pods to be doubles.

The only certain method of propagating the double varieties is by layers. The proper parts for layers are those leafy shoots arising near the crown of the root, which, when about five, six, or eight inches long, are of a proper degree of growth for layers. The general season for this work is June, July, and the beginning of August, as then the shoots will be arrived at a proper growth for that operation; and the sooner it is done after the shoots are ready, the better, that they may have sufficient time to acquire strength before winter: those laid in June and July will be fit to take off in August and September, so will form fine plants in the month of October. The method of performing the work is as follows:—First provide a quantity of small hooked sticks for pegs. They must be three or four inches long, and their use is to peg the layers down to the ground. Get ready also in a barrow a quantity of light, rich mold, to raise the earth, if necessary, round each plant, and provide also a sharp penknife. The work is begun by stripping off all the leaves from the body of the shoots, and shortening those at top an inch or two evenly. Then choosing a strong joint on the middle of the shoot or thereabouts, and on the back or under side thereof, cut with the penknife the joint half-way through,

directing the knife upward so as to slit the joint up the middle, almost to the next joint above, by which you form a kind of tongue on the back of the shoot; observing that the swelling skinny part of the joint remaining at the bottom of the tongue must be trimmed off, that nothing may obstruct the issuing of the fibres; for the layers always form their roots at that part. This done, loosen the earth about the plant; and, if necessary, add some fresh mold, to raise it for the more ready reception of the layers; then with your finger make a hollow or drill in the earth to receive the layer; which, bend horizontally into the opening, raising the top upright, so as to keep the gash or slit part of the layer open; and, with one of the hooked sticks, peg down the body of the layer, to secure it in its proper place and position, still preserving the top erect, and the slit open, and draw the earth over it an inch or two, bringing it close about the erect part of the shoot; and when all the shoots of each plant are thus laid, give directly some water to settle the earth close, and the work is finished. In dry weather the waterings must be often repeated, and in five or six weeks the layers will have formed good roots. They must then be separated with a knife from the old plant, gently raised out of the earth with a point of a knife or trowel in order to preserve the fibrous roots of the layers as entire as possible; and when thus taken up, cut off the naked sticky part at bottom close to the root, and trim the tops of the leaves a little. They are then ready for planting either into beds or pots. In November the fine varieties in pots should be moved to a sunny, sheltered, situation for the winter; and if placed in a frame, to have occasional protection from hard frost, it will be of much advantage. In the latter end of February, or some time in March, the layers in the small pots, or such as are in beds, should be transplanted with balls into the large pots, where they are to remain for flower. To have as large flowers as possible, curious florists clear off all side-shoots from the flower-stem, suffering only the main or top buds to remain for flowering. When the flowers begin to open, attendance should be given to assist the fine varieties, to promote their regular expansion, particularly the largest kinds called *butchers*, whose flowers are sometimes three or four inches diameter. Unless these are assisted by art, they are apt to burst open on one side, in which case the flower will become very irregular: therefore, attending every day at that period, observe, as soon as the calix begins to break, to cut it a little open, at two other places in the indenting at top with narrow-pointed scissars, and hereby the more regular expansion of the petals will be promoted; observing, if one side of any flower comes out faster than another, to turn the pot about, that the other side of the flower may be next the sun, which will also greatly promote its regular expansion. When any fine flower is to be blown as large as possible, florists place spreading paper collars round the bottom of the flowers, on which they may spread their petals to the utmost expansion. These collars are made of stiff, white paper, cut circular, about three or four inches over, having a hole in the middle to receive the bottom of the flower, and one side cut open to admit it. This is to be placed round the bottom of the petals in the inside of the calix, the leaves of which are made to spread flat for its support: the petals must then be drawn out and spread upon the collar to their full width and extent; the longest ones undermost, and the next longest upon these; and so on; observing that the collar must nowhere appear wider than the flower; and thus a carnation may be rendered very large and handsome. These directions will answer equally well for the propagation of the pinks and sweet-williams, though neither of these require such nicety in their culture as the carnations.

DIBBLING (*Encycl.*). In the reports of the Society for bettering the Condition of the Poor, is the following extract from an account of the superior advantages of dibbling wheat, or setting it by hand, communicated by the Rev. Dr. Glafie.

"In the year 1759," "says the doctor," "I prevailed with Mr. Joseph Morland, one of the best farmers in my neighbourhood, to try, on a small scale, the experiment of setting wheat by hand, instead of sowing it. In this mode of agriculture, not more than one bushel an acre is required; whereas, in sowing, more than two bushels must be used. He tried his experiment upon an acre or two; and, the season being favourable, the produce was such as he had never before experienced. It was more than 40 bushels on an acre; being above a fourth beyond the average crop of that year. The straw was remarkably strong; and the wheat, the finest sample, and of the best quality, in the market. The persons employed in setting the wheat, were some women, of whose diligence and handiness in setting beans, he had the most experience. He found that five of these women would set an acre of wheat in a day. The soil he used was a strong loam, not without a mixture of gravel in some parts of it; and it was in good condition.—The next year he planted four or five acres with similar success; and he has since continued the practice, though on a small scale; his farm consisting of grass land, with a disproportionate quantity of arable. This year he has planted eight acres; and his example has now produced its effect on most of his neighbours; one of whom has, this year, set by hand 30 acres of wheat, and another as much as 40 acres.—Mr. Morland calculates his average produce from set wheat, for 10 years back (the last harvest excepted) to have been 32 bushels, or four quarters the acre; and that without any extra manure or dressing, beyond what a good practical farmer would generally apply; whereas in that country, where the rent of land is about 20s. per acre, no extraordinary manure being used in either case, the average produce of sown wheat does not exceed 24 bushels an acre. There is no other difference between the two modes of planting, except that, in the set wheat, the farmer may, if he chooses, keep his land perfectly clean, by using a small hoe; and may also earth up his wheat, if he wishes to do it; and that his straw is heavier and better, and of much more value, and the ears much longer, than of sown wheat. The account current between the two modes of planting 40 acres of wheat, stands thus; not to mention the increased value of straw, and the saving of expense in sowing.

Saving of seed on 40 acres, one bushel an acre,			
at 18s. per bushel	-	-	£.36 0 0
Deduct expence of setting ditto at 5s. per acre	-	-	10 0 0
			26 0 0
Add increased produce, being eight bushels			
per acre, at 18s. per bushel, on 40 acres	-	-	288 0 0
			£.314 0 0

"OBSERVATIONS.—Of setting wheat by hand the apparent, and ordinary, advantages are these:

"1st. The original saving of expence, and of seed; being upon 40 acres, at the present price of wheat, a clear advantage of 26l.—This is a considerable object, in time of scarcity; for, supposing the quantity of land cultivated with wheat in England, were not more than 800,000 acres, and half of it proper for this mode of cultivation; it would amount to 400,000 bushels of wheat; a circumstance of no small importance at any time, but particularly at the present.

"2d. The increase of the average produce of corn, being 320 bushels upon 40 acres. This increase of produce, reckoned

upon 400,000 acres, as before stated, would be 400,000 quarters of wheat, or 3,200,000 bushels.

"3d. The increased value of the straw; which stands more firm, and is less liable to be lodged. The straw is fairer and larger, and fetches a better price at the market, which is a great benefit in the neighbourhood of the metropolis, and of any large towns.

"4th. The very useful and acceptable employment it affords to the poor, particularly to women and children; and the advantage thereby given to cottagers with large families, and to the public in general, by the consequential saving in the poor rates.

"If it should be observed, that all kinds of land are not adapted to this mode of husbandry. The soil which Mr. Morland chose for his first experiment, was a strong loam, not without a mixture of gravel in some parts of it.—As to the expence of labour, five women will easily plant an acre in a day. For the setting, no line is necessary to be drawn; the women are directed to follow what is called the seam of the furrow; and they are desired to make the holes, at the distance of two inches, or rather more, in the row; and not to drop more than two seeds in each hole. The rows may be six or seven inches from each other, which will give the feed ample room to tiller.

"If this mode of cultivation were adopted in every kind of land, to which it is suited, it would save many hundred thousand bushels of seed a-year; it would make an increase of one-fourth upon such average crops, and give healthful and satisfactory occupation, and means of subsistence, to thousands of women and children, at the dead season of the year, when there is a general want of employment. It is at this period that most women and children consider themselves as laid up for the winter, and become a burthen upon the father of the family, and in many cases upon the parish. The wife is no longer able to contribute her share towards the weekly expences, unless (which is seldom the case) she has any peculiar skill in knitting, spinning, or sewing, or other merely domestic work.—In a kind of despondency she sits down, unable to contribute any thing to the general fund of the family, and conscious of rendering no other service to her husband, except that of the mere care of his family." As a gratifying example of a different kind, Dr. Glasse states the case of his principal labourer; who, in consequence of adopting this new mode of husbandry, earned, in October, 26 shillings a-week, by the labour of himself, his wife, and child; a benefit on his part, which has been attended by a saving to the doctor, on the eight acres so cultivated, of above eight bushels of wheat towards his winter supply; with a fair and reasonable prospect of an increased produce, to add to the general stock of the country, and to the restoration of plenty at the ensuing harvest.

Dibbling wheat was not attempted on a large scale, till an industrious farmer, in the vicinity of Norwich, had begun to dibble on less than an acre of land. The success of this experiment induced others to follow his example, and notwithstanding the ridicule they incurred for adopting so singular a practice, their crops were not only larger, but likewise so much superior to those of others, that dibbling has become the practice of every intelligent agriculturalist in Norfolk, whence it has spread into several other counties.

From a conclusive experiment made by the Rev. H. J. Clofe, of Trimley, near Ipswich, in the years 1783-4, it appears that drilling or dibbling greatly exceeds the broad-cast husbandry, on the best cultivated soils; and, besides the increased produce of grain, many other advantages arise from the former method.

Mr. Clofe employed the frame for setting wheat, represented in pl. 17.

This implement is two feet two inches wide, and provided with seven tines; but Mr. C. has since experienced that a frame of similar width, with five tines only, is preferable to one of seven.

The lands on which this method may be practised with the greater advantage, are either those after a clover-stubble, or where trefoil and grass-seed were sown in the spring before the last. These, after the usual manuring, are once turned over by the plough in an extended flag or turf, at ten inches wide, and the wheat is set in the manner already described. By this mode, three pecks of grain are sufficient for an acre; which, being immediately buried, is equally secured against the depredations of vermin, or the power of frost. The regular manner in which it rises, affords the best opportunity of keeping it clear from noxious plants, by weeding or hand-hoeing.

Dibbling is peculiarly beneficial when corn is dear; and, if the season be favourable, may be practised with great benefit, both to the public and the farmer: as it saves six pecks of seed-wheat per acre; and, if generally adopted, would of itself afford bread for more than half a million of people. It should, however, be observed, that in seasons when corn is sold at a low price, or the autumn unfavorable to the practice, it cannot be practised with advantage. Thus, in light lands, a very dry season prevents dibbling, because the holes will be filled up as soon as the instrument is withdrawn. In like manner, on strong and stiff clays, if it be very wet, the seeds in the holes cannot be properly covered by the bush-harrow.

DICTYS CRÉTENSIS (*Encyc.*). There are two anonymous writers still extant, who pretend to have written of the Trojan war previously to Homer; one of whom goes under the name of Dictys Crétensis, the other under that of Dares Phrygius. Before the history of Dictys are two prefaces; the first of which relates, that Dictys wrote six volumes of the Trojan war in Phœnician characters, and in his old age, after he was returned to his own country, ordered them, a little before his death, to be buried with him in a leaden chest, or repository, which was accordingly done; that, however, after many ages, and under the reign of Nero, an earthquake happened at Gnodius, a city of Crete, which uncovered Dictys's sepulchre, and exposed the chest; that the shepherds took it up, and expecting a treasure, opened it; and that, finding this history, they delivered it into the hands of somebody, who sent it to Nero, and he ordered it to be translated, or rather trans-charactered, from Phœnician into Greek. From which fine story nothing more has been concluded, than that this history was forged by some of Nero's flatterers, purely to curry favour with him: for he always affected a fondness for any thing relating to Trojan antiquities; and it is remarkable that, when Rome was in flames, he rejoiced as having seen the destruction of Troy. The other preface to Dictys is an epistle of L. Septimius, the Latin translator, in which he inscribes it to Arcadius Rufinus, who was consul in the reign of Constantine; and tells him much the same story of the history we have already related. As for Dares Phrygius, who is called by Homer, in the 5th book of the Iliad, a priest of Vulcan, he is said to have written a history of the destruction of Troy in Greek, which Ælian asserts to have been extant in his time, and which Photius also mentions in his Bibliotheca. The original is lost; but there is a Latin translation of it extant, which Cornelius Nepos is said to have made.

DIE, a town of France, in the department of Drome. It was lately an episcopal see, and is seated on the Drome, 24 mile S.W. of Valence. Long. 5. 23. E. Lat. 44. 42. N.

DIEBURG, a town of Germany, in the electorate of Mentz, 24 miles E.S.E. of Mentz.

DIEPHOLTZ, a town of Westphalia, capital of a county of the same name, subject to the electorate of Hanover. It is seated on the lake Dummer, 30 miles N.W. of Minden. Long. 8. 45. E. Lat. 52. 36. N.

DIERDORF, a town of Westphalia, with a castle, the residence of the counts; situate on the Wiedbach, eight miles N.N.E. of Coblenz.

DIERICH, a town of the duchy of Luxemburg, and the capital of a jurisdiction; situate on the Semois, 15 miles N.W. of Treves, and 15 N. of Luxemburg. Long. 5. 52. E. Lat. 50. 5. N.

DIERNSTEIN, a town of the archduchy of Austria. Near it is a castle, in which Richard I. king of England, was imprisoned. It is 38 miles W.N.W. of Vienna. Long. 15. 55. E. Lat. 48. 30. N.

DIESENHOFFEN, a considerable town of Switzerland, in Thurgau, seated on the Rhine, 5 miles S. of Schaffhausen. Long. 8. 42. E. Lat. 47. 35. N.

DIEST, a town of Austrian Brabant, on the river Demer, 15 miles N.E. of Louvain. Long. 59. E. Lat. 50. 59. N.

DIET (*Encycl.*). In Dr. Nisbet's Practical Treatise on Diet, we find some valuable remarks on the flesh of fowls and other animals commonly used as food. Some of these we shall select for the benefit of our valetudinary readers.

Fowls.—These afford a more wholesome and delicate diet than quadrupeds. It is easier also of digestion; but they afford at the same time a less proportion of real nourishment. Nor is their nourishment so general as that of quadrupeds, some parts of them being always tough and insipid, from their manner of life. Of birds, a greater number of the carnivorous kinds are eaten than of quadrupeds; but they are, however, chiefly those that live on fish, from which indeed they acquire a peculiar taste, but this is by no means so unpleasant as that of carnivorous quadrupeds. The time of using fowls requires more to be studied than that of quadrupeds, as they are frequently out of season, particularly in spring, when they pair; and where they are birds of passage, or migrate from one place to another, they require some residence, or to be in case, before they are fit for use.

Fowls as well as quadrupeds are much improved in size and fatness by domestication; but this is of two kinds: the first is making them familiar, and allowing them to feed as they please, which in the hen kind is known by what are called barn-door fowls—the other is properly cramming them, that is, shutting them up for the sole purpose of feeding. These arts of feeding no doubt give more succulence and tenderness to the food, and increase its alkalescency. From giving succulency they are an improvement; but from increasing alkalescency, they render the food more unfit for weak stomachs and convalescents, by whom this species of food is much used, though at the same time they render it more easy of solution. Exercise is necessary to give perfection to all food, for by this means the fat of the animal is equally dispersed through the muscular parts; while, when fatted hastily, it is accumulated in the cellular membrane. By the domestication, also, of fowls in general, their peculiar flavour, on which their excellence depends, is lessened; and by cramming them it becomes entirely lost. Hence also, unless their fibres are very tough, roasting is to be preferred to boiling them, on the same account.

Salmon.—The salmon is a very extensive article of food, and is used in three ways, either fresh, cured, or smoked. It is of a tender substance, sufficiently succulent and nourishing, but at the same time somewhat oily, and therefore heavy on the stomach. It differs in its richness and alkalescency according to the particular places in which it is taken. When middle-aged it is in most perfection, and it should neither be eaten too young nor too old.

Salmon trout differs chiefly in being soft and gelatinous.

Pike.—This is a fish of prey, and feeds on the smaller species. Hence it is termed the water wolf. Its flesh is short, compact, and close in its parts. The river pike is the best of this species, and considered as the least heating, though somewhat hard of digestion, and lying heavy on the stomach. It differs, however, much in different countries. It is also best in the winter season. This fish has been recorded as very long lived; a fact confirmed by the story of the one thrown into a pond by the emperor Frederick the Second, with a brass ring about its neck, which was caught two hundred and sixty-two years afterwards. The truth of this, however, may be called in question.

Carp.—The carp is a fish very long lived, and was first introduced into Britain in 1514. Like the pike, the river carp is the best. It often grows to an amazing size, and has been known to weigh two hundred pounds weight. It is best food in March, May, and June. It is not so dense as the pike, and therefore easier of digestion. The older it is, it becomes the firmer, better tasted, and more wholesome. From the spawn of this fish is made the caviare, a dish much used by the Jews. This fish can be made to live a considerable time out of water, and will even, by a particular mode of treatment, grow fat.

Perch.—The perch is a food superior to the two former, and is of two sorts, the river and sea perch. It is of a firm texture, but a tender substance, easily soluble, not glutinous, not heating, nor remarkably stimulant. When young its flavour is best, which it loses by age, and becomes rather ill-tasted. The best for use are the middle-aged. They should never be used in the months of March or April, which is the spawning time. They are best caught in clear water, for marshes and muddy places vitiate their flavour.

Whiting.—The whiting is a sea fish, tender, white, and delicate, with little gluten or viscosity, and therefore proper for the most weakly stomachs, conveying little stimulus to the system. The best sort are short, and they are much valued as an article of food.

Haddock.—Is a sea fish, and much resembles the whiting, but is firmer in its texture, and in general much larger in size. It is caught in high perfection in different parts on the coast of Britain, particularly in the month of January.

Cod.—The cod is also a sea fish, of a more dense and glutinous texture than the two former, and its delicate parts are the glutinous ones about the head and the fountains. It is used of three kinds—the fresh cod, the green or white cod, and the dried or cured cod—the difference lying in the preparation of the two last, the one being salted and barreled for use, the other being salted, and dried in the sun, or smoked. The green cod generally comes from Newfoundland; the dry cod, again, is taken on the coast of Placentia and Scotland. Both these kinds require to have their salt much extracted, by immersion in water, before being used. The pickle of cod is frequently used as an external application of a dissolving nature.

Eels.—These have no exercise, are fat and slimy; they contain much nourishment, but are difficultly perspirable; they are well tasted, but, from their viscosity, are apt to lie heavy on the stomach. They are dressed in a variety of ways, but are lightest when roasted, and should be well seasoned with condiment, particularly vinegar and horseradish, for when long retained on the stomach they become heating and oppressive. The best kind are taken in clear water. They are very retentive of life, and have been known to live five or six days out of water. From the skin a mucilage is made, reckoned of sovereign virtue, by the vulgar, in swellings.

Tench.—The tench is a fish of a delicate taste. It feeds generally in muddy places, and is said to be the only fish that

the pike spares. When it can be procured from clear water the flavour is always superior. It was much under-rated by the ancients, but in modern times it is esteemed equal to carp. Its name it derives from the peculiarity of its colour.

Trout.—Of this fish there are a great variety, but the salmon-trout is the best, being soft and gelatinous, and at the same time somewhat stimulant and alkaline. All trout, indeed, are a very putrescent food, and therefore easy of digestion. They should be eaten in their freshest state, and taken, if possible, from running water. They are best in summer, for then they are in best condition, and their flavour most delicate.

Corstorphine Cream.—Besides cheese, another form in which the curd is used in one part of Scotland, is in what is termed corstorphine cream. This is made by filling a vessel with skimmed milk, which has a hole in its bottom stopped with a peg; this vessel is placed within another filled with boiling water; and when this is done, it is allowed to remain in this situation for a day or two, according to the state of the weather; at the end of this period a coagulation of the milk has taken place, and the watery part of it subsided to the bottom. This watery part is then drawn off by opening the peg at the bottom of the vessel, and being again stopped up, the same operation is continued for twenty-four hours longer, when an additional water is again drawn off, and the consistence of the curd is thus rendered pretty thick; it is then agitated briskly with a wooden stick, and made fit for use. This form of curd is much used in the neighbourhood of Edinburgh; it forms an aliment tolerably nourishing, and in summer, from its proportion of acidity, is gratefully acid and cooling.

Rice.—This grain is the chief support of the greatest part of Asia, is the general vegetable aliment of the East, and has been even long employed in Europe for the same purpose. The peculiar qualities of this grain are not easily ascertained. It discovers little sweetness, and it is not much disposed either to aciescence or fermentation. But from its effects it is evident its nourishing parts must be in great proportion. Of all the grains it is certainly the most innocent, and the most useful in the case of invalids: it contains a thin, light and very soluble mucilage, which not being so disposed to acidity as the other mucilages of grain, is therefore less flatulent, and fits easy on the stomach. It has been supposed to possess something of an astringent quality, and has therefore been ordered as a common remedy in bowel complaints; but it shews no marks of an astringent quality when put to the test; and its good effects can, therefore, only arise from its demulcent nature, as blunting acrimony, and soothing irritation. The nutritious quality of rice has been supposed by some, attended with one noxious quality, viz. being hurtful to the eyes, on no rational or satisfactory foundation. The weakness of sight, and blindness of the Chinese, has been indeed ascribed to the frequent use of hot rice; but how this can operate, it is impossible to conceive, or in what manner it should differ, boiled, or in this different state, excepting in temperature and softness, which can only increase its solubility in the stomach. The source of impaired vision, therefore, is more to be sought for in the abuse of venery among that people, with their immoderate indulgence in tea, and in other narcotic and aromatic stimulants.

Rice is used in a variety of ways—in jelly, or decoction, which is made with it in the same way as with barley and oats, or other grain. Its chief consumption, however, is in puddings, and it is used as an ingredient in stews. Lately an attempt has been made, by mixing it with wheat, to form it into bread, in the proportion of three parts of wheat, to one of rice; and one peculiar quality it is said to possess, that its mixture corrects bad wheat flour. In this climate, rice is

generally very quickly digested, and the return of appetite takes place soon after its use. In the warmer climates, however, from the relaxed, debilitated state of the stomach of the inhabitants, it is found necessary, in order to prevent its lying long upon them, to conjoin it with a considerable quantity of strong spices. This grain is very much used in Carolina, and no bad consequence is found to follow it; a proof of the insufficient grounds on which its tendency to produce blindness is built.

On the whole, this grain, both for extent of produce, its proportion of nourishment, and its goodness, is preferable to all others; its flour being finer, and its texture more tender than any of them, which is particularly apparent by macerating the different grains in water, for of all of them the rice swells to the largest size; a proof of its parts are more intimately divided.

Potatoe.—As an intermediate substance between the farinaceous seeds and roots, we have placed here, though properly belonging to the roots, the potatoe.

The potatoe was first introduced into Europe in 1486, by Sir Francis Drake, and is originally a native of Peru; where, unless reared under a particular management, by little exposure to the sun, it possesses much of the quality of the nightshade, to which species it belongs. The potatoe is now a root of the first importance in Europe, as affording a mild wholesome nourishment; and next to the grains, it is most used of any vegetable production. The attention paid to its cultivation has produced a great many varieties of it; and they may be yet increased from the seed contained in the apples; but this variety differs only in the proportion each possesses of its constituent parts. The light, mealy potatoes are the best. The constituent parts of this root, when examined, consist: 1. of a dry powder, or starch, as in grains: 2. a fibrous matter, of a grey colour, similar to the roots of pot-herbs; and 3. a mucilage, resembling that of the esculent plants. By the process of boiling, these parts become intimately blended, have their solubility increased, and become easier digested. This root, in many countries, affords the chief proportion of their nourishment; a proof of its wholesomeness and alimentary quality, for both men and animals are known to get fat under its use; though, in proportion to bulk, it does not afford the same quantity of nourishment as the grains. From its possessing such a large proportion of watery parts, nearly one half, it cannot fail to be easily digested, and to pass in a very short time into chyle. Hence it is by no means of itself a permanent nourishment, and the appetite sooner returns after it than after most other kinds of diet. Flatulence and heartburn are also very seldom known to arise from it, though continued in very great quantities; and in many cases where vegetable diet comes to be prescribed, it has been the only substance found to agree. From its constituting an article in such general use, it has come to be prepared in a variety of forms. It is used in bread, its flour is employed in pastry, and it is also converted by the French into a sago and salad.

Though we have mentioned the potatoe as a root, it is not properly the root of the plant, but rather a sort of underground fruit, produced upon a confined branch. The real roots do not produce potatoes; they only serve the purpose of drawing nourishment from the soil, as the leaves above extract it from the atmosphere. The potatoe below, and the apple above, are in fact the same; but being in different elements, they assume different appearances. The one seems to be intended for the preservation of the species, the other for the food of animals. Such is the prolific nature of this vegetable, that from one large potatoe, 8 lb. of good sizeable ones have been produced. As an article of sustenance, the potatoe is greatly recommended by its palatable nature,

and by its being reared at little expence. Hence it is well suited as a provision for the poor. Potatoes are never unwholesome but from being reared in a bad soil, improperly preserved, or eaten to excess; circumstances which can all be easily guarded against. Given raw, they have been found highly useful in scorbutic complaints.

By some authors, potatoes have been considered as possessed of noxious qualities. But experience gives no sanction to this opinion; and had it been just, the truth of it must have been completely established long before this time in an article which forms so much the diet of the poor in every country, and especially in Ireland, where, on the contrary, the most healthy people are reared.

Mushrooms.—Where mushrooms prove deleterious, the first sensations they produce are qualmsiness, which soon increases to violent sickness: this is succeeded by giddiness, a palpitation of the heart, and flushing heat of the skin; with more or less redness of it. Swelling of the face also ensues, and sometimes a sensation all over the body, as if a general fulness or swelling prevailed. The patient fares in an unusual manner. All objects appear different from what they did before, a difficulty of breathing ensues, and the mind is strangely confused. Delirium and convulsions have been also known as frequent consequences of this attack. In other cases where the symptoms are mild, and do not appear for a good many hours after eating them, the sickness ends in cholera morbus, on the termination of which, the patient generally falls into a sound sleep, or a somewhat comatose state.

To relieve these symptoms as speedily as possible, the clearing the stomach of its noxious contents should be the first step; and the best emetic for this purpose is ten grains of the vitriolated zinc, which may even be repeated if the sickness does not abate. The emetic is then to be succeeded by the vegetable acids, which should be given in pretty considerable quantity, either in the form of vinegar or lemon-juice. These will be found an antidote against what remains of the poison.

Tea.—Tea is the dried leaves of a shrub, the produce of China and Japan. It is divided into two varieties, green and bohea, which vary somewhat in their particular flavour and taste, though they agree in the general qualities of being slightly astringent, bitterish, and aromatic. In their recent state they are possessed of a strong, narcotic property, which is carefully diminished by maceration and drying, so that the acrid juice in which it resides comes to be considerably dissipated. They are dried on iron plates, from a part of some tincture of which their astringent quality is derived; and so dangerous are they held by the Chinese, as not to be used for a twelvemonth after they are plucked. Thus only by a preparatory process are they rendered at all fit for the purpose of diet.

Tea was first imported into Britain about the year 1666, and was confined for some time to the tables of the people of fashion; but in consequence of the pleasantness of its flavour and its fascinating effects, it soon gained a preference over every other diluent beverage, and came into general use. Hence it has shared the fate of all articles in universal demand. Its qualities have been sophisticated, and it has received additions, altering its nature in some degree from what it was on its first importation. These additions consist, first in concealing a deficiency of natural flavour, or aromatic part, by the oils fragrant; secondly, from less attention being paid to the periods of gathering it; and thirdly, from care being employed in the time of curing it, or preparing it for use.

The general effects of no dietetic article are perhaps so little determined as those of tea. By one party it is described as a poison, by another it is extolled as a medicine of the first virtues. Truth, however, seldom lies in extremes; and in or-

der to form a just opinion of this important subject, we should examine, first, its effects in a state of concentration; secondly, in the form it is most used; and thirdly, trace the different situations of those who use it. With respect to the first, we find that, formed into an extract, or with its juice inspissated, it has been known to kill in the quantity of a few grains. The distilled water has been attended with the same fatal consequences, or, if not extinguishing life, it has produced incurable palsy. Even the effluvia of this herb, long snelt at, has been known to produce apoplexy; and several tea-brokers, who are accustomed to smell every box that is opened, have fallen victims to their profession in this way. These facts then sufficiently prove the powerful narcotic qualities of this plant, when employed in sufficient strength, or in a concentrated state. Experiments also made with it on small animals have produced the same fatal issue, and that in a very short space of time after the application of the infusion. The green tea seems also the most powerful, or possesses the greatest proportion of that active principle on which these effects depend. Indeed all the high-flavoured teas possess it in an eminent degree. In the common form of infusion in which tea is employed for dietetic use, none of these consequences arise. In the East it has been used in this form from time immemorial; but in England it did not become common till after the restoration, when it was introduced at court by Katherine of Portugal. From this time it has gradually come into general use, so much so, that the importation from China in 1777, was upwards of sixteen millions of pounds, and from that time to the present it has increased to no less than thirty millions. On its first use, it was generally prepared in decoction, or boiled in a kettle, either in milk or water, the Eastern method; but by this preparation its aromatic quality was considerably impaired. The infusion, therefore, in Europe, though different from the Eastern method, has been preferred; and by this infusion its narcotic quality is, perhaps, retained more strongly than when part is dissipated by boiling.

The excellence of this infusion will depend on three circumstances, the degree of heat of the water employed, the softness or quality of the water, and the time allotted for the infusion.

With respect to the first, the water should always be brought to the boiling point, and continued as nearly as possible in that degree of temperature; in regard to the second, the water should be mixed as little as possible with any adventitious particles of a saline or mineral nature; and with respect to the third, the vessel employed should be so large as to keep the infusion of an equal strength.

The effects of tea drunk in this way are to increase the digestive action of the stomach, and to augment the appetite. Hence it is particularly useful where the stomach is overloaded, and nourishment is taken to excess; but in the same way, where nourishment is deficient, or where the stomach is unable to receive it, like all other powerful stimulants, it must tend to injure the organ, and shew all the bad consequences of its narcotic quality, in exciting various morbid affections of the nervous system. It is in this way that its introduction into Europe has proved so pernicious to the lower ranks of society. Instead of an auxiliary to diet, as it ought to be, it has come to constitute the principal part of it, and is drunk at all times of the day, and in such a state of concentration as to act as a real poison upon the body. Indeed to this herb, more than to any other cause, we may attribute that change in the constitution of the inhabitants of this country, which has displayed itself so remarkably within this century. Formerly nervous complaints were little known or understood, now they are most frequently met with; nor can they be attributed to any other cause, as the introduction of no other dietetic article has

been in equal extent within such a short period of time. The highest degree of these complaints, pally, we find increased as four to one within the last thirty years. Hence the use of this article requires more caution, and attention to counteract its pernicious consequences, than any other with which we are acquainted. These consequences steal on by degrees: it affords a beverage fascinating to the taste; it excites a momentary hilarity of spirits after its use, and it is not till after some hours of enjoying of this exhilarating state that the faintness and sinking, correspondent to the previous excitement, ensue, which calls anew for the same repetition of it, or some other stimulant, to produce a similar effect. The drinking of tea, therefore, should only be conjoined with a due proportion of nourishment. Its narcotic effects should be corrected by boiling rather than infusion; and in some countries it is common to correct this effect by its junction with certain aromatic or sweet herbs. It is rendered grateful to the taste by the addition of milk and sugar, which should always bear a greater proportion in the making of it than they at present do.

Dr. Nisbet extends his remarks to various other articles of diet, with which it may be the interest of many to make themselves acquainted; for these, however, we refer to the doctor's treatise.

DIEU (LEWIS DE), minister of Leyden, and professor in the Walloon College of that city, was a man of great abilities, and uncommonly versed in the Oriental languages. He was born April 7, 1500, at Flushing, where his father, Daniel de Dieu, was minister. Daniel was a man of great merit, and a native of Brussels, where he had been a minister 22 years. He removed from thence in 1585, to serve the church at Flushing, after the Duke of Parma had taken Brussels. He understood Greek and the Oriental languages; and he could preach with the applause of his auditors in German, Italian, French, and English. The churches of the Netherlands sent him, in 1588, over to Queen Elizabeth, to inform her of the designs of the Duke of Parma, who secretly made her proposals of peace, though the King of Spain was equipping a formidable fleet against England.—Lewis studied under Daniel Colonius, his uncle by his mother's side, who was professor at Leyden in the Walloon College. He was two years minister of the French church at Flushing; and might have been court-minister at the Hague, if his natural aversion to the manners of a court had not refrained him from accepting that place. He thought the post which was offered him more proper for a man in years than a student. The prince commended his modesty and prudence. He was called to Leyden in 1619, to teach, with his uncle Colonius, in the Walloon College; and he discharged the duty of that employment with great diligence till his death, which happened in 1642. He refused the post of divinity-professor in the new university of Utrecht; and, if he had lived long enough, he would have had the same post in that of Leyden. He married the daughter of a counsellor of Flushing, by whom he had eleven children.

He published, in 1631, "A Commentary on the Four Gospels, and Notes on the Acts of the Apostles." His first care had been to examine the Latin versions of the "Syriac New Testament," made by Tremellius and Guido Fabricius Bodezianus; and that of St. Matthew's Gospel in Hebrew, made by Munster and Mercerus. He published also the "Revelation of St. John," which he printed both in Hebrew and Syriac characters, with a Latin version of his own. He published the "History of the Life of Jesus Christ," written in the Persian tongue by the Jesuit Jerom Xavier, with learned notes; and he joined to the original a Latin translation. "The History of St. Peter," written in the Persian language, was also published by him, with a Latin translation and notes. He drew up likewise "Rudiments of the Hebrew and Persian

Tongues, and a Parallel of the Grammar of the Oriental Tongues." Some things also of smaller note were published by his friends after his death.

DIEUZE, a town of France, in the department of Meurthe, remarkable for wells of salt water, which produce much salt. It is seated on the Scille, 22 miles N.E. of Nancy. Long. 6. 45. E. Lat. 48. 53. N.

DIEXALEDRIA, in natural history, a genus of pellucid and crystalliform spars, composed of two pyramids, joined base to base, without any intermediate column: the diexahedria are dodecahedral, or composed of two hexangular pyramids.

DIEZ, St. a town of France, in the department of the Vosges. It had lately a celebrated chapter, whose canons were obliged to produce proofs of nobility. It is seated on the Meurthe, 30 miles S.E. of Luneville. Long. 7. 4. E. Lat. 48. 20. N.

DIGBY (Sir EVERARD), an English gentleman, memorable for the share he had in the powder-plot, and his suffering on that account, was descended from an ancient family, and born some time in 1581. His father, Everard Digby, of Drytroke in Rutlandshire, esq. was a person of great worth and learning, had his education in St. John's College, Cambridge, where he took the degree of M.A. and published several treatises, some on learned, others on curious subjects: as, 1. *Theoria Analytica*, viam ad Monachium Scientiarum Demonstrans, 1579. 2. *De Duplici Methodo Libri duo*, Rami Methodum Refutantes, 1580. 3. *De Arte Natandi*, Libri duo, 1587. 4. A Dissuative from taking away the Goods and Livings of the Church. His son, of whom we are speaking, was educated with great care, but under the tuition of some Popish priests, who gave him those impressions which his father, if he had lived, might probably have prevented; but he died when his son was no more than eleven years of age. He was brought very early to the court of Queen Elizabeth, where he was much taken notice of, and received several marks of her majesty's favour. On the coming in of King James, he went likewise to pay his duty; as others of his religion did: was very graciously received; and had the honour of knighthood conferred upon him, being looked on as a man of fair fortune, pregnant abilities, and a court-like behaviour. He married Mary, daughter and sole heiress of William Mulhso, esq. of Gotherst in Buckinghamshire, with whom he had a great fortune, which, with his own estate, was settled upon the children of that marriage. He was drawn in to be privy to the gunpowder-plot; and though he was not a principal actor in this dreadful affair, or indeed an actor at all, yet he offered 1500l. towards defraying the expences of it; entertained Guy Fawkes, who was to have executed it, in his house; and was taken in open rebellion with other Papists after the plot was detected and had miscarried. Upon his commitment to the Tower, he persisted steadily in maintaining his own innocence as to the powder-plot, and refused to discover any who were concerned in it; but when he was brought to his trial at Westminster, Jan. 27, 1605-6, indicted for being acquainted with and concealing the powder-treason, taking the double oath of secrecy and constancy, and acting openly with other traitors in rebellion, he pleaded guilty. After this, he endeavoured to extenuate his offence; and then requested, that, as he had been alone in the crime, he might alone bear the punishment, without extending it to his family; and that his debts might be paid, and himself beheaded. When sentence of death was passed, he seemed to be very much affected; for, making a low bow to those on the bench, he said, "If I could hear any of your lordships say you forgave me, I should go more cheerfully to the gallows."

To this all the lords answered, " God forgive you, and we do." He was, with other conspirators, upon the 30th of the fame month, hanged, drawn, and quartered; at the west end of St. Paul's church in London; where he asked forgiveness of God, the king, the queen, the prince, and all the parliament; and protested, that, if he had known this act at first to have been so foul a treason, he would not have concealed it to have gained a world, requiring the people to witness, that he died penitent and sorrowful for it." Wood mentions a most extraordinary circumstance at his death, as a thing generally known; namely, that when the executioner plucked out his heart, and according to form held it up, saying, " Here is the heart of a traitor," Sir Everard made answer, " Thou lyest." But perhaps, as generally as it was known then, persons may be found in this incredulous age, that would hardly believe it, even if Wood himself had actually asserted it.

Sir Everard left at his death two young sons, afterwards Sir Kenelm and Sir John Digby; and expressed his affection towards them by a well-written and pathetic paper, which he desired might be communicated to them at a fit time, as the last advice of their father. While he was in the Tower, he wrote, in juice of lemon or otherwise, upon slips of paper, as opportunity offered; and got these conveyed to his lady by such as had permission to see him. These notes, or advertisements, were preserved by the family as precious relics; till, in 1675, they were found at the house of Charles Cornwallis, Esq. executor to Sir Kenelm Digby, by Sir Rice Rudd, bart. and William Wogan, of Gray's-Inn, esq. They were afterwards annexed to the proceedings against the traitors, and other pieces relating to the Popish plot, printed by the orders of Secretary Coventry, dated Dec. 12, 1678.

DIGBY (Lord George), an English nobleman of great parts, was son of John Digby earl of Bristol, and born at Madrid in Oct. 1612. In 1626 he was entered at Magdalen College in Oxford; where he lived in great familiarity with the well-known Peter Heylin, and gave manifest proofs of those great endowments, for which he was afterwards so distinguished. In 1636 he was created M.A. there, just after Charles I. had left Oxford; where he had been splendidly entertained by the university, and particularly at St. John's College, by Dr. Laud, afterwards Archbishop of Canterbury. In the beginning of the long parliament, he was disaffected to the court, and appointed one of the committee to prepare a charge against the Earl of Strafford, in 1640; but afterwards would not consent to the bill, " not only," as he said, " because he was unsatisfied in the matter of law, but for that he was more unsatisfied in the matter of fact." From that time he became a declared enemy to the parliament, and shewed his dislike of their proceedings in a warm speech against them, which he made at the passing of the bill of attainder against the said earl, in April 1641. This speech was condemned to be burnt, and himself, in June following, expelled the House of Commons. Jan. 1641-2, he went on a message from his majesty to Kingston upon Thames, to certain gentlemen there, with a coach and six horses. This they improved into a warlike appearance; and accordingly he was accused of high-treason in parliament, upon pretence of his levying war at Kingston upon Thames. Finding what umbrage he had given to the parliament, and how odious they had made him to the people, he obtained leave, and a licence from his majesty, to transport himself into Holland; whence he wrote several letters to his friends, and one to the queen, which was carried by a perfidious confidant to the parliament, and opened. In a secret expedition afterwards to the king, he was taken by one of the parliament's ships, and carried to Hull; but being in such a disguise that not his nearest relations could

have known him, he brought himself off very dexterously by his artful management of the governor Sir John Hotham. In 1643 he was made one of the secretaries of state to the king, and high-steward of the university of Oxford, in the room of William lord Say. In the latter end of 1645 he went into Ireland, and exposed himself to great hazards of his life, for the service of the king: from thence he passed over to Jersey, where the Prince of Wales was, and after that into France, in order to transact some important matters with the queen and Cardinal Mazarine. Upon the death of the king, he was exempted from pardon by the parliament, and obliged to live in exile, till the restoration of Charles II. when he was restored to all he had lost, and made knight of the Garter. He became very active in public affairs, spoke frequently in parliament, and distinguished himself by his enmity to Clarendon while Chancellor. He died at Chelsea, March 20, 1676, after succeeding his father as Earl of Bristol.

Many of his speeches and letters are still extant, to be found in our historical collections. There are also letters of his to his cousin Sir Kenelm Digby against Popery, mentioned in the preceding article; yet afterwards he became a Papist himself, which, with several other inconsistencies in his character, has been severely censured.

DIGBY (John), earl of Bristol, and father of the Lord George Digby, was by no means an inconsiderable man, though checked by the circumstances of his times from making so great a figure as his son. He was descended from an ancient family at Colehill in Warwickshire, and born in 1580. He was entered a commoner of Magdalen College, Oxford, in 1595; and the year following, distinguished himself as a poet by a copy of verses made upon the death of Sir Hen. Unton, of Wadley in Berks. Afterwards he travelled into France and Italy, and returned from thence perfectly accomplished: so that, soon falling under the notice of King James, he was admitted gentleman of the privy-chamber, and one of his majesty's carvers, in 1605. February following he received the honour of knighthood; and, in April 1611, was sent ambassador into Spain, as he was afterwards again in 1614. April 1616, he was admitted one of the king's privy-council, and vice-chamberlain of his majesty's household; and in 1618, was advanced to the dignity of a baron, by the title of Lord Digby, of Sherborne in Dorsetshire. In 1620 he was sent ambassador to the Archduke Albert, and the year following to Ferdinand the emperor; as also to the Duke of Bavaria. In 1622 he was sent ambassador-extraordinary to Spain, concerning the marriage between Prince Charles and Maria daughter of Philip III. and the same year was created Earl of Bristol. Being attacked, after his return to England, by that overbearing man the Duke of Buckingham, he repelled and worsted him; and thence greatly among the discontented in parliament. But the violence of that assembly soon disgusting him, he left them, and became a zealous adherer to the king and his cause; for which at length he suffered exile, and the loss of his estate. He died at Paris, Jan. 21, 1652-3.

He was the author of several works. Besides the verses above mentioned, he composed other poems; one of which, an air for three voices, was set by H. Lawes, and published in his *Airs and Dialogues*, at London, in 1653. 1. A Tract, wherein are set down those Motives and Ties of Religion, Oaths, Loyalty, and Gratitude, which obliged him to adhere unto the King in the late unhappy Wars in England. 2. A Tract, wherein he vindicateth his Honour and Innocency from having in any Kind deserved that injurious and mercilefs Censure, of being excepted from Pardon and Mercy either in Life or Fortunes. 3. An Appendix to the first tract. These two tracts which have the general title of his *Apology*, toge-

ther with the appendix, and two of his speeches in parliament, were printed at Caen, in 1647, and reprinted in 1656. The first speech was upon May 20, 1642, concerning an Accommodation of Peace and Union between the King and his two Houses of Parliament; and the second was upon June 11 following, in vindication of it. There are also extant other speeches of his; one particularly at the Council-Table at Oxford in 1642, in Favour of the Continuance of the War with the Parliament. It was spoken after Edge-Hill fight, and published at London the same year. He also published at Caen, in 1647, An Answer to the Declaration of the House of Commons, Feb. 11, 1648, against making any more Addresses to the King; and dedicated it to his good countrymen of England, and fellow-subjects of Scotland and Ireland. Several letters of this lord are to be found in the Cabala.

Besides these treatises in the political way, he was, in the earlier part of his life, the author of a work of a very different nature, namely, a translation of Peter du Moulin's book, entitled, A Defence of the Catholic Faith, contained in the Book of King James against the Answer of N. Coeffeteau, &c. 1610. He probably undertook this laborious and, as one should think, disagreeable task, at the request of that pedantic and theological monarch; at least, with a view of currying favour with him. The dedication, however, to the king is not in his own name, but in that of J. Sandford, his chaplain.

DIGGES (Leonard), an English gentleman famous for his mathematical learning, was descended from an ancient family, and born at Digges-Court in the parish of Barham in Kent; but we know not in what year. He was sent to University College in Oxford, where he laid a good foundation of learning; and retiring from thence without a degree, prosecuted his studies, and composed the following works: namely, 1. *Tectonicum*; briefly shewing the exact Measuring, and speedy Reckoning of all Manner of Lands, Squares, Timbers, Stones, Steeples, &c. 1556, 4to. Augmented and published again by his son Thomas Digges, 1592, 4to.; and reprinted there in 1647, 4to. 2. A geometrical practical Treatise, named *Pantometria*, in three books. This he left in MS. but, after his death, his son supplied such parts of it as were obscure and imperfect, and published it in 1591, folio; sub-joining, A Discourse geometrical of the five regular and platonical Bodies, containing sundry theoretical and practical Propositions, arising by mutual Conference of these Solids, Inscription, Circumscription, and Transformation. 3. *Prognostication everlasting of right good Effect*: or, Choice Rules to judge the Weather by the Sun, Moon, and Stars, &c. 1555, 1556, and 1564, 4to. corrected and augmented by his son, with divers general tables, and many compendious rules, 1592, 4to. He died about 1574.

DIGGES (Thomas), only son of Leonard Digges, after a liberal education, went and studied for some time at Oxford; and by the improvements he made there, and the instructions of his learned father, became one of the greatest mathematicians of his age. When Queen Elizabeth sent some forces to assist the oppressed inhabitants of the Netherlands, Digges was appointed muster-master-general of them; by which he had an opportunity of becoming skilled in military affairs. Besides the revising, correcting, and enlarging some pieces of his father's already mentioned, he wrote and published the following learned works himself: namely, 1. *Alae five Scalae Mathematicae*: or Mathematical Wings or Ladders, 1573, 4to. This book contains several demonstrations for finding the parallaxes of any comet, or other celestial body, with a correction of the errors in the use of the radius astronomicus. 2. An arithmetical-military Treatise, containing so much of Arithmetic as is necessary towards Military Discipline, 1579, 4to. 3. A geometrical Treatise,

named *Stratiticeae*, requisite for the Perfection of Soldiers, 1579, 4to. This was begun by his father, but finished by himself. They were both reprinted together in 1590, with several amendments and additions, under this title: An arithmetical warlike Treatise, named *Stratiticeae*, compendiously teaching the Science of Numbers, as well in Fractions as Integers, and so much of the Rules and Equations algebraical, and Art of Numbers collical, as are requisite for the Profession of a Souldier. Together with the Moderne militaire Discipline, Offices, Lawes, and Orders in every well-governed Campe and Armie, inviolably to be observed. At the end of this work there are two pieces; the first entitled A briefe and true Report of the Proceedings of the Earle of Leycester, for the Releife of the Towne of Sluce, from his Arrival at Vlissingh, about the End of June 1587, until the Surrender thereof 26 Julii next ensuing; whereby it shall plainlie appear, his Excellencie was not in anie Fault for the Loffe of that Towne: the second, A briefe Discourse what Orders were bett for repulping of foraine Forces, if at any Time they should invade us by sea in Kent, or elsewhere. 4. A perfect Description of the celestial Orbs, according to the most ancient Doctrine of the Pythagoreans, &c. This was placed at the end of his father's *Prognostication everlasting*, &c. printed in 1592, 4to. 5. A humble Motive for Affociation to maintain the Religion established, 1601, 8vo. To which is added, his Letter to the same Purpose to the Archbishops and Bishops of England. 6. *England's Defence*: or, a Treatise concerning Invasion. This is a tract of the same nature with that printed at the end of his *Stratiticeae*, and called, A briefe Discourse, &c. It was written in 1599, but not published till 1686. 7. A Letter printed before Dr. John Dee's *Parallatice Commentationis praxeosque nucleus quidam*, 1573, 4to. Besides these and his *Nova corpora*, he had by him several mathematical treatises ready for the press; which, by reason of lawsuits and other avocations, he was hindered from publishing. He died in 1595, but we know not at what age. He married, and had sons and daughters; of which more will be said in the next article.

DIGGES (Sir Dudley), eldest son of Thomas Digges, just mentioned, was born in 1583; and entered a gentleman-commoner of University College in Oxford, 1598. Having taken the degree of B.A. in 1601, he went and studied for some time at the inns of court; and then travelled beyond sea, having before received the honour of knighthood. After seeing and observing much, he returned home, and led a retired life, till 1618; when he was sent by James I. ambassador to the Czar, or Emperor of Russia. Two years after he was commissioned with Sir Maurice Abbot to go to Holland, in order to obtain the restitution of goods, taken by the Dutch from some Englishmen, in the East-Indies. He was a member of the third parliament of James I. which met at Westminster Jan. 30, 1620-1; and was so little compliant with the court measures, as to be ranked among those whom the king called ill-tempered spirits. He was likewise a member of the first parliament of Charles I. in 1626; and not only joined with those eminent patriots, who were for bringing Villiers duke of Buckingham to an account, but was indeed one of the chief managers in that affair, and so very active, that he was committed to the Tower, though soon released. He was again member of the third parliament of Charles I. in 1627-8, being one of the knights of the shire for Kent; but seemed to be more moderate in his opposition to the court, than he was in the two last, and voted for the dispatch of the subsidies. Nevertheless, when any attempts were made upon the liberties of his country, or the constitution of parliament, his spirits were roused, and he openly exerted them. In short, he was a

man of such consequence, that the court thought it worth their while to gain him over; and accordingly they tempted him with the advantageous and honourable office of master of the rolls, of which he had a reversionary grant Nov. 29, 1630, and became possessed of it April 20, 1636, upon the death of Sir Julius Caesar. But he did not enjoy it quite three years; for he died March 8, 1638-9, and his death was reckoned among the public calamities of those times.

He was a worthy good man, and, as a certain writer says, "a great alertor of his country's liberty in the world of times." He was the author of several performances in the literary way: 1. A Defence of Trade: in a Letter to Sir Thomas Smith, Knt. Governor of the East-India Company, 1615, 4to. After his death, there was printed under his name, 2. A Discourse concerning the Rights and Privileges of the Subject, in a Conference desired by the Lords, and had by a Committee of both Houses, April 3, 1628; 1642, 4to. 3. He made several speeches upon various occasions, inserted in Rushworth's Collections, and Ephemeris Parliamentaria. 4. He collected the letters that passed between the Lord Burleigh, Sir Francis Walsingham, and others, about the intended marriage of Queen Elizabeth with the Duke of Anjou, in 1570, and with the Duke of Alençon, in 1581. They were published in 1655, folio. The publisher, who signs himself A. H. says in the preface, that "this piece was never intended for the press, but had slept long amongst the papers of Sir Dudley Digges, a personage of known wisdom and integrity, and who understood well the value of this manuscript, which had nothing forged or supposititious in it.

Sir Dudley had a brother Thomas, and a son Dudley, who were both learned men and authors. His brother Thomas was educated in University College, Oxford, took the degree of B.A. in 1606, removed to London; and then, travelling beyond sea, studied in foreign universities: from whence returning a good scholar, and an accomplished person, he was created M.A. in 1626. He translated from Spanish into English, Gerardo, the Unfortunate Spaniard, 1622, 4to. written by Goncalo de Cespedes: and, from Latin into English verse, Claudian's Rape of Proserpine, 1617, 4to. He died in 1635, being accounted a good poet and orator; and a great master of the English, French, and Spanish languages.

His son Dudley, who was his third son, was also of University College, Oxford, where he took the degree of B.A. in 1631-2; and the year after was elected fellow of All-Souls College. He took a master's degree in 1635; and became a good poet and linguist, and a general scholar. He died in 1643; having distinguished himself only by the two following productions: 1. An Answer to a printed book entitled Observations upon some of his Majesty's late Answers and Expresses, Oxon, 1642. 2. The Unlawfulness of Subjects' taking up Arms against their Sovereign in what Case soever, with Answers to all Objections, Lond. 1643, 4to.

DROGES (West), was a celebrated comedian, formerly of the Haymarket, and for some time manager of the Edinburgh theatre. This gentleman is frequently spoken of in Mrs. Bellamy's Memoirs. He performed latterly in Dublin, and became useful to the Irish manager by giving him secret instructions; he was suddenly seized with a paralytic stroke, which rendered him incapable of following his profession, Necessity now obliged him to play the sycophant off the stage, and become entirely the manager's instrument: this procured him an allowance, but, at the same time, the envy and ill-will of all the company. His first appearance upon the stage was at Dublin in 1749. He died at Cork in 1786.

DIGITALIS (Enceyl). The following observations on the medical use and effects of the digitalis purpurea are ex-

tracted from an essay of Dr. Mease, resident physician at the port of Philadelphia.

The purple fox-glove, he says, is a medicine which, for some time, stood high in the list of the materia medica, but for various reasons appears to have, in some measure, lost the character once formed of it.—The causes influencing the success of the digitalis, may be referred to the following heads: 1. The season of the year in which the plant is collected will have a very considerable influence on the effects produced on the system. 2. The part of the plant employed ought likewise to be attended to, when forming a judgment of its virtues. 3. A frequent cause of the failure of the digitalis may be attributed to the careless mode of preparing it for use. 4. The adulteration of the plant with other vegetables. 5. The various modes of exhibiting this medicine; and 6. The particular condition of the patient at the time of its exhibition.

Dr. Mease very judiciously comments upon each of these particulars, and more at large upon the last. He examines with some acuteness the different opinions of physicians relative to this subject, and illustrates them with his own observation and experience on the effects of this powerful plant.—As a specimen of his method of reasoning, we shall quote the following remarkable passage:

"To account for the success of this remedy in dropsies, and diseases of too much action in the arterial system, is readily done. But, to reconcile the opposite testimony of Dr. Withering and others, with respect to their different success in dropsies of too little action, is very difficult: nay, to reconcile the contrary advice of Dr. Withering himself, who recommends the digitalis in mania and hemoptoe, 'with a bounding pulse,' and in dropsies with a weak one, is impossible. And here I may repeat a remark I formerly made, viz. 'That a medicine whose primary operation is the reduction of the force of the arterial system, when this is so intimately connected with the general strength of the body, should only succeed in those cases where the latter is considerably exhausted, appears not only to be paradoxical, but ill agrees with the uniformity observed in the operations of nature, in other parts of the animal economy.' It is incumbent on Dr. Withering to account for this apparent opposition in his own sentiments, and to satisfy the doubts of physicians, arising from the action of the remedy being directly contrary to the principles upon which alone certain dropsies can be cured. I may also remark, that it is much to be wished, physicians were more accurate in noting the state of their patient's system, at the time of prescribing this and other remedies; and also the state of the pulse at the same time, with its frequency; which, though so constantly stated, is of far less consequence in determining the situation of the system, as to the important point of the existence or absence of the inflammatory disposition, than the former. We should thus arrive with more certainty at the true virtues of a medicine, and be able to reconcile the contradictory accounts of physicians, respecting its utility in the same disease."

These golden remarks cannot be too often and too seriously repeated, particularly to the junior class of medical practitioners.—Our author quotes a striking passage from a letter of Dr. Withering to Dr. Woodville, published in the Medical Botany of the latter, in which the inattention of physicians, in the exhibition of digitalis, is severely censured, and he concludes with the following practical hints:

"It may not be improper to add some cautions and observations upon the use of digitalis, not mentioned in the above paper, for the information of those who may not have seen Dr. Withering's work, and may wish to exhibit the medicine.

"The doctor desires the medicine to be given in the doses in an infusion of the plant, which he prefers to every other form, and directs one drachm of the dried leaves to be infused for four hours in half a pint of boiling water, adding to the strained liquor half an ounce of any spirituous water, and an ounce of this infusion to be given twice a-day to an adult. If the patient be stronger than usual, or the symptoms very urgent, this dose may be given once in eight hours; and, on the contrary, in many instances, half an ounce at a time will be quite sufficient. (This method of exhibiting the medicine ought to be continued until it either acts on the kidneys or stomach, pulse or bowels: to be stopped upon the first appearance of any of these effects; the patient to drink freely during its operation.) But, without attending to this rule, I have known the digitalis prescribed in the various forms of decoction, pills made with soap, and in powder mixed with prepared chalk or magnesia; and though the two last substances may not act in any opposite way, yet they may divide the particles, and by clogging them, prevent application to the stomach, and thus diminish its activity. A tedious decoction will dissipate the virtue of many plants less volatile than digitalis; but a slight one will no doubt injure it, and ought therefore never to be employed. Pills are often made up with such substances, as render them soluble with difficulty. If we even suppose soap free from this objection, we nevertheless do not know what secret effects may be produced by it, on particular stomachs, to interrupt the action of the medicine; and certainly it will not be so readily applied to that organ, as in a watery form.

"In case of *ascites* and *anasarca*, when the patient is weak, and the evacuation of the water rapid, the use of a proper bandage is indispensably necessary. If the water should not be wholly evacuated, it is best to allow an interval of several days, before the medicine be repeated, in order that food and tonics may be exhibited.

"The flow of urine will often precede, sometimes accompany, and frequently follow the sickness at stomach, at the distance of some days, and not unfrequently be checked by the medicine, especially if given in too large doses. The sickness will sometimes cease, and recur again as violent as before, and will continue to recur for three or four days, at more distant intervals. These sufferings seldom occur, and are no objection to the use of digitalis, neither is the stone in the bladder."

Dr. Beddoes, who has written much on the properties of digitalis, says, "within three years I have seen many scores of phthical invalids from among the poorer classes. I have always had, close at hand, a number of opulent patients of the same description. Each class has, in fact, lain before me, almost as conveniently for comparison, as the objects of his attention lie before a scholar occupied in collating a set of manuscripts. In general, where I had all possible evidence of the existence of tubercles, the exhibition of digitalis has been perfectly successful. If I specify that it has succeeded in three such cases out of five, I believe I much underrate the proportion of favourable events. With regard to the poor, who apply for relief in sickness, there exists a perpetual cause of uncertainty. Their attendance slackens as their health improves; and they are apt to disappear upon complete recovery; nor is it always easy to find them out by enquiry. In the richer class I have found the proportion of fortunate cases more considerable than I have stated; and where digitalis alone fails, success is sometimes obtained by helps, of which I shall speak before quitting the subject.

"When ulceration has succeeded to interior disorganization, the greater difficulty of cure has appeared to me very

strongly marked. Why this should be, is easily comprehended from general analogy: its full illustration, by tracing the diversity of animal actions step by step, I relinquish to those who may think they understand the nature of phthical ulceration, and the effect of the particular situation which the ulcers occupy. Entire failure has appeared to me, on the one hand, most frequent in the neediest poor; and on the other, in those females of higher life, who, from transmitted feebleness, and the want of air and exercise, of wholesome hunger and digestion, appear more like the shadows of human beings, than substantial compounds of flesh, blood, and bone. And as one means for the conciliation of contradictory testimonies, respecting the effect of digitalis in confirmed or ulcerated consumption, I adhere to the opinion expressed in the West-country Contributions, 1799, pp. 534—5: viz. that robustness of constitution is peculiarly favourable to the action of digitalis in this disease."

Three cases of pulmonary affection are detailed, in which digitalis produced evident benefit. The case of Dr. Briggs is well worthy of notice; it is accurately drawn up by that physician himself, and the disease was evidently incipient tubercular phthisis.

On the mode of exhibition of digitalis Dr. Beddoes observes, "when the mild exhibition of digitalis produces no good effect, and the patient is not greatly reduced, I have occasionally found it useful to administer it in nauseating or in sickening doses. In a few cases the purulent expectoration has been lessened at every sickness, and under the use of intermediate small doses has failed to return to its former quantity.

"I have very frequently employed digitalis externally; but never alone. I am not, therefore, able to speak with confidence of the effects of this manner of using it. In cases where the common mode fails, I purpose to try friction vigorously, and hope sometimes to succeed. I imagine some analogy of operation between sickness from digitalis and sickness from failing. The persons, in whom I have seen consumption considerably mitigated, and the very few whom I have known perfectly cured, by a sea voyage, have not, any of them, belonged to the more puny division of the consumptive. And I apprehend delicate females, affected by this disease, rarely experience great relief from sea sickness. I do not, however, feel myself entitled to advance an opinion on this point. I merely offer a conjecture, principally wishing to excite the attention of observers."

And again, "when fox-glove is deficient in operation, I have found the conjunction of opium in large doses, of bitters and squills, powerful auxiliaries. I have often joined with it *hyocyamus* and *cicuta*."

The following observations are of considerable importance; "When digitalis has failed altogether in incipient consumption, I have occasionally found calomel succeed in a few instances." And, "I have sometimes given the *hydrargyrus cum creta*, and sometimes the simple mercurial pill, instead of calomel, without any variation in the effect. And I have of late often joined one or the other with digitalis.

"There is a state of confirmed consumption, in which, if an auxiliary to digitalis of given operation could be discovered, some lives would be saved. The state I allude to is of this nature. In some instances, when the fox-glove has removed the hectic fever, and greatly reduced the expectoration and cough, the decline shall become almost imperceptible; the patient frequently appearing chlorotic, but being really phthical, as the event most commonly, and sometimes dissection, has evinced. During this almost stationary period, the organs of sanguification appear inert; and the deficient production of blood (into which the chyle is probably converted in the lungs)

sufficiently accounts for that consumption of the body which denominates the disorder. This defect of sanguification explains the emaciating process, when there is no excess of action either in the capillaries or other parts of the vascular system, nor any apparent drain, or else less evacuation than exists in cases where there is no emaciation. Those principles which enter into new combination during muscular contraction, being derived from the blood, and blood not being formed in sufficient quantity, the substance of the body will be wasted by the mere vital movements. Neither will the fat be replaced as fast as it is absorbed; and of other parts. In phthisical children, where the attractions on which growth (or longitudinal extension of parts) depends, do not cease, though probably solids very different in constitution from the healthy solids are formed, it should seem that emaciation ought to go on with peculiar rapidity, if other circumstances were alike."

In his attempts to account for the "mode in which digitalis operates," the author seems to have adopted that theory which is known in this country by the name of *chemical physiology*. He says, "at present I can only enunciate an opinion, reserving full discussion to a future occasion. To whatever organ medicinal application is made, I consider the applied substance as a chemical compound. The organs themselves I consider likewise as chemical compounds, extremely variable, and of a peculiar nature for the time being. We know that certain changes in those organic compounds, which are first affected, will produce successive changes in connected parts, till perhaps the whole frame undergoes a change in its composition, and consequently in its actions. Some effects of these changes will be manifest; others more obscure; and others not ascertainable by any of our present methods of observation."

"There is nothing in all this peculiar to the beings which we usually denominate organized. Alterations in any body will produce alterations in a series of adjacent bodies to an indefinite extent. The changes produced by the burning of a candle may be traced far into the sublimary system; and by help of pretty close analogies, they may be pursued into a more remote region of the universe. In organized bodies, if secondary effects are more sudden or more sensible than in most others, this is owing to the close connection of their members, and to the easily variable constitution of each member. By virtue of their connection, the members of the galvanic piles, at present known, seem to influence one another as readily as the bodily organs; but being similarly constituted, there is presented no diversity but in the degree of operation."

Conceding to this opinion the merit of considerable ingenuity, we cannot, at the same time, allow it to contain an accurate generalization of the phenomena already known relating to organized nature.

The different branches of human knowledge can only be considered as connected expressions of facts following, in their arrangement, either the order of nature, or strict and obvious analogies; and, by the common consent of philosophers, they have been distinguished from each other by appropriate names. The phenomena relating to mechanics have been supposed to be distinct from the phenomena of chemistry; and as yet it would be considered as rash to class the galvanic facts as simple chemical changes: why then should we, in direct contradiction to the adopted modes of nomenclature, attempt to identify the powers producing living action, which are, with regard to us, unknown, with the agencies of organic matter, which are obvious and ascertained? It is surely better to confess our total ignorance of the laws of life, than to form obscure generalizations founded upon loose analogies concerning them; as in the one case we give full liberty to the in-

ventive powers of the human mind; but, in the other, we limit its exertions to a particular object, by holding up to view a theory which is most probably false, and concerning which it is nevertheless compelled to reason.

Indeed, after the first enunciation, Dr. Beddoes himself seems to have been fully aware of the danger and difficulty of systematizing concerning the organized nature. He says, "again, we can scarce be said to have advanced a step in vital chemistry. We are not acquainted with the constitution of any one organ in any one of its conditions. We know nothing of the difference between the several conditions compatible with life. How, therefore, the recipient and the received body modify each other in the first instance, remains a perfect mystery. Nor are we better informed as to many of the consequences of the primary modifications. Of some our senses may occasionally inform us; and would inform us of more, if they were more assiduously and advantageously applied. But we shall most grossly deceive ourselves, if we imagine that such observations as we at present take, can ever amount to a theory or systematical body of facts. They are, perhaps, almost remote effects, and therefore, relatively to us, uncertain—the more remote, the more uncertain; because, of the parts progressively affected, if any one, unknown to the observer, be in a different state at different times, or in different persons, the effect that has previously taken place, and is again expected, may fail to appear. Our judgment, however, respecting the character of medical agents must abide by effects, thus remote and uncertain."

The experiments made by Mr. King, on the comparative action of opium and digitalis on cold-blooded animals, which follow these preliminary observations, were well contrived, and their results are curious and worthy of attention. The account of them will not admit of abridgment; and we must content ourselves with giving Dr. Beddoes's generalization of facts concerning the mode of operation of digitalis, which, in some measure, is founded upon them.

"1. Digitalis, in a certain dose, will increase the action of the arterial system.

"2. It will increase the digestive power of the stomach, when that is impaired.

"3. It will often induce sleep, like opium.

"4. Like opium, in an over-dose it occasions languor and excessive sensibility, headach, dimness of vision, nausea, and bilious vomiting.

"5. It almost immediately produces great excitement in frogs, somewhat as opium does; and produces certain other effects, similar to those of opium."

DIGNAN, a town of Venetian Istria, three miles from the gulf of Venice. Long. 13. 5. E. Lat. 45. 10. N.

DIGNITY (*Encycl.*). To those who study human nature, there is a point which has always appeared intricate: how comes it that generosity and courage are more esteemed, and bestow more dignity, than good-nature, or even justice; though the latter contribute more than the former to private as well as to public happiness? This question, bluntly proposed, might puzzle even a philosopher; but, by means of the foregoing observations, will easily be solved. Human virtues, like other objects, obtain a rank in our estimation, not from their utility, which is a subject of reflection, but from the direct impression they make on us. Justice and good-nature are a sort of negative virtues, that scarce make any impression but when they are transgressed: courage and generosity, on the contrary, producing elevated emotions, enliven greatly the sense of a man's dignity, both in himself and in others; and for that reason, courage and generosity are in higher regard than the other virtues mentioned: we describe them as grand and elevated, as of greater dignity, and more praise-worthy.

This leads us to examine more directly emotions and passions with respect to the present subject : and it will not be difficult to form a scale of them, beginning with the meanest, and ascending gradually to those of the highest rank and dignity. Pleasure felt as at the organ of sense, named *corporeal pleasure*, is perceived to be low; and when indulged to excess, is perceived also to be mean: for that reason persons of any delicacy dissemble the pleasure they take in eating and drinking. The pleasures of the eye and ear, having no organic feeling, and being free from any sense of meanness, are indulged without any shame: they even rise to a certain degree of dignity when their objects are grand or elevated. The same is the case of the sympathetic passions; a virtuous person behaving with fortitude and dignity under cruel misfortunes, makes a capital figure; and the sympathizing spectator feels in himself the same dignity. Sympathetic distress at the same time never is mean: on the contrary, it is agreeable to the nature of a social being, and has general approbation. The rank that love possesses in the scale, depends in a great measure on its object: it possesses a low place when founded on external properties merely; and is mean when bestowed on a person of inferior rank without any extraordinary qualification: but when founded on the more elevated internal properties, it assumes a considerable degree of dignity. The same is the case of friendship. When gratitude is warm, it animates the mind; but it scarce rises to dignity. Joy bestows dignity when it proceeds from an elevated cause. If we can depend upon induction, dignity is not a property of any disagreeable passion: one is slight, another severe; one depresses the mind, another animates it; but there is no elevation, far less dignity, in any of them. Revenge, in particular, though it inflame and swell the mind, is not accompanied with dignity, not even with elevation: it is not however felt as mean or grovelling, unless when it takes indirect measures for gratification. Shame and remorse, though they sink the spirits, are not mean. Pride, a disagreeable passion, bestows no dignity in the eye of a spectator. Vanity always appears mean, and extremely so where founded, as commonly happens, on trivial qualifications.

We proceed to the pleasures of the understanding, which possess a high rank in point of dignity. Of this every one will be sensible, when he considers the important truths that have been laid open by science: such as general theorems, and the general laws that govern the material and moral worlds. The pleasures of the understanding are suited to a man as a rational and contemplative being, and they tend not a little to ennoble his nature; even to the Deity he stretcheth his contemplations, which, in the discovery of infinite power, wisdom, and benevolence, afford delight of the most exalted kind. Hence it appears, that the fine arts, studied as a rational science, afford entertainment of great dignity; superior far to what they afford as a subject of taste merely.

But contemplation, however in itself valuable, is chiefly respected as subservient to action; for man is intended to be more an active than a contemplative being. He accordingly shews more dignity in action than in contemplation: generosity, magnanimity, heroism, raise his character to the highest pitch: these best express the dignity of his nature, and advance him nearer to divinity, than any other of his attributes.

Having endeavoured to assign the efficient cause of dignity and meanness, by unfolding the principle on which they are founded, we proceed to explain the final cause of the dignity or meanness bestowed upon the several particulars above mentioned, beginning with corporeal pleasures. These, as far as useful, are, like justice, fenced with sufficient sanctions to pre-

vent their being neglected: hunger and thirst are painful sensations; and we are incited to animal love by a vigorous propensity: were corporeal pleasures dignified over and above with a place in a high class, they would infallibly overturn the balance of the mind, by outweighing the social affections. This is a satisfactory final cause for refusing to these pleasures any degree of dignity: and the final cause is not less evident of their meanness, when they are indulged to excess. The more refined pleasures of external sense, conveyed by the eye and the ear from natural objects and from the fine arts, deserve a high place in our esteem, because of their singular and extensive utility: in some cases they rise to a considerable dignity; and the very lowest pleasures of the kind are never esteemed mean or grovelling. The pleasure arising from wit, humour, ridicule, or from what is simply ludicrous, is useful by relaxing the mind after the fatigue of more manly occupation: but the mind, when it surrenders itself to pleasure of that kind, loses its vigour, and sinks gradually into sloth. The place this pleasure occupies in point of dignity, is adjusted to these views: to make it useful as a relaxation, it is not branded with meanness; to prevent its usurpation, it is removed from that place but a single degree: no man values himself for that pleasure, even during gratification; and if it have engrossed more of his time than is requisite for relaxation, he looks back with some degree of shame.

In point of dignity, the social emotions rise above the selfish, and much above those of the eye and ear: man is by his nature a social being; and to qualify him for society, it is wisely contrived, that he should value himself more for being social than selfish.

The excellency of man is chiefly discernible in the great improvements he is susceptible of in society: these, by perseverance, may be carried on progressively, above any assignable limits; and even abstracting from revelation, there is great probability, that the progress begun here will be completed in some future state. Now, as all valuable improvements proceed from the exercise of our rational faculties, the author of our nature, in order to excite us to a due sense of these faculties, hath assigned a high rank to the pleasures of the understanding: their utility, with respect to this life as well as a future, entitles them to that rank.

But as action is the aim of all our improvements, virtuous actions justly possess the highest of all the ranks. These, we find, are by nature distributed into different classes, and the first in point of dignity assigned to actions that appear not the first in point of use: generosity, for example, in the sense of mankind is more respected than justice, though the latter is undoubtedly more essential to society; and magnanimity, heroism, undaunted courage, rise still higher in our esteem: the reason of which is explained above.

DILIGENCE, in Scots law, signifies either that care and attention which parties are bound to give, in implementing certain contracts or trusts, and which varies according to the nature of the contract. Or it signifies certain forms of law, whereby the creditor endeavours to operate his payment, either by affecting the person or estate of the debtor.

DILLA, MOUNT, a remarkable promontory of the coast of Malabar, 20 miles N. by W. of Tillicherry. Long. 75. 2. E. Lat. 12. 1. N.

DIMOTUC, a town of Romania, with a Greek archbishop's see; seated on a mountain, surrounded by the Meriza, 12 miles S.W. of Adrianople. Long. 26. 15. E. Lat. 41. 35. N.

DINANT, a town of France, in the department of the North Coast, seated on a craggy mountain, at the foot of which is the river Rance, 20 miles S. of St. Malo. Long. 1. 58. W. Lat. 48. 20. N.

DINANT, a town of Germany, in the bishopric of Liege, with a castle, seated near the Meuse, 12 miles S. of Namur. Long. 4. 51. E. Lat. 50. 17. N.

DINASMONDY, a town in Merionethshire, with a market on Friday, 18 miles S. of Bala, and 196 N.W. of London. Long. 3. 40. W. Lat. 52. 37. N.

DINCHURCH, a village in Kent, in Romney Marsh, three miles N.E. of Romney. Here are kept the records of the Marsh; and the court is held by the lords of the Marsh, and the members of the corporation, who are appointed by statute, 33 Edward III. to regulate all affairs concerning the Marsh.

DINKELSPIL, a free imperial town of Suabia. It has a great and a little council: the former is a mixture of Papists and Lutherans; but the little one are all Papists. It carries on a trade in cloth and reaping-hooks, and is seated on the Wernitz, 37 miles S.W. of Nuremberg. Long. 10. 20. E. Lat. 49. 0. N.

DINGELFING, a town of Lower Bavaria, seated on the Isar, 20 miles N.E. of Landschut. Long. 12. 36. E. Lat. 48. 40. N.

DINGLE, a sea-port of Ireland, in the county of Derry, seated in Dingle Bay, four miles W. of Limerick. Long. 8. 40. W. Lat. 53. 42. N.

DIO CASSIUS, a famous Greek historian, a native of Nicæa, a city of Phrygia, was governor of Pergamus and Smyrna, and commanded in Africa and Pannonia. In the year 229, he was raised by Alexander Severus to the dignity of consul; but not being agreeable to the troops, was obliged to retire to the place of his birth, where he ended his days. He composed a Roman History in Greek, a part of which only has been handed down to us. He is accused of partiality against Pompey, Cicero, Seneca, and several other great men. He is chiefly esteemed for the speeches he puts into the mouths of Agrippa and Mæcenæ, when Augustus advised with them whether he should preserve the empire, or restore the ancient government.

DIOCLESIAN. The bloody persecutions of the Christians, in the time of this emperor, forms a chronological æra, called the *era of Dioclesian*, or of the martyrs. The causes of a supposed extinction of Christianity at that period, having been the subject of some literary controversy, the following remarks on the subject, which appeared in the British Magazine for 1800, may not be unacceptable to many of our readers.

Let it be supposed, says the writer, that the Christian religion, instead of obtaining a decisive and lasting victory over Paganism, in the reign of Constantine the Great, was itself totally annihilated by the persecution, commonly called the Dioclesian. In order to a more complete inversion of the fact, let it be further supposed, that the progress of this religion, immediately upon its first promulgation, was exceedingly rapid, and that it gradually declined under successive persecutions, till it became extinct under that which has been mentioned. This period is fixed upon for the final overthrow of Christianity, because it supplies the most adequate cause of the supposed event, which comes nearest in point of time to the opposite of the real one.

The patrons and adherents of the triumphant religion would, without doubt, ascribe the destruction of an enemy, once so formidable, to the miraculous interposition of the dei-

ties whom they worshipped. Not to interfere with this opinion, it may yet be allowed to the philosopher, whose province it is to trace or supply the latent and intricate connection between causes and effects, to confine his consideration to those *natural and secondary causes*, which may be supposed to have at least contributed to the production of the extraordinary and important event. And it does not appear that any causes of that description can be assigned with greater probability than the *five following*; 1. the inflexible, and, if we may use the expression, intolerant zeal of the Christians; 2. the doctrine of a future life; 3. the miraculous powers ascribed to the primitive church; 4. the pure and austere morals of the Christians; 5. the union and discipline of the Christian republic.

I. No qualities could be imagined more directly calculated to frustrate the attempts of the primitive-Christians than the inflexibility, and, if we may use the expression, the intolerance, of their zeal. Their system of protelytism was fundamentally erroneous. The religion which they proposed was indeed too far of a general nature, that none were excluded from the benefit of it: it was intended for a common blessing. Yet, with all this liberality, Christianity was, in the strictest sense, and to the last degree, an unfocial religion. It would neither accommodate itself to the reigning superstitions, nor would it admit any association with them. It was determined to stand alone; and wherever it prevailed, it must prevail upon the ruins of all other systems. With such pretensions, the heralds of the Gospel could not reasonably hope for a favourable reception. Their apparent arrogance could only serve to provoke the indignation of those whom they endeavoured to convert; and the zeal with which they prosecuted their cause, especially if it were so extravagant as has with great confidence been asserted, would, according to the *natural course of things*, have a direct tendency to defeat their object*.

II. The doctrine of a future state of retribution, of reward to the good, and of punishment to the wicked, was by no means a peculiar doctrine of Christianity. Heathenism had its Elysium and its Tartarus. The natural apprehension, however, with respect to a future state, had produced in the majority of the civilized Gentiles, the common people as well as the higher ranks of the philosophers, a disbelief and contempt of the doctrine;—at least, of that part which relates to future punishment†. Socrates, Cicero, and Seneca, admitted only the alternative of the mortality of the soul, or of its future enjoyment or happiness‡. Christianity came forward to revive the exploded doctrine: it arrayed the happiness of the righteous with new glories, and conferred new terrors upon the place of punishment. But the heathens had given up their Elysium, and the spiritual heaven of the Christians was not more alluring: they had succeeded in dissipating the dread of their Tartarus, and it was not to be expected that they should tamely submit to the fresh imposition of the doctrine, rendered more formidable both by the evidence which supported it, and by the additional horrors with which it was attended.

III. A claim to miraculous powers, when considered as a natural cause, must be understood of those which are unjustly pretended to; or, which are false: for real miracles are a supernatural cause, and are only compatible with a true religion. Miracles, thus explained, were nothing new to the heathens. Their own religion was founded upon them. Neither were

* For the indignation of the heathens against the Jews on account of the infidelity of their religion, see Josephus cont. Apion, lib. 2. §. 7. For the same fact, more especially with respect to the Christians, see Warburton's Divine Legation, book 2. § 6.

† This is proved with triumphant evidence by Leland, in his Advantage and Necessity, &c, book 3. ch. 8.

‡ Apologia Socratis, § 22. Cicero de Senectute, sub finem. Seneca, Ep. 24.

they averse to admit the claims of Christianity. But then they expected, they thought themselves entitled to, a return of the compliment. When, therefore, they found that the religion proposed to their acceptance, instead of being flattered, or even contented with this honour, aspired to sovereign and exclusive dominion; its arrogant pretensions would naturally excite the indignation of the votaries of heathenism. And the less able they were to ascribe to imposture the miracles to which it pretended, the more violent would be their prejudices, and the more extravagant their resentment.

IV. While the religion of the Christians was calculated to make them benefactors to the world, by engaging them in the practice of the whole circle of duty, to God, their neighbour, and themselves, they nevertheless considered that part of it which concerns the supreme Being as paramount to all the rest, and in every case of competition entitled to the preference. From this principle flowed their purity, and what is denominated their austeriety. It was a principle which they held in common with Socrates*. But, however reasonable, it could never fail to give offence; and it has always been observed, that a conspicuous moral superiority, on account of the reproach which it conveys to the generality, is almost sure to create enemies†. Nor is there any hatred so virulent as that which has an unjust foundation‡. Even the fortitude which the Christians displayed in their martyrdom, could not escape a sinister interpretation. It was branded as obstinacy§. And then, instead of conciliating the compassion, or exciting the admiration of the heathens, it only served for a more specious pretence of prosecuting the persecution of these unhappy sufferers with increased severity. Such were the fruits of the virtues of the primitive Christians.

V. The Romans, who valued themselves principally upon their knowledge of the art of government, would behold with extreme jealousy the rise and establishment of an independent and increasing society within the bosom of their own dominions—an *imperium in imperio*||. Nor would the assumption of the character of religion in any way abate this jealousy; of which their treatment of the Bacchic mysteries at Rome is a remarkable instance¶. When, therefore, the converts to Christianity had, in the time of Nero, according to Tacitus**, become a vast multitude, and, in the exulting language of Tertullian, had filled every part of the empire††, it was not to be expected that the rulers of that empire would behold with indifference a society, however peaceable the spirit of its institution, and the conduct of its members, which their principles or their prejudices could only dispose them to look upon as a conspiracy. It was the fact. And the causes which have been mentioned, uniting their influence with this, produced that series of progressive persecutions, which had for their object not only the subjugation, but the extermination and destruction of Christianity.

When Christianity had thus armed against itself, the power and policy of a mighty empire, the jealousy of its magistracy, both supreme and subordinate, the interests of its priesthood,

the virulent and well-disciplined rancour of its philosophers, and the furious passions of a superstitious and inflamed populace, it were justly to be esteemed a miracle, if a religion, of which non-resistance was the most specious reproach, should escape the destruction with which it was threatened.

Such are the natural causes by which the event here supposed may be accounted for. Nor will the objection, that precisely the same causes have been assigned for a fact directly the opposite‡‡, have any weight with the philosopher, who is satisfied that the *flexibility* of an argument, as it enlarges the sphere of its operation, and gives it liberty to act in any direction, is rather a recommendation than a disparagement to it. And it can with as little reason be expected, that he who is so justly offended at the *obstinate inflexibility* of the Christian, will so far lose sight of the consistency of his character, as to regard it with greater indulgence, even though *truth herself* should venture to assume it.

DIONYSIUS (Areopagita), was born at Athens, and educated there. He went afterwards to Heliopolis in Egypt; where, if we may believe some writers of his life, he saw that wonderful eclipse which happened at our Saviour's passion, and was urged by some extraordinary impulse to cry out, *Aut Deus patitur, aut cum patiente dolet*; "Either God himself suffers, or condescends with him who does." At his return to Athens he was elected into the court of Areopagus, from whence he derived his name of *Areopagite*. About the year 50 he embraced Christianity; and, as some say, was appointed first bishop of Athens by St. Paul. Of his conversion we have an account in the 17th chapter of the Acts of the Apostles.—He is supposed to have suffered martyrdom; but whether under Domitian, Trajan, or Adrian, is not certain. We have nothing remaining under his name, but what there is the greatest reason to believe spurious.

DIONYSIUS (Bishop of Corinth), flourished under the reigns of Marcus Antoninus and Commodus, and is supposed to have suffered martyrdom about the year 178. We know little more of him than what appears from some of his epistles, preserved by Eusebius: from which we learn, that he was not only very diligent in his pastoral care over the flock committed to him, but that he extended his care likewise to the inhabitants of all other countries and cities. He wrote a letter to the Lacedæmonians, in which he exhorts them to peace and concord: another to the Athenians, in which he recommends purity of faith and evangelical holiness: a third to the Nicomedians, to bid them beware of the heresy of Marcion: a fourth to the churches of Crete: a fifth to the churches of Pontus: a sixth to the Gossians, in which he admonishes Pinytus, their bishop, not to impose too severely upon the brethren the heavy burthen of continence, but to consider the frailties and infirmities of the flesh. He wrote also a seventh letter to the Romans, in which he mentions the famous epistle of Clements to the Corinthians; which, as we learn from him,

* Plat. Ap. Sac. § 11.

† Virtutem incolumen odimus. Horat. Od. lib. 3. 24. Etiam gloria ac virtus inensus habet, ut nimis ex propinquo diversa arguens. Tacitus Annal. lib. 4. § 33.

‡ Odium, quorum causæ aciores, quia iniquæ. Tac. Ann. lib. 1. § 33.

§ With Pliny it was "inflexibilis obstinatio," lib. 10. ep. 97; with Marcus Antoninus *φίλη παρρησία*, lib. 10. § 3. In another cause it might have suggested the—*Justum et tenacem propositi virum*, &c.

|| Tu regere imperio populos, Romane, memento, hæc tibi erunt artes, &c. Virg. En. lib. 6. 851. &c.

¶ Liv. Hist. lib. 39. § 8, particularly § 16.

‡‡ Gibbon's Decline and Fall, &c. ch. 15.

was wont, at that time, to be publicly read in their churches. But none of these letters are now extant.

DIONYSIUS (Bishop of Alexandria), was born a Heathen, and of an ancient and illustrious family. He was a diligent enquirer after truth, which he looked for in vain among the sects of philosophers; but at last found it in Christianity, in which he was probably confirmed by his preceptor Origen. He was made a presbyter of the church of Alexandria in 232; and, in 247, was raised to that see upon the death of Heracles. When the Decian persecution arose, he was seized by the soldiers and sent to Taposiris, a little town between Alexandria and Canopus; but he escaped without being hurt, of which there is a marvellous account in the fragments of one of his letters, which Eusebius has preserved. He did not come off so well under the Valerian persecution, which began in 257: for then he was forcibly hurried off in the midst of a dangerous illness, and banished to Cephros, a most desert and uncultivated region of Lybia, in which terrible situation he remained for three years. Afterwards, when Gallienus published an edict of toleration to the Christians, he returned to Alexandria, and applied himself diligently to the offices of his function, as well by converting heathens, as by suppressing heretics. The Novatian heresy he laboured to put a stop to; he endeavoured to quiet the dispute, which was risen to some height, between Stephen and Cyprian, concerning the re-baptization of heretics: but he attempted both these things with Christian moderation and candour. For it must be acknowledged to his credit, that he seems to have possessed more of that spirit of gentleness and meekness, than was usually to be found in those primitive and zealous times. A little before his death he was called to a synod at Antioch, to defend the divinity of Jesus Christ against Paul of Samosata, who was bishop of Antioch: but he could not appear by reason of his great age and infirmities. He wrote a letter however to that church, in which he explained his own opinion of the matter, and refuted Paul: whom he thought to very blameable for advancing such an error, that he did not deign to salute him even by name. He died in the year 267; and, though his writings were very numerous, yet scarce any of them are come down to us, except some fragments preserved by Eusebius.

DIOPHANTUS, a celebrated mathematician of Alexandria, reputed to have been the inventor of algebra. When he lived, is not known: some have placed him before Christ, and some after, with equal uncertainty. He wrote 13 books of arithmetic; which the astronomer Regiomontanus tells us, are still preserved in MSS. in the Vatican library: Meziriac's edition of seven of these books has been several times reprinted, with notes and illustrations.

DIPLOMATICS (*Encycl.*). In order to understand the nature of diplomas, and manuscripts, and to distinguish the authentic from the counterfeit, it is necessary to know that the paper of the ancients came from Egypt, and was formed of thin leaves or membranes, taken from the branches of a tree named *Papyrus*, or *Bibulum Ægyptiacum*, and which were pasted one over the other with the slime of the Nile, and were pressed and polished with a pumice-stone. This paper was very scarce; and it was of various qualities, forms, and prices, which they distinguished by the names of *charta hieratica*, *lurica*, *augusta*, *amphitheatica*, *fastica*, *tanirica*, *emporetica*, &c. They cut this paper into square leaves, which they pasted one to the other, in order to make rolls of them: from whence an entire book was called *volumen*, from *volvendo*; and the leaves of which it consisted, *pagine*. Sometimes, also, they pasted the leaves all together by one of their extremities, as is now practised in binding; by this method they formed the

back of a book, and these the learned call *cordices*. They rolled the volume round a stick, which they named *umbilicus*; and the two ends that came out beyond the paper, *cornua*. The title, wrote on parchment, in purple characters, was joined to the last sheet, and served it as a cover. They made use of all sorts of strings or ribbands, and even sometimes of locks, to close the book; and sometimes also it was put into a case. But there is not now to be found, in any library or cabinet whatever, any one of these volumes. We have been assured, however, by a traveller, that he had seen several of them in the ruins of Herculaneum; but so damaged, the paper so stiff and brittle, by the length of time, that it was impossible to unroll them, and consequently to make any use of them; for on the first touch they fell into shatters. We shall speak hereafter of those books they call *codices*.

We are ignorant of the precise time when our modern paper was invented; and when they began to make use of pens in writing, instead of the stalks of reeds. The ink that the ancients used, was not made of vitriol and galls, like the modern, but of foot. Sometimes also they wrote with red ink made of vermilion; or in letters of gold, on purple or violet parchment. It is not difficult for those who apply themselves to this study, to distinguish the parchment of the ancients from that of the moderns, as well as their ink and various exterior characters: but that which best distinguishes the original from the counterfeit, is the writing or character itself; which is so distinctly different from one century to another, that we may tell with certainty, within about 40 or 50 years, when any diploma was written. There are two works which furnish the clearest lights on this matter, and which may serve as sure guides in the judgments we may have occasion to make on what are called ancient diplomas. The one is the celebrated treatise on the Diplomatic, by F. Mabillon; and the other, the first volume of the *Chronicon Gotvicense*. We there find specimens of all the characters, the flourishes, and different methods of writing, of every age. For these matters, therefore, we must refer our readers to those authors; and shall here only add, that

All the diplomas are wrote in Latin, and consequently the letters and characters have a resemblance to each other: but there are certain strokes of the pen which distinguish not only the ages, but also the different nations; as the writings of the Lombards, French, Saxons, &c. The letters in the diplomas are also usually longer, and not so strong as those of manuscripts. There has been also introduced a kind of court-hand, of a very disproportionate length, and the letters of which are called *Ætules litteræ*, *crispæ ac protrahitiores*. The first line of the diploma, the signature of the sovereign, that of the chancellor, notary, &c. are usually wrote in this character.

The signature of a diploma consists either of the sign of the cross, or of a monogram or cipher, composed of the letters of the names of those who subscribed it. The initial letters of the name, and sometimes also the titles, were placed about this cross. By degrees the custom changed, and they invented other marks; as for example, the sign of Charlemagne was thus:

R
A
K—S
V
L

They sometimes added also the dates and epoch of the signature, the feasts of the church, the days of the calendar, and other like matters. The successive corruption of the Latin language, the style and orthography of each age, as well as their different titles and forms; the abbreviations, accentua-

tion, and punctuation, and the various methods of writing the diphthongs; all these matters united, form so many characters and marks by which the authenticity of a diploma is to be known.

The seal annexed to a diploma was anciently of white wax, and artfully imprinted on the parchment itself. It was afterward pendent from the paper, and inclosed in a box or case, which they called *bullæ*. There are some also that are stamped on metal, and even on pure gold. When a diploma bears all the characters that are requisite to the time and place where it is supposed to be written, its authenticity is not to be doubted; but, at the same time, we cannot examine them too scrupulously, seeing that the monks and priests of former ages have been very adroit in making of counterfeits; and the more, as they enjoyed the confidence of princes and statesmen, and were even sometimes in possession of their rings or seals.

With regard to manuscripts that were wrote before the invention of printing, it is necessary (1) to know their nature, their essential qualities, and matter; (2) to be able to read them freely, and without error; (3) to judge of their antiquity by those characters which we have just mentioned with regard to the diplomas; and (4) to render them of use in the sciences. As there are scarce any of the ancient codes now remaining (see par. 2.) wrote on the Egyptian paper, or on wood, ivory, &c. we have only to consider those that are written on parchment or vellum (*membraneæ*), and such as were wrote on our paper (*chartaceæ*). The former of these are in most esteem. With regard to the character, these codes are written either in square and capital letters, or in half square, or round and small letters. Those of the first kind are the most ancient. There are no intervals between the words, no letters different from the others at the beginning of any word, no points, nor any other distinction. The codes which are wrote in letters that are half square, resemble those we have in Gothic characters, as well for the age as the form of the letters. Such as were wrote in round letters are not so ancient as the former, and do not go higher than the ninth or tenth century. These have spaces between the words, and some punctuation. They are likewise not so well wrote as the preceding, and are frequently disfigured with comments. The codes are divided, according to the country, into Lombard, Italian, Gaulic, Franco-Gaulic, Saxon, Anglo-Saxon, &c.

In the ancient Greek books, they frequently terminated the periods of a discourse, instead of all other division, by lines; and these divisions were called, in Latin, *versus*, from *vertendo*: for which reason these lines are still more properly named *versus* than *lineæ*. At the end of a work, they put down the number of verses of which it consisted, that the copies might be more easily collated: and it is in this sense we are to understand Trebonius, when he says, that the pandects contain 150,000 *pene versus*. These codes were likewise *vel probe vel deterioris notæ*, more or less perfect, not only with regard to the calligraphy or beauty of the character, but to the correction of the text also.

It is likewise necessary to observe, in ancient codes, the abbreviations, as they have been used in different centuries. Thus, for example, A. C. D. signifies, Aulus Caius Decimus; Ap. Cn. Appius Cneius; Aug. Imp. Augustus Imperator. The characters that are called *notæ*, are such as are not to be found in the alphabet; but which, notwithstanding, signify certain words. All these matters are explained in a copious manner by Vossius, and in the Chronicon Gotvicensæ. Lastly, the learned divide all the ancient codes into *codices minus raros, rariores, editos, & anecdotos*. The critical art is here indispensably necessary: its researches, moreover, have no bounds; and the more, as the use of it augments every

day, by the discoveries that are made in languages, and by the increase of erudition.

DISSENTIS, a town of Switzerland, capital of a jurisdiction of the same name, in the country of the Grisons, with an abbey founded in the seventh century. It is situate near the sources of the Rhone, 10 miles S.S.W. of Ilanz.

DISMAL SWAMP, a marshy tract on the coast of N. Carolina, 50 miles long and 30 broad. It occupies the whole country between Albemarle Sound and Pamlico Sound.

DISPOSITION, in Scots law, is that deed or writing which contains the sale or grant of any subject: when applied to heritable subjects, it in some cases gets the name of *charter*, which differs from a disposition in nothing else than a few immaterial forms.

DISS, a town in Norfolk, with a market on Friday. It is seated on the river Waveney, on the side of a hill; and at the W. end of the town is a large muddy lake, abounding with eels. Here are manufactures of sail-cloth, linen cloth, hose, and stays. It is 19 miles S. of Norwich, and 92 N.N.E. of London. Long. 1. 9. E. Lat. 52. 25. N.

DISSEN, or **TISSEN**, a town of Germany, in the bishopric of Osnabrug, where are salt works belonging to the Elector of Hanover. It is 16 miles S.E. of Osnabrug.

DISSENTERS (*Encycl.*). The first dissenters from the establishment were called **PURITANS**, and generally adopted the presbyterian form of church government. Robert Brown, a disaffected minister, in the reign of Elizabeth, instituted a new sect, which afterwards rose into considerable consequence, under the title of **INDEPENDENTS**. The presbyterians at present are but very few; for most, if not all the dissenting congregations in England, are independent of any synodical assembly. There is another numerous and respectable class of dissenters called baptists, but a consideration of their state and principles already appears in another place.

At the time of the act of uniformity in 1662, and for many years afterwards, the non-conformists or dissenters were doctrinally Calvinists. About the close of the last century, Arianism began to shew itself among them, and when Dr. Clarke started the controversy on the Trinity, it spread more rapidly among the dissenters than in the established church. Most of the considerable congregations declined from the Calvinistical sentiments of their ancestors, and fell into Arian or Socinian principles. Some, however, while they adopted the Arminian doctrines, admitted that of the trinity, though it is doubtful whether most of these were not Semi-arians. All those who thus gave up the creed of the old nonconformists have assumed the title of rational dissenters, because they assert the full use of human reason on matters of faith. Socinianism was rather a private matter of opinion among particular ministers and others, till Dr. Lardner openly espoused it. Dr. Priestley's zeal and talents gave it considerable circulation; and the secession of Mr. Lindsey from the established church gave rise to a Socinian congregation in Essex-street, wherein a liturgy altered from that of the church of England is used. This congregation is now under the care of Dr. Diney, another clergyman who has seceded from the church on account of his principles. The number of Socinians, however, is far from being large; and the meeting in Essex-street is but thinly attended. Since the rise of methodism many independent congregations have returned to Calvinistic principles, and many new places of worship have been erected for those of that persuasion. Several of the preachers in Mr. Wesley's and Mr. Whitfield's connections, and also those who were brought up at the expense of the late Counts of Huntingdon, have forsaken the itinerant course of life, and settled as ministers of congregations on the independent plan. It happens that among these, few are found who possess the ad-

vantages of education; but they in general appear earnest in their manner, and ready in their eloquence. The plain and familiar mode of address seems best suited to common hearers, and in this respect the man of moderate talents may possess superior advantages to the man of erudition. The system of the rational Christians is, indifferently calculated to operate upon the minds of the ordinary part of mankind; and those of a more assuaging intellect will only be prepared by it for the reception of positive infidelity.

Dr. Priestley, before his departure for America, lamented greatly the rapid decline of Socinianism; and there is no ground to believe that the case has been altered since. Yet the dissenters at large, it is imagined, have not decreased. If old congregations have dissolved, new ones have arisen of a different complexion; and it deserves remark, that many who acquired religious sentiments and habits of seriousness by attending some favourite and popular preacher in the establishment, have forsaken the church on his death, and joined the dissenters. This circumstance has often happened, and is generally owing to the doctrine preached by the succeeding minister being different from that to which the people have been long accustomed. Much, indeed, may be attributed to the capriciousness of hearers; but, in general, persons of a serious turn, who have been in constant attendance on the service of the church, will not leave it without some reason of this sort.

The dissenters have lately distinguished themselves by instituting, in conjunction with the methodists, a missionary society. The design of propagating the gospel is doubtless highly commendable, and forms, in fact, a Christian duty. But in this, as in all other great undertakings, much prudence, wisdom, and humility, are requisite. Whether these have been evidenced in this famous project is a matter of some question. Passing by all the intermediate regions of barbarism, the managers of this institution directed their first attention to the distant isles of the southern ocean. The persons sent out on this arduous work were mostly mechanics, and such as had little acquaintance with human nature, the various customs and characters of mankind, and the arts of insinuating address, calculated to effect a great change in the manners of the people to whom they were sent. Some disappointment attended this first mission; but in another which was afterwards undertaking among the Hottentots, by the Dutch, from the cape of Good Hope (under the direction of the London society), great success, it is said, has been experienced, and there is a prospect of much good being done in that quarter. There is evidently, however, much of ostentation in the procedure of this society. Their journals are published in a most pompous manner, and an elegant print has been engraved representing the interview of the missionaries at Otahite with the chiefs. This conduct is ridiculous before the event of the mission is exactly known, and that cannot be expected suddenly to take place. These gentlemen seem to think that the divine power and direction are surely on their side, and, therefore, that they have no reason to doubt of success. This is not acting as the apostles did, nor in the manner which their Master commanded them.

The same zealous persons have recently been stirred up to undertake what they call missions at home; and, in consequence, many itinerant preachers have gone into various parts of the country. This may, in some cases, do good, but the scheme ought to put the clergy on their guard; and the only way by which they can counteract the itinerants is to out-preach, out-live, and out-labour them. The care and faithfulness of the established ministers will soon render the officiousness of the others of none effect. The principal seminaries of education for the ministry among the dissenters are at Hackney, Northampton, Manchester, Homerton, Wrexham

(Denbighshire), Swansea (South Wales), Hoxton, Taunton, and Davenport.

DIVING (*Encycl.*). The following description of a submarine vessel, or *diving-machine*, invented by Mr. Bushnell, of Connecticut, is given in the Transactions of the American Philosophical Society.

The external shape of the sub-marine vessel bore some resemblance to two upper tortoise shells of equal size, joined together; the place of entrance into the vessel being represented by the opening made by the swell of the shells, at the head of the animal. The inside was capable of containing the operator, and air sufficient to support him thirty minutes without receiving fresh air. At the bottom, opposite to the entrance, was fixed a quantity of lead for ballast. At one edge, which was directly before the operator, who sat upright, was an oar for rowing forward or backward. At the other edge was a rudder for steering. An aperture, at the bottom, with its valve, was designed to admit water, for the purpose of descending; and two brass forcing-pumps served to eject the water within, when necessary for ascending. At the top, there was likewise an oar, for ascending or descending, or continuing at any particular depth. A water-gauge, or barometer, determined the depth of descent, a compass directed the course, and a ventilator within supplied the vessel with fresh air, when on the surface.

The entrance into the vessel was elliptical, and so small as barely to admit a person. This entrance was surrounded with a broad elliptical iron band, the lower edge of which was let into the wood of which the body of the vessel was made, in such a manner, as to give its utmost support to the body of the vessel against the pressure of the water. Above the upper edge of this iron band there was a brass-crown, or cover, resembling a hat with its crown and brim, which shut water-tight upon the iron band: the crown was hung to the iron band with hinges, so as to turn over sideways, when opened. To make it perfectly secure when shut, it might be screwed down upon the band by the operator, or by a person without.

There were in the brass crown three round doors, one directly in front, and one on each side, large enough to put the hand through. When open they admitted fresh air; their shutters were ground perfectly tight into their places with emery, hung with hinges, and secured in their places when shut. There were likewise several small glass windows in the crown, for looking through, and for admitting light in the day-time, with covers to secure them. There were two air pipes in the crown. A ventilator within drew fresh air through one of the air pipes, and discharged it into the lower part of the vessel; the fresh air introduced by the ventilator expelled the impure light air through the other air pipe. Both air pipes were so constructed, that they shut themselves whenever the water rose near their tops, so that no water could enter through them, and opened themselves immediately after they rose above the water.

The vessel was chiefly ballasted with lead fixed to its bottom; when this was not sufficient, a quantity was placed within, more or less, according to the weight of the operator; its ballast made it so stiff, that there was no danger of upsetting. The vessel with all its appendages, and the operator, was of sufficient weight to settle at very low in the water. About two hundred pounds of the lead, at the bottom for ballast, would be let down forty or fifty feet below the vessel; this enabled the operator to rise instantly to the surface of the water, in case of accident.

When the operator would descend, he placed his foot upon the top of a brass valve, depressing it, by which he opened a large aperture in the bottom of the vessel, through which the water entered at his pleasure; when he had admitted a suffi-

cient quantity, he descended very gradually; if he admitted too much, he ejected as much as was necessary to obtain an equilibrium, by the two brass forcing pumps, which were placed at each hand. Whenever the vessel leaked, or he would ascend to the surface, he also made use of these forcing pumps. When the skilful operator had obtained an equilibrium, he could row upward, or downward, or continue at any particular depth, with an oar, placed near the top of the vessel, formed upon the principle of the screw, the axis of the oar entering the vessel; by turning the oar one way he raised the vessel, by turning it the other way he depressed it.

A glass tube eighteen inches long, and one inch in diameter, standing upright, its upper end closed, and its lower end, which was open, screwed into a brass pipe, through which the external water had a passage into the glass tube, served as a water-gauge or barometer. There was a piece of cork, with phosphorus on it, put into the water-gauge. When the vessel descended the water rose in the water-gauge, condensing the air within, and bearing the cork, with its phosphorus, on its surface. By the light of the phosphorus, the ascent of the water in the gauge was rendered visible, and the depth of the vessel under water ascertained by a graduated line.

An oar, formed upon the principle of the screw, was fixed in the fore part of the vessel; its axis entered the vessel, and being turned one way, rowed the vessel forward, but being turned the other way rowed it backward; it was made to be turned by the hand or foot.

A rudder, hung to the hinder part of the vessel, commanded it with the greatest ease. The rudder was made very elastic, and might be used for rowing forward. Its tiller was within the vessel, at the operator's right hand, fixed, at a right angle, on an iron rod, which passed through the side of the vessel; the rod had a crank on its outside end, which commanded the rudder, by means of a rod extending from the end of the crank to a kind of tiller, fixed upon the left hand of the rudder. Raising and depressing the first-mentioned tiller turned the rudder as the case required.

A compass marked with phosphorus directed the course, both above and under the water; and a line and lead sounded the depth when necessary.

The internal shape of the vessel, in every possible section of it, verged towards an ellipsis, as near as the design would allow, but every horizontal section, although elliptical, yet as near to a circle as could be admitted. The body of the vessel was made exceedingly strong; and to strengthen it as much as possible, a firm piece of wood was framed, parallel to the conjugate diameter, to prevent the sides from yielding to the great pressure of the incumbent water, in a deep immersion. This piece of wood was also a seat for the operator.

Every opening was well secured. The pumps had two sets of valves. The aperture at the bottom, for admitting water, was covered with a plate, perforated full of holes to receive the water, and prevent any thing from choking the passage, or stopping the valve from shutting. The brass valve might likewise be forced into its place with a screw, if necessary. The air pipes had a kind of hollow sphere, fixed round the top of each, to secure the air-pipe valves from injury: these hollow spheres were perforated full of holes, for the passage of the air through the pipes: within the air-pipes were shutters to secure them, should any accident happen to the pipes, or the valves on their tops.

Wherever the external apparatus passed through the body of the vessel, the joints were round, and formed by brass pipes, which were driven into the wood of the vessel, the holes through the pipes were very exactly made, and the iron rods, which passed through them, were turned in a lathe to

fit them; the joints were also kept full of oil, to prevent rust and leaking. Particular attention was given to bring every part, necessary for performing the operations, both within and without the vessel, before the operator, and as conveniently as could be devised; so that every thing might be found in the dark, except the water-gauge and the compass, which were visible by the light of the phosphorus, and nothing required the operator to turn to the right hand, or to the left, to perform any thing necessary.

The inventor next pursues the subject under the following heads:—

1. Description of a magazine, and its appendages, designed to be conveyed by the sub-marine vessel to the bottom of a ship.—In the fore part of the brim of the crown of the sub-marine vessel, was a socket, and an iron tube, passing through the socket; the tube stood upright, and could slide up and down in the socket, six inches: at the top of the tube was a wood-screw, fixed by means of a rod, which passed through the tube, and screwed the wood-screw fast upon the top of the tube: by pulling the wood-screw up against the bottom of a ship, and turning it at the same time, it would enter the planks; driving would also answer the same purpose; when the wood-screw was firmly fixed, it could be cast off by unscrewing the rod, which fastened it upon the top of the tube.

Behind the sub-marine vessel was a place, above the rudder, for carrying a large powder magazine; this was made of two pieces of oak timber, large enough, when hollowed out, to contain 150 pounds of powder, with the apparatus used in firing it, and was secured in its place by a screw, turned by the operator. A strong piece of rope extended from the magazine to the wood-screw above mentioned, and was fastened to both. When the wood-screw was fixed, and to be cast off from its tube, the magazine was to be cast off likewise by unscrewing it, leaving it hanging to the wood-screw; it was lighter than the water, that it might rise up against the object, to which the wood-screw and itself were fastened.

Within the magazine was an apparatus, constructed to run any proposed length of time, under twelve hours; when it had run out its time, it unpointed a strong lock resembling a gun lock, which gave fire to the powder. This apparatus was so jointed, that it could not possibly move, till, by casting off the magazine from the vessel, it was set in motion.

The skilful operator could swim so low on the surface of the water, as to approach very near a ship, in the night, without fear of being discovered, and might, if he chose, approach the stem or stern above water, with very little danger. He could sink very quickly, keep at any depth he pleased, and row a great distance in any direction he desired, without coming to the surface, and when he rose to the surface, he could soon obtain a fresh supply of air, when, if necessary, he might descend again, and pursue his course.

2. Experiments made to prove the nature and use of a sub-marine vessel.—The first experiment made was with about two ounces of gunpowder, which were exploded four feet under water, to prove to some of the first persons in Connecticut that powder would take fire under water.

The second experiment was made with two pounds of powder, inclosed in a wooden bottle, and fixed under a hoghead, with a two-inch oak plank between the hoghead and the powder; the hoghead was loaded with stones as deep as it could swim; a wooden pipe descending through the lower head of the hoghead, and through the plank, into the powder contained in the bottle, was primed with powder. A match put to the priming, exploded the powder, which produced a very great effect, rending the plank into pieces; demolishing the hoghead; and casting the stones and the ruins of the

hoghead, with a body of water, many feet into the air, to the astonishment of the spectators. This experiment was likewise made for the satisfaction of the gentlemen above mentioned.

There were afterwards made many experiments of a similar nature, some of them with large quantities of powder; they all produced very violent explosions, much more than sufficient for any purpose had in view.

In the first essays with the sub-marine vessel the inventor took care to prove its strength, to sustain the great pressure of the incumbent water, when sunk deep, before he trusted any person to descend much below the surface: and he never suffered any person to go under water without having a strong piece of rigging made fast to it, until he found him well acquainted with the operations necessary for his safety. After that he made him descend, and continue at particular depths, without rising or sinking, row by the compass, approach a vessel, go under her, and fix the wood-screw mentioned before, into her bottom, &c. until he thought him sufficiently expert to put any design into execution.

It required many trials to make a person of common ingenuity a skilful operator: the first employed was very ingenious, and made himself master of the business, but was taken sick in the campaign of 1776, at New York, before he had an opportunity to make use of his skill, and never recovered his health sufficiently afterwards.

3. Experiments made with a sub-marine vessel.—After various attempts to find an operator to his wish, Mr. Buthnell sent one, who appeared more expert than the rest, from New York, to a fifty-gun ship, lying not far from Governor's Island. He went under the ship, and attempted to fix the wooden screw into her bottom, but struck, as he supposes, a bar of iron, which passes from the rudder hinge, and is fixed under the ship's quarter. Had he moved a few inches, which he might have done, without rowing, he would probably have found wood where he might have fixed the screw; or, if the ship were sheathed with copper, he might easily have pierced it: but not being well skilled in the management of the vessel, in attempting to move to another place, he lost the ship; after seeking her in vain, for some time, he rowed some distance, and rose to the surface of the water, but found day-light had advanced so far, that he durst not renew the attempt. The adventurer said that he could easily have fastened the magazine under the stem of the ship, above water, as he rowed up to the stern, and touched it before he descended. Had he fastened it there, the explosion of 150 pounds of powder (the quantity contained in the magazine), must have been fatal to the ship. In his return from the ship to New York, he passed near Governor's Island, and thought he was discovered by the enemy on the island; being in haste to avoid the danger he feared, he cast off the magazine, as he imagined it retarded him in the swell, which was very considerable. After the magazine had been cast off one hour, the time the internal apparatus was set to run, it blew up with great violence.

Afterwards, there were two attempts made in Hudson's river, above the city, but they effected nothing. One of them was by the afore-mentioned person. In going towards the ship, he lost sight of her, and went a great distance beyond her: when he at length found her, the tide ran so strong, that, as he descended under water, for the ship's bottom—it swept him away. Soon after this, the enemy went up the river, and pursued the boat which had the sub-marine vessel on board; and sunk it with their shot. "Though," says Mr. Buthnell, "I afterwards recovered the vessel, I found it impossible, at that time, to prosecute the design any

further. I had been in a bad state of health, from the beginning of my undertaking, and was now very unwell; the situation of public affairs was such, that I despaired of obtaining the public attention, and the assistance necessary. I was unable to support myself, and the persons I must have employed, had I proceeded. Besides, I found it absolutely necessary, that the operators should acquire more skill in the management of the vessel, before I could expect success: which would have taken up some time, and made no small additional expence. I therefore gave over the pursuit for that time, and waited for a more favourable opportunity, which never arrived."

4. Other experiments made with a design to fire shipping.—In the year 1777, Mr. Buthnell made an attempt from a whale-boat against the Cerberus frigate, then lying at anchor between Connecticut river and New London, by drawing a machine against her side, by means of a line. The machine was loaded with powder, to be exploded by a gun-lock, which was to be unimpined by an apparatus, to be turned by being brought along-side of the frigate. This machine fell in with a schooner at anchor, astern of the frigate, and concealed from his sight. By some means or other it was fired, and demolished the schooner and three men; and blew the only one left alive over-board, who was taken up very much hurt.

After this he fixed several kegs under water, charged with powder, to explode, upon touching any thing, as they floated along with the tide: he set them afloat in the Delaware, above the English shipping at Philadelphia, in December, 1777. "I was unacquainted," says he, "with the river, and obliged to depend upon a gentleman very imperfectly acquainted with that part of it, as I afterwards found. We went as near the shipping as he durst venture; I believe the darkness of the night greatly deceived him, as it did me. We set them adrift, to fall with the ebb, upon the shipping. Had we been within sixty rods I believe they must have fallen in with them immediately, as I designed; but, as I afterwards found, they were set adrift much too far distant, and did not arrive until after being detained some time by frost, they advanced in the day-time, in a dispersed situation, and under great disadvantages. One of them blew up a boat with several persons in it, who imprudently handled it too freely, and thus gave the British that alarm which brought on the battle of the Kegs."

DIU, an island at the entrance of the gulf of Cambay, in the Deccan of Hindoostan, three miles long and one broad. On it is a large fortified town of the same name, built of free-stone and marble; and it contains some fine churches, erected by the Portuguese, about the time they took possession of the island in 1515. The trade of the town, once so important, is almost entirely removed to Surat. It is 180 miles W. by S. of Surat, and 200 N.W. of Bombay. Long. 69. 52. E. Lat. 20. 43. N.

DIURESIS (from *uror, urine*). An excretion of urine.

DIXAN, the first town in Abyssinia, on the side of Tarenta. It is built on the top of a conical hill; a deep valley surrounds it like a trench, and the road winds spirally up the hill till it ends among the houses. The inhabitants consist of Moors and Christians, whose only trade is the selling of children. The Christians bring such as they have stolen in Abyssinia to Dixan, where the Moors receive them, and carry them to a market at Masuah, whence they are sent to Arabia or India. The priests of the province of Tigre are openly concerned in this infamous traffic. Long. 40. 7. E. Lat. 14. 57. N.

DIXMUDE, a town of Austrian Flanders, which has been often taken, the last time by the French in 1794. It is cele-

brated for its excellent butter, and seated on the river Yperlee, ten miles N.W. of Ypres. Long. 2. 57. E. Lat. 51. 2. N.

DIZIER, St. a town of France, in the department of Upper Marne, seated on the Marne, where it begins to be navigable for boats, fifteen miles S.E. of Vitri-le-François. Long. 4. 54. E. Lat. 48. 35. N.

DNIEPER, anciently the Boristhenes, a large river of Russia, which rises in the government of Smolensko, and flowing in a southerly direction, enters the Black Sea, between Cherfon and Oczakow. From its source to its mouth, it now flows entirely through the Russian dominions; and through this whole course, of above 800 miles, its navigation is only once interrupted by a series of cataracts, which begin below the mouth of the Samara, and continue for above forty miles; but these may be passed in spring, without much hazard, even by loaded barks. In other seasons of the year, the goods are landed at Kernenik, opposite the mouth of the Samara, and transported forty miles by land to Kitchkale, six miles from the fortrefs of Alexandrowk, where they are again embarked, and defend the stream to Cherfon.

DNIESTER, a fine river, which rises in Galicia, in Austrian Poland, and visits Chockzim, dividing Podolia from Moldavia; it then separates Bessarabia from the Russian government of Catharinenslat, and having watered Bender, falls into the Black Sea, between the mouths of the Dnieper and the Danube.

DOBELIN, a town of Courland, twenty miles S.W. of Mittau. Long. 23. 35. E. Lat. 56. 28. N.

DOBRZIN, a town of Poland, in Masovia, capital of a territory of the same name, seated on a rock, near the Vistula, fourteen miles N.W. of Plockiko. Long. 19. 5. E. Lat. 52. 54. N.

DOCKUM, a town of the United Provinces, in W. Friesland; at the mouth of the river Ee, ten miles N.E. of Lewarden. Long. 5. 41. E. Lat. 53. 18. N.

DOBART (Denys), physician of Lewis XIV. and member of the French Academy of Sciences, was born at Paris in 1634. Among other things, he is the author of a *Statica Medicina Gallica*: and he greatly cultivated the theory of insensible perspiration, treading closely in the steps of Sanctoarius. He made the following experiment upon himself. Upon the first day of Lent 1677, he weighed 116 pounds and one ounce; after undergoing the discipline and abstinence of Lent, he weighed, on Easter Eve, no more than 107 pounds and twelve ounces. He lost during this season, therefore, eight pounds and five ounces. These attentions he is said to have continued for 33 years. He died in 1707, universally regretted. He was, says Fontenelle, of a most religious and serious character, yet not austere and frowning. Guy Patin, who was as covetous of eulogies, as he was prodigal of satire, called him *monstrum sine vitio*, a prodigy of wisdom and science without any defect.

Claude Dobart, his son, who was also first physician to the king, died at Paris in 1720, and left Notes sur l'Histoire Générale des Drogues, par Pierre Pomey.

DODSWORTH (Roger), son of Matthew Dodsworth, rector of York cathedral, and chancellor to Archbishop Matthews, was born July 24, 1585, at Newton-Grange, in the parish of St. Oswald, in Rydale, Yorkshire; he was a man of wonderful industry, but less judgment; always collecting and transcribing, but never published any thing. He was esteemed as an indefatigable collector of the antiquities of York, who undertook and executed a work, which, to the antiquaries of the present age, would have been the stone of Tyldes. One hundred and twenty-two volumes of his own writing, besides original MSS. which he had obtained from several hands,

making all together 162 volumes folio, now lodged in that grand repository of our ancient monuments the Bodleian Library at Oxford, are lasting memorials what this country owes to him, as the two volumes of the *Monasticon* (which though published under his and Dugdale's names conjointly, were both collected and written totally by him) will immortalise that extensive industry which has laid the whole kingdom under obligation. The patronage of General Fairfax preserved this treasure, and bequeathed it to the library where it is now lodged. Fairfax preserved also the fine windows of York cathedral; and when St. Mary's tower, in which were lodged innumerable records, both public and private, relating to the northern parts, was blown up during the siege of York, he gave money to the soldiers who could save any scattered papers, many of which are now at Oxford; though Dodsworth had transcribed and abridged the greatest part before. Fairfax allowed Dodsworth a yearly salary to preserve the inscriptions in churches.

Fairfax died in 1671; his nephew Henry Fairfax, Dean of Norwich, gave Roger Dodsworth's 160 volumes of collections to the university of Oxford; but the MSS. were not brought thither till 1673, and then in wet weather, when Wood with much difficulty obtained leave of the vice-chancellor to have them brought into the muniment-room in the school-tower, and was a month drying them on the leads. Dodsworth died in August 1654, and was buried at Rufford, Lancashire.

DOEL, a town of Dutch Flanders, on the river Scheld, opposite Lillo, nine miles N.W. of Antwerp. Long. 4. 15. E. Lat. 51. 17. N.

DOG (*Encycl.*) By stat. 38 Geo. III. c. 41. f. 2. there shall be paid, from and after April 5, 1798, in lieu of the old duties repealed, the following rates and duties for every dog of the several descriptions herein-after mentioned, kept by or for the use of any person:

Number of dogs.	Duties payable for each dog.
For every greyhound, hound, pointer, setting dog, spaniel, lurcher, or terrier, and for every dog of whatever description or denomination the same may be, where any person shall keep two or more dogs	£. 0 6 0
For any dog (not being a greyhound, hound, setting dog, spaniel, lurcher, or terrier) kept by or for the use of any person inhabiting a dwelling-house, affixed to any of the duties on houses, windows, or lights, or on inhabited houses, where one such dog and no more shall be kept by or for the use of such person	£. 0 4 0
The said duties to be paid by the persons respectively keeping such dogs, or for whose use the same shall be kept, and to be subject to all the exemptions contained in any act in force; and also to the regulations contained in the act of the 36th George III. which act contains the following provisions:—	

1st, That the duty shall not extend to dogs not six months old, the proof of which is to lie on the owner, on an appeal to the commissioners.

2dly, If any person shall be desirous of compounding for the number of hounds by him kept, and shall give notice thereof to the collector, and shall pay within thirty days after April 5, yearly, the sum of 24l. such person shall not be liable to be assessed in respect of any hounds by him kept in the preceding year; and if they are kept in two or more parishes, he shall give notice in which parish such composition is intended to be made. 38 Geo. III. c. 41. f. 2.

DOGADO, a province of the late Venetian states, in

which is the capital. It is bounded on the E. by the gulf of Venice, on the S. by Polesino, on the W. by Paduano, and on the north by Trevifano. It comprehends many small islands near it, called the LAGUNES of VENICE.

DOGGET (Thomas), an author and an actor, was born in Castle-street, Dublin, and made his first theatrical attempt on the stage of that metropolis; but not meeting with the encouragement there that his merit undoubtedly deserved, he came over to England, and entered himself in a travelling company, but from thence very soon was removed to London, and established in Drury-Lane and Lincoln's-Inn-Fields theatres, where he was universally liked in every character he performed, but those in none more conspicuously than those of Fonderwife in the Old Bachelor, and Ben in Love for Love, which Mr. Congreve, with whom he was a very great favourite, wrote in some measure with a view to his manner of acting.

In a few years after he removed to Drury-Lane theatre, where he became joint-manager with Wilks and Cibber, in which situation he continued, till on a disgust he took in the year 1712, at Mr. Booth's being forced on them as a sharer in the management, he threw up his part in the property of the theatre, though it was looked on to have been worth 1000*l.* per annum. He had, however, by his frugality, saved a competent fortune to render him easy for the remainder of his life, with which he retired from the hurry of business in the very meridian of his reputation. As an actor he had great merit, and his contemporary Cibber informs us that he was the most original and the strictest observer of nature, of any actor of his time. His manner, though borrowed from none, frequently served for a model to many; and he possessed that peculiar art which so very few performers are masters of, viz. the arriving at the perfectly ridiculous, without stepping into the least impropriety to attain it. And so extremely careful and skilful was he in the dressing of his characters to the greatest exactness of propriety, that the least article of what he wore seemed in some measure to speak and mark the different humour he presented;—a necessary care in a comedian, in which many performers are but too remiss. He died Sept. 22, 1721.

Dogget, in his political principles, was a "Whig up to the head and ears;" and so strictly was he attached to the interests of the house of Hanover, that he never let slip any occasion that presented itself of demonstrating his sentiments in that respect. One instance, among others, is well known, which is, that the year after George I. came to the throne, this performer gave a waterman's coat and silver badge, to be rowed for by six watermen, on the 1st day of August, being the anniversary of that king's accession to the throne. And at his death bequeathed a certain sum of money, the interest of which was to be appropriated annually, for ever, to the purchase of a like coat and badge, to be rowed for in honour of that day. Which ceremony is every year performed on the 1st of August, the claimants setting out on a signal given at that time of the tide when the current is strongest against them, and rowing from the Old Swan near London-Bridge, to the White Swan at Chelsea.

As a writer, Dogget has left behind him only one comedy, which has not been performed in its original state for many years, entitled, *The Country Wake*. C. 1696, 4to. It has been altered however into a ballad farce, which frequently makes its appearance under the title of, *Flora, or Hob in the Well*.

DOL, a town of France, in the department of Ille and Vilaine. It was lately an episcopal see, and is situate in a mo-

rafs, five miles from the sea, and 21 S.E. of St. Malo. Long. 1. 41. W. Lat. 48. 33. N.

DOLCE-AQUA, a town of Piedmont, capital of a marquise of the same name, with a castle. It is seated on the Nervia, five miles N. of Vintimiglia. Long. 7. 42. E. Lat. 43. 58. N.

DOLCIGNO, a strong town of Albania, with a bishop's see, a good harbour, and a citadel. It is seated on the Drino, 10 miles S.E. of Antivari. Long. 19. 25. E. Lat. 42. 12. N.

DOLE, a town of France, in the department of Jura, seated on the river Doubs, 35 miles S.W. of Besançon. Long. 5. 38. E. Lat. 47. 6. N.

DOLET (Stephen), a very learned man, and memorable for being burnt at Paris for his opinions in religion, was born at Orleans in 1508. He applied himself to reform the French language, and polish it from the barbarity with which it was incrufted; nay, what is more, as Baillet tells us, he thought himself destined by Heaven to this task, and let himself to compose some treatises on the matter; but the public, it seems, was not disposed to listen to his pretended vocation. He wrote some Latin and French verses, which in Bayle's judgment are not amiss; for as to the severity and contempt with which Julius Scaliger treated him and his poetry, it has no weight with Bayle, who imputes it to a private motive of resentment, which Scaliger had conceived against Dolet, for interfering with him in defending the Ciceronians against the ridicule of Erasmus. Dolet's attempts to promote good literature gained him a great share in the affection of Castellani, who was a very learned prelate, and much beloved by Francis I. whose natural son, by the way, Dolet is said to have been; though Bayle is of opinion, that Francis was too young, when Dolet was born, to have been his father. We must not forget to observe, that Dolet, though a learned man and an author, was in the mean time a printer and bookseller at Lyons, and printed some of his own writings. He would have printed the French translation of most of Plato's works, which he himself had made, if he had lived; this translation however he must have made from the Latin, which he understood well, and not from the Greek, which he is said not to have understood at all. The first time he was imprisoned for religion, his friend Castellani interceded for him, and got him released, upon his promising to be a good Catholic. But Dolet relapsing into his former licentious way, nobody durst appear for him when he was imprisoned the second time: so that, being abandoned to the fury of the inquisitors, he was condemned to be burnt to death for atheism, and not for Lutheranism as some have declared: this punishment he underwent August 3, 1546, which was the day of his nativity. A letter was published by Almevoen, in his *Amicitiae Theologico-Philologicae*, printed at Amsterdam in 1694, which testifies, that Dolet recommended himself to the holy Virgin, and to St. Stephen, a little before he was strangled, but these kind of testimonies are much to be suspected.

DOLGELLY, a town in Merionethshire, with a market on Tuesday. It is seated on the river Avon, in a vale so called, and at the foot of the great rock Cader-Idris, which is extremely high. It has a good manufacture of Welsh cotton, and is 31 miles N.W. of Montgomery, and 205 of London. Long. 9. 48. W. Lat. 52. 42. N.

DOLLART BAY, a large gulf, separating E. Friedland, in Germany, from Groningen, one of the United Provinces.

DOMAZLIZE, a town of Bohemia, in the circle of Pilsen, remarkable for a battle fought between the crusaders and the Hussites in 1466, to the great disadvantage of the former. It was taken by the Swedes in 1541. It is seated on the river Cadzuz, 17 miles S. of Pilsen.

DOMBACA, a small island near the coast of Ava, in the Bay of Bengal. Long. 94. 35. E. Lat. 17. 32. N.

DOMBES, a late principality and small country of France, in Burgundy, of which Trevoix was the capital. It is now part of the department of Ain.

DOMBROWAZ, a town of Poland, in the palatine of Lemberg, 60 miles S.W. of Lemberg.

DOMFRONT, a town of France, in the department of Orne, seated on a craggy rock, which has a large cleft from the summit to the base, through which flows the little river Varenne. It is 35 miles N.W. of Alençon. Long. 0. 43. W. Lat. 48. 38. N.

DOMICILE, in Scots law, is the dwelling-place where a person lives with an intention to remain.

DOMINIUM EMINENS, in Scots law, that power which the state or sovereign has over private property, by which the proprietor may be compelled to sell it for an adequate price where public utility requires.

DOMINIUM DIRECTUM, in Scots law, the right which a superior retains in his lands, notwithstanding the feudal grant to his vassal.

DOMINIUM UTILE, in Scots law, the right which the vassal acquires in the lands by the feudal grant from his superior.

DOMINO, St. one of the Tremiti Islands, in the gulf of Venice, 15 miles from the coast of Naples.

DOMITZ, a town of Mecklenberg Schwerin, with a fort, seated at the confluence of the Elbe and Elve, 25 miles S. of Schwerin. Long. 11. 41. E. Lat. 53. 15. N.

DOMMEL, a river of Brabant, which receives the Aa below Bois-le-Duc, and then falls into the Meuse.

DOMO-D'OSSOLA, a town of Italy, in the duchy of Milan, with a castle, seated on the Tosa, at the foot of the Alps, 20 miles N. of Varallo.

DOMPAIRE, a town of France, in the department of the Voiges, formerly the residence of the kings of Austrasia and dukes of Lorraine, 10 miles W.N.W. of Epinal.

DOMREMY-LA-PUCELLE, a village of France, in the department of Meuse, remarkable for the birth of Joan of Arc, the Maid of Orleans. It is seated on the Meuse, five miles from Neufchateau.

DON, a river in Yorkshire, which waters Sheffield, Rotherham, and Doncaster, and joins the Aire near its termination with the Ouse.

DONAGHADEE, a sea-port of Ireland, in the county of Down, 20 miles W. by S. of Port Patrick, in Scotland, between which two places a packet-boat sails every day.

DONATUS (JEROM), a nobleman of Venice, who died in the beginning of the 16th century. He was very useful to his country; served it as a commander more than once: and was the means of reconciling that republic and pope Julius II. though he had the misfortune to be carried off by a violent fever at Rome before the treaty was concluded between them. He was also a man of learning: and published a translation of Alexander Aphrodisæus de Anima. His letters are likewise well written; and he made Erasmus say of him, that he was capable of performing any thing in the way of learning, if his mind had not been dissipated by other employments. Pictorius Valerianus has placed him in the list of unfortunate learned men, for which he gives three reasons: first, because his domestics obeyed him ill; secondly, because he did not live to see the happiness which would arise to his country from the conclusion of his treaty; thirdly, because a great many books, which he had written to immortalise his name, remained unpublished. Now, as it seems to us, the first of these grievances might have been redressed; the second was no grievance at all, since he had actually attained his point; and, thirdly, we cannot think it any misfortune to a dead man,

that such a number of syllables, as used to compose his name, are no longer put together and founded amongst the living.

DONAUESCHINGEN, or **DONESCHINGEN**, a town of Suabia, in the principality of Furlenburg. It is the chief residence of the prince; in the court-yard of whose palace are some springs, collected in a reservoir about 30 feet square, from which issues a little brook; and though the rivulets Bribach and Brege, uniting below the town, are far more considerable than this stream, which flows into them soon after their junction, yet has this alone the honour of being called the head of the Danube.

DONCHERRY, a town of France, in the department of Ardennes, seated on the Meuse, three miles from Sedan. Long. 5. 2. E. Lat. 49. 42. N.

DONEGAL, a county of Ireland, in the province of Ulster, 68 miles long and 44 broad; bounded on the E. by Londonderry and Tyrone, on the W. and N. by the ocean, and on the S. by Fermanagh and the bay of Donegal. It contains 40 parishes, and lends 12 members to parliament. It is in general a champaign country, and abounds with harbours.

DONEGAL, a town of Ireland, capital of a county of the same name, seated on the bay of Donegal, 10 miles N. of Ballyshannon. Long. 7. 47. W. Lat. 54. 42. N.

DONERAILE, a town of Ireland, in the county of Cork. Near it are quarries of beautiful variegated marble. It is situate on the Awbeg, 19 miles N.W. of Cork, and 113 S.W. of Dublin. Long. 8. 42. W. Lat. 52. 5. N.

DONGALA, or **DONCALA**, a town of Nubia, with a castle. It contains 10,000 houses of wood, and is seated on the Nile, among mountains, 150 miles N. of Sennar. Long. 30. 35. E. Lat. 21. 0. N.

DONJON, a town of France, in the department of Allier, 24 miles S.E. of Moulins. Long. 3. 42. E. Lat. 46. 21. N.

DONZY, a town of France, in the department of Nièvre, 22 miles N. of Nevers. Long. 3. 14. E. Lat. 47. 22. N.

DOOAB, or **DOABAB**, a fertile tract of Hindoostan Proper; between the Ganges and Jumna, and formed by the confluence of those rivers. It is so named by way of eminence; the word signifying a tract of land formed by the approximation of two rivers. The principal part of it is subject to the nabob of Oude.

DOON, LOCH, a lake of Ayrshire, in the district of Kyle, six miles in length, and of considerable breadth. On an island in this lake stands Balloch Castle.

DOON, a river of Scotland, which issues from Loch Doon, and taking a N.W. direction, divides the district of Kyle from Carrick; the southern division of Ayrshire, and falls into the frith of Clyde.

DOOR-CLOSER, a machine or contrivance, calculated to be morticed into the bottom of a door, in order to keep the wind from coming in, and so that the door may yet pass freely over the carpet, &c. It is shewn in Plate 20, where, Fig. 1. represents the machine laid open to shew the work.

Fig. 2. the same represented as if the door were shut.

a. A spring, which, when the door is open, by compressing the inner ends of the rods, *bb*, turning on the centres, *cc*, cause the outer ends to rise along with the slip of wood, *d*, by which the door may pass over the carpet; *e* is the end of one rod, which, when shut against the friskening-plate, *f*, on the door-post, causes the slip of wood, *d*, to close on the door, and prevent any wind coming underneath the door.

DORAN, a town of Arabia, in Yemen, 28 miles S. of Sanaa. Long. 44. 4. E. Lat. 14. 55. N.

DORAT, a town of France, in the department of Upper

Vienne, seated on the Abran, near its junction with the Sevre, 25 miles N. of Limoges. Long. 1. 24. E. Lat. 46. 12. N.

DORCHESTER, a town in Oxfordshire, which was a station of the Romans, and ruined in the wars with the Danes. It was a bishop's see, till 1086, when William the Conqueror translated it to Lincoln; and it had five stately churches, though now but one. It gives the title of baron to the family of Carleton, and is seated on the Tame, 10 miles S.E. of Oxford, and 49 W.N.W. of London. Long. 1. 0. W. Lat. 51. 39. N.

DORDOGNE, a department of France, which includes the late province of Perigord. It receives its name from a river, which rises in the mountains of Auvergne, and falls into the Garonne, near Bourdeaux.

DORN, a village in a detached part of Worcesterhire, three miles S.E. of Camden in Gloucestershire. The Roman highway runs through it. There are evident tokens of its antiquity, and of its having been a Roman colony; abundance of coins, both Roman and British, having been found here.

DORNBURG, a town of Upper Saxony, in the principality of Weimar, 14 miles E. of Weimar.

DORNOCH, the county-town of Sutherlandshire, at the entrance of a frith of the same name, over which it has a ferry to Tain. It is a small place, and half in ruins, but was the residence of the bishops of Caithness. Part of the cathedral serves for the parish church; the other part is in ruins. It is 40 miles N.E. of Inverness. Long. 3. 48. W. Lat. 57. 52. N.

DORPT, or DORPAT, a town of Livonia, on the Embere, between the lakes Woiero and Pepas, 60 miles S. of Narva. Long. 27. 52. E. Lat. 58. 18. N.

DORSTEN, a town of Germany, in the circle of Lower Rhine. Though strong, it was several times taken and retaken by the Swedes and Hessians during the long war of Germany. It is seated on the Lippe, 30 miles N. of Dusseldorf, and 31 S.W. of Munster. Long. 6. 50. E. Lat. 51. 42. N.

DOUBLE-EMPLOYMENT (*Encycl.*). With respect to what M. D'Alembert adds in his Elements of Music, p. 80, and which he repeats in the Encyclopédie, article DOUBLE-EMPLA, viz. that the chord of the seventh *re fa la ut*, though we should even regard it only as an inversion of *fa la ut re*, cannot be followed by the chord *ut mi sol ut*; "I cannot (says Rousseau) be of his opinion in this point.

"The proof which he gives for it is, that the dissonance *ut* of the first chord cannot be resolved in the second; and this is true, since it remains in its place: but in this chord of the seventh *re fa la ut*, inverted from this chord of the superadded sixth *fa la ut re*, it is not the *ut*, but the *re*, which is the dissonance; which, of consequence, ought to be resolved in ascending upon *mi*, as it really does in the subsequent chord; so that this procedure in the bass itself is forced, which, from *re*, cannot without an error return to *ut*, but ought to ascend to *mi*, in order to resolve the dissonance.

"M. D'Alembert afterwards shews, that this chord *re fa la ut*, when preceded and followed by that of the tonic, cannot be authorized by the double-employment: and this is likewise very true; because this chord, though figured with a 7, is not treated as a chord of the seventh, neither when we make our entrance to it, nor our exit from it; or at least that it is not necessary to treat it as such, but simply as an inversion of the superadded sixth, of which the dissonance is the bass: in which case we ought by no means to forget, that this dissonance is never prepared. Thus, though in such a transition the double-employment is not in question, though the chord of the seventh be no more than apparent, and impossible to be resolved by the rules, this does not hinder the transition from being proper and regular, as I have just proved to theorists, Vol. X.

and as I shall immediately prove to practical artists, by an instance of this transition; which certainly will not be condemned by any one of them, nor justified by any other fundamental bass except my own. (See the Musical Dictionary, Plate D, fig. 14.)

"I acknowledge, that this inversion of the chord of the sixth superadded, which transfers the dissonance to the bass, has been censured by M. Rameau. This author, taking for a fundamental chord the chord of the seventh, which results from it, rather chose to make the fundamental bass descend diatonically, and resolve one seventh by another, than to unfold this seventh by an inversion. I had dissipated this error, and many others, in some papers which long ago had passed into the hands of M. D'Alembert, when he was composing his Elements of Music; so that it is not his sentiment which I attack, but my own opinion which I defend."

For what remains, the double-employment cannot be used with too much reserve, and the greatest masters are the most temperate in putting it in practice.

DOUBLET (*Encycl.*). The manner of making doublets is as follows:

Let the crystal or glass be first cut by the lapidaries in the manner of a brilliant, except that, in this case, the figure must be composed from two separate stones, or parts of stones, formed in the manner of the upper and under parts of a brilliant, if it was divided in an horizontal direction, a little lower than the middle. After the two plates of the intended stone are thus cut, and fitted so exactly that no division can appear when they are laid together, the upper part must be polished ready for setting; and then the colour must be put betwixt the two plates by this method. "Take of Venice or Cyprus turpentine two scruples; and add to it one scruple of the grains of mastich chosen perfectly pure, free from foulness, and previously powdered. Melt them together in a small silver or brass spoon ladle, or other vessel, and put to them gradually any of the coloured substances below mentioned, being first well powdered; stirring them together as the colour is put in, that they may be thoroughly commixed. Warm then the doublets to the same degree of heat as the melted mixture; and paint the upper surface of the lower part, and put the upper one instantly upon it, pressing them to each other, but taking care that they may be conjoined in the most perfectly even manner. When the cement or paint is quite cold and set, the redundant part of it, which has been pressed out of the joint of the two pieces, should be gently scraped off the side, till there be no appearance of any colour on the outside of the doublets: and they should then be skillfully set; observing to carry the mounting over the joint, that the upper piece may be well secured from separating from the under one."

The colour of the ruby may be best imitated, by mixing a fourth part of carmine with some of the finest crimson lake that can be procured.

The sapphire may be counterfeited by very bright Prussian blue, mixed with a little of the above-mentioned crimson lake, to give it a cast of the purple. The Prussian blue should not be very deep-coloured, or but little of it should be used: for otherwise, it will give a black shade that will be injurious to the lustre of the doublets.

The emerald may be well counterfeited by distilled verdigrease, with a little powdered aloes. But the mixture should not be strongly heated, nor kept long over the fire after the verdigrease is added: for the colour is to be soon impaired by it.

The resemblance of the garnet may be made by dragon's blood; which, if it cannot be procured of sufficient brightness, may be helped by a very small quantity of carmine.

The amethyst may be imitated by the mixture of some
7 M.

Prussian-blue with the crimson lake; but the proportions can only be regulated by directions, as different parcels of the lake and Prussian blue vary extremely in the degree of strength of the colour.

The yellow topazes may be counterfeited by mixing powdered ashes with a little dragon's blood, or by good Spanish anotto: but the colour must be very sparingly used, or the tinge will be too strong for the appearance of that stone.

The chrysolite, hyacinth, vinegar garnet, eagle marine, and other such weaker or more diluted colours, may be formed in the same manner, by lessening the proportions of the colours, or by compounding them together correspondently to the hue of the stone to be imitated; to which end it is proper to have an original stone, or an exact imitation of one, at hand when the mixture is made, in order to the more certain adapting the colours to the effect desired: and when these precautions are taken, and the operation well conducted, it is practicable to bring the doublets to so near a resemblance of the true stones, that even the best judges cannot distinguish them, when well set, without a peculiar manner of inspection.

DOUBS, a department of France, including part of the late province of Franche Comté. It is so named from a river which falls into the Rhone.

DOUE, a small town of France, in the department of Maine and Loire. It has one of the finest fountains in France; and near it is a vast Roman amphitheatre, cut out of the solid rock. It had, in the time of the monarchy, a considerable manufacture of druggets and tammies. It is nine miles S.W. of Saumur.

DOVE, a river in Derbyshire, which rises in the Peak, parts the county from Staffordshire, and falls into the Trent, four miles N. of Burton.

DOVEDALE, one of the most romantic spots in Derbyshire, in the neighbourhood of Ashborn. Here the river Dove runs in a chasm between precipitous rocks.

DOUERO, or DOURO, a river of Spain, which rises in Old Castile, in the mountains of Urbion, runs W. by several towns, and crossing Portugal, falls into the Atlantic Ocean, near Oporto.

DOUGLAS, CAPE, a lofty promontory, on the W. coast of America, within the entrance of Cook's Inlet. Its summit appears above the clouds, forming two very high mountains. Long. 153. 30. W. Lat. 58. 56. N.

DOUGLAS (Gavin), bishop of Dunkeld in Scotland, was the third son of Archibald earl of Angus, and born in the year 1474. Where he was educated, is not known; but it is certain that he studied theology: a study, however, which did not estrange him from the muses; for he employed himself at intervals in translating into beautiful verse the poem of Ovid *de Remedio Amoris*. The advantages of foreign travel, and the conversation of the most learned men in France and Germany, to whom his merit procured the readiest access, completed his education. With his superior recommendations and worth, it was impossible he could remain unnoticed. His first preferment was to be provost of the collegiate church of St. Giles in Edinburgh; a place, at that time, of great dignity and revenue. In the year 1514, the queen mother, then regent of Scotland, appointed Douglas, abbot of Aberbrothock, and soon after archbishop of St. Andrew's; but, the queen's power not being sufficient to establish him in the possession of that dignity, he relinquished his claim in favour of his competitor Foreman, who was supported by the pope. In 1515 he was by the queen appointed bishop of Dunkeld; and that appointment was soon after confirmed by his holiness Leo X. Nevertheless it was some time before he could obtain peaceable possession of his see. The duke of Albany, who in this year was declared regent, opposed him because he was sup-

ported by the queen; and, in order to deprive him of his bishopric, accused him of acting contrary to law in receiving bulls from Rome. On this accusation he was committed to the castle of Edinburgh, where he continued in confinement about a year; but the regent and the queen being at last reconciled, he obtained his liberty, and was consecrated bishop of Dunkeld. In 1517 he attended the duke of Albany to France; but returned soon after to Scotland. In 1521, the disputes between the earls of Arran and Angus having thrown the kingdom into violent commotion, our prelate retired to England, where he became intimately acquainted with Polydore Virgil the historian. He died in London, of the plague, in 1522; and was buried in the Savoy.

He wrote, 1. The Palace of Honour: a most ingenious poem under the similitude of a vision; in which he paints the vanity and inconsistency of all worldly glory. It abounds with incidents, and a very rich vein of poetry. The palace of happiness, in the picture of Cebes, seems to be the ground-work of it.—2. Aureæ Narrationes: a performance now lost; in which, it is said, he explained, in a most agreeable manner, the mythology of the poetical fictions of the ancients.—3d. Comedie aliquot Sacre: none of which are now to be found. 4. Thirteen Books of Eneades, of the famous Poet Virgil, translated out of Latin verses into Scottish metre, every buke having its particular prologue. Imprinted at Lond. 1553, in 4to.; and reprinted at Edinburgh 1710, in folio.—The last is the most esteemed of all his works. He undertook it at the desire of Lord Henry Sinclair, a magnificent patron of arts in those times; and he completed it in 18 months; a circumstance which his admirers are too fond of repeating to his advantage. David Hume of Godscroft, an author of uncommon merit, and an admirable judge of poetry, gives the following testimony in his favour: "He wrote (says he), in his native tongue, divers things; but his chiefest work is his translation of Virgil, yet extant, in verse: in which he ties himself so strictly as is possible; and yet it is so well expressed, that whosoever will essay to do the like, will find it a hard piece of work to go through with it. In his prologues, before every book where he hath his liberty, he sheweth a natural and ample vein of poetry, so pure, pleasant, and judicious, that I believe there is none that hath written before or since, but cometh short of him."

It has been said, that he compiled an historical treatise *De Rebus Scoticis*; but no remain of it hath descended to the present times.

DOULAINCOURT, a town of France, in the department of Upper Marne, 10 miles S.W. of Joinville.

DOURAK, a town of Persia, near the confluence of the Euphrates and Tigris, remarkable for the reed of which they make pens. Long. 56. 57. E. Lat. 32. 15. N.

DOURDAN, a Town of France, in the department of Seine and Oise, with a manufacture of silk and worsted stocking. It is seated on the Orge, 25 miles S. W. of Paris. Long. 2. 10. E. Lat. 48. 35. N.

DOURLACH, a town of Suabia, capital of Baden Dourlach. It was burnt by the French in 1680. The inhabitants are Protestants. It is seated on the Gießen, 12 miles S. of Philippsburg. Long 9. 28. E. Lat. 49. 2. N.

DOURENS, or DOULENS, a town of France, in the department of Somme, with two citadels. It is seated on the Autie, 15 miles N. of Amiens. Long. 2. 25. E. Lat. 50. 10. N.

DOUSA (Janus), a very learned man, was born of a noble family at Nortwick in Holland, in 1545. He lost his parents when very young, and was sent to several schools; to one at Paris, among the rest, where he made a great progress in Greek and Latin learning. When he had finished his educa-

tion, he returned to his own country, and married; and though he was scarcely grown up, he applied himself to affairs of state, and was soon made a curator of the banks and ditches, which post he held above twenty years, and then resigned it.

Doufa was not only a scholar and a statesman, but likewise a soldier; and he behaved himself so well in that capacity at the siege of Leyden 1574, that the Prince of Orange thought he could commit the government of the town to none so properly as to him. In 1575 the university was founded there, and Doufa made first curator of it; which place he was very fit for, as well on account of his learning, as for his other defects. His learning was indeed prodigious; and he had such a memory, that he could at once give an answer to any thing that was asked him, relating to ancient or modern history, or, in short, to any branch of literature. He was, says Melchior Adam, and Thuanus says the same, a kind of living library; the Varro of Holland, and the oracle of the university of Leyden. His genius lay principally towards poetry, and his various productions in that way were numerous; and what seems remarkable enough, he composed the annals of his own country, which he had collected from the public archives, in verse. He wrote also a great many things in the critical way; as, notes upon Horace, Sallust, Plautus, Petronius, Catullus, Tibullus, &c. His moral qualities are said to have been no less meritorious, than his intellectual and literary; for he was modest, humane, benevolent, and open. He was admitted into the supreme assembly of the nation, where he kept his seat, and discharged his office worthily, for the last thirteen years of his life. He died in 1604, and his funeral oration was made by Daniel Heinfius.

He left four sons behind him; the eldest of which, Janus Doufa, had he lived, have been a more extraordinary man than his father. Joseph Scaliger called him the ornament of the world; and says, that in the flower of his age he had reached the same maturity of wisdom and erudition, as others might expect to reach after a life spent in study. Grotius also assures us, that his poems exceeded those of his father; and that he assisted his father in composing the Annals of Holland. He was born in 1572; and before he was well out of infancy, became, through the great care of his father, not only a good linguist and poet, but also a good philosopher and mathematician. To all this he afterwards added an exquisite knowledge of the civil law and of history. Besides a great many poems, which he composed in a very tender age, we have notes and observations which he made upon several Latin poets. Those upon Plautus were the produce of his 16th year; and he was not above 19 when he published his book *De Rebus Cœlestibus*, and his Panegyric upon a Shadow. His commentaries upon Catullus, Tibullus, and Propertius, were published the same year. His extraordinary fame and merit caused him to be made preceptor to the Prince of Orange, and afterwards first librarian of the university of Leyden. He died at the Hague, in his return from Germany; very immaturely, for his death happened in 1597, when he had not quite completed his 26th year.

Doufa's three other sons, George, Francis, and Theodorus, were all of them men of learning, though not so much above the common rate as Janus was. George was a good linguist; travelled to Constantinople; and published a relation of his journey, with several inscriptions which he found there and elsewhere. Also, in 1607, he printed George Codrenus's book, entitled, *De Originibus urbis Constantinopolitaneæ*, with Meursius's notes upon it. Francis was far from wanting learning; for, in 1600, he published the epistles of Julius Cæsar Scaliger; his annotations upon Aristotle's History of Animals; and some fragments of Lucilius, with notes of his own upon them. Theodorus, lord of Barkeniten, published

the Chronicon of George Logotheta with notes, in 1614; and, in 1638, wrote a treatise, called *Farrago Ethica variarum Linguarum, variorumque auctorum*, &c.

DOWLATABAD, formerly called Amednagar, a province of the Deccan of Hindoostan. It is bounded on the N. by Candeleth and Malway, on the W. by the Gauts, on the S. by Visapur and Golconda, and on the E. by Berar. Auringabad is the capital.

DOWLATABAD, a fortress in the Deccan of Hindoostan, 15 miles N.W. of Auringabad. In the neighbourhood are the pagodas of Elora, most of which are cut out of the natural rock. Long. 76. o. E. Lat. 19. 55. N.

DRABICIUS (Nicholas), a celebrated enthusiast, was born about 1587, at Stranitz in Moravia, where his father was burgomaster. He was admitted minister in 1616, and exercised his function at Drakotutz; and, when he was obliged to seek a retreat in foreign countries, on account of the severe edicts of the emperor against the Protestant religion, he retired to Leidnitz, a town in Hungary, in 1629. Having no hopes of being restored to his church, he turned woollen-draper; in which occupation his wife, who was the daughter of one, was of great service to him. Afterwards he forgot the decorum of his former character so much that he became a hard drinker; but the other ministers, justly displeased at his conduct, informed their superiors of it, who, in a synod which was called in Poland, examined into the affair. Here it was resolved, that Drabicius should be suspended from the ministry, if he did not live in a more edifying manner; and this obliged him to behave himself with more decency.

When he was upwards of 50 years of age, he commenced prophet. He had his first vision in the night of Feb. 23, 1638, and the second in the night of Jan. 23, 1643. The first vision promised him in general great armies from the North and East, which should crush the house of Austria; the second declared particularly, that Ragotki, prince of Transylvania, should command the army from the East, and ordered Drabicius to inform his brethren, that God was about to restore them to their own country, and to revenge the injuries done to his people; and that they should prepare themselves for this deliverance by fasting and prayer. He received orders to write down what had been revealed to him; and to begin in the manner of the ancient prophets, "The words of the Lord came unto me." His visions, however, were not paid much regard to at first. These two were followed by many others in the same year 1643; and there was one, which ordered, that he should open the whole affair to Comenius, who was then at Elbing in Prussia. One of his visions in 1644 assured him, that the imperial troops should not destroy the refugees. They committed great ravages upon the territories of Ragotki, plundered the town of Leidnitz, and besieged the castle. Drabicius shut himself up there, and did not depend so entirely upon the Divine assurances, as to think human means unnecessary. He even set his hand to the work: and fired one of the cannon himself. The Imperialists raised the siege; but soon after, besieged the place again, and took it. The refugees were plundered, and Drabicius fell into the hands of the Imperialists. This did not prevent him from going to Ragotki, and telling him, Aug. 1645, that God commanded him to destroy the house of Austria and the pope; and that, "if he refused to attack that nest of vipers, he would draw down upon his family a general ruin, which should not spare even him that pisteth against the wall." The prince already knew, that Drabicius had assumed the character of a prophet: for Drabicius, according to the repeated orders which he had received in his extasies, had sent him a copy of his revelations, which Ragotki threw into the fire. The death of that prince, in Oct. 1647, plunged Drabicius into extreme sorrow; who

was in the utmost fear, left his revelation should vanish into smoke, and himself be exposed to ridicule. But he had one extatic consolation, which re-animated him; and that was, that God would send him Comenius, to whom he should communicate his writings. Comenius, having business in Hungary in 1650, saw Drabicius there, and his prophecies; and made such reflections as he thought proper, upon the vision's having for three years before promised Drabicius, that he should have Comenius for a coadjutor. Must it not seem strange, that Sigismund Ragotzki, being urged by Drabicius to make war against the emperor, and by his mother to continue in peace with him, could not tell what to do, being attacked on both sides with terrible threats? Drabicius denounced against him the judgments of the Almighty, in case of peace; and his mother threatened him with her curse, in case of war. Should not the prince have followed where reason and good policy would have led, and have left these mad people to have raved as long as they pleased, each in their own way? He fat down however in the utmost perplexity, recommended himself to the prayers of Drabicius and Comenius, and kept himself quiet till his death.

June 1654, Drabicius was restored to his ministry, and his visions presented themselves more frequently than ever; ordering from time to time, that they should be communicated to his coadjutor Comenius, that he might publish them to all nations and languages, and particularly to the Turks and Tartars. Comenius found himself embarrassed between the fear of God, and that of men: he was apprehensive, that by not printing the revelations of Drabicius he should disobey God, and that by printing them he should expose himself to the ridicule and censure of men. He took a middle way: he resolved to print them, and not to distribute the copies; and upon this account, he entitled the book, *Lux in Tenebris*. But his resolution to conceal this light under a bushel did not continue long: it gave way to two remarkable events, which were taken for a grand crisis, and the unravelling of the mystery. One of these events was the irruption of George Ragotzki into Poland: the other, the death of the emperor Ferdinand III. But these events, far from answering the predictions, served only to confound them. Ragotzki perished in his descent upon Poland; and Leopold king of Hungary was elected emperor in the room of his father Ferdinand III. by which election, the house of Austria was almost restored to its former grandeur, and the Protestants in Hungary absolutely ruined. Drabicius was the greatest sufferer by this; for the court of Vienna, being informed that he was the person who founded the trumpet against the house of Austria, sought means to punish him, and, as it is said, succeeded in it. What became of him, we cannot learn: some say, that he was burnt for an impostor and false prophet; others, that he died in Turkey, whither he had fled for refuge: but neither of these accounts is certain.

The *Lux in Tenebris* was printed by Comenius at Amsterdam in 1657; and contains not only the revelations of our Drabicius, but those also of Christopher Kotterus, and of Christina Poniatovia. Comenius published an abridgment of it in 1660, with this title, *Revelationum divinarum in Usum Sæculi nostri factarum Epitome*: that is, An Epitome of the divine Revelations communicated for the Use of this our Age. He reprinted the whole work, with this title, *Lux e Tenebris novis Radiis aucta*, &c. These new rays were a sequel of Drabicius's revelations, which extended to the year 1666.

DRACHENFELS, a town of Germany, in the electorate of Cologne, with a citadel, seven miles N.W. of Lintz.

DRAG-CART, an invention of Lord Somerville, which

promises to be eminently useful to the farmers of this country. The following description of it and of the method of adjusting the centre of gravity of the load, is published in the Communications of the Honourable Board of Agriculture.

Fig. 1, in Plate 24, is a perspective-view of a cart, for a single horse, calculated to carry 35 cwt.; in the front of which is represented the method of adjusting the position of the centre of gravity of the load, to prevent its pressing too much on the cattle in going down hill, the front of the cart being elevated by means of a toothed rack screwed to the front of the cart, and worked by a pinion, and the handle *a* immediately connected with the shaft *e*. By means of this pinion and racks, the front of the carriage is elevated more or less, in proportion to the declivity of the hill, by which means the weight of the load is made to bear more on the axis, and less on the horse.

On the side-view of the cart is represented the manner of applying the *friction-drag*, which is made to press, more or less, on the side of the wheel, according to the steepness of the descent: *b b*, is the friction-bar, or drag; one end of which is connected with the tail of the cart by a small chain, and the other end to the front, by means of a toothed-rack *b d*, which catches on a staple in the front of the cart, by which the friction-bar may be made to press on the side of the wheel, more or less, at the discretion of the driver; the notches of teeth in this rack should be as close to each other as circumstances will permit.

The friction-bar is here applied lower upon the wheel than was at first purposed, in order to divide the pressure and friction more equally on the opposite side of the wheel, so that the pressure on each is diminished; the risk of over-heating and destroying the friction bars is also rendered less than if the whole pressure was applied in one point at the top of the wheel.

Fig. 2, in Plate 24, is a view of a drag-cart calculated to carry 25 cwt.

As the advantages of the friction-drag have been fully stated in Mr. Cumming's observations on wheel-carriages, it would be superfluous to repeat them here.

By an attentive comparison of carts drawn by shafts with those drawn by the yoke and bows, the superiority of the pole to the shafts *, and the advantage of making the cattle draw by the yoke, in preference to drawing by the forehead, become evident.

When cattle draw by the shafts (the one before the other), it is impossible for the driver to know that each exerts an equal force, so as to contribute equally to the draught; but when they draw by the pole and yoke, the point of draught being in the middle of the yoke, when the beast draws equally, the yoke will stand square with the pole, and the position of the yoke will always enable the driver to discover the default, and to bring it to a proper exertion: it is this harmony of draught, and equality of exertion, that gives so great an advantage to drawing by the yoke, that it is scarcely possible to say what weight of a lead too good large oxen can draw on a level road. The powers of cattle drawing by the forehead, on Lord Shannon's estate, are recorded by Mr. Young and Mr. Billingley: an ox of the late Mr. Tatterfall, near Ely, drew four ton of wood on a level surface without apparent difficulty. What then might not be expected from the equal exertions of two such powerful animals, acting at the equal ends of the same yoke!

WHEEL-DRAW, an implement of iron, which, being chained to the wheel of a cart or waggon, supports it while the horses stop upon a hill. See CART, *Supp.* and PL. 19.

* The apparatus for adjusting the centre of gravity of the load may in such case be fixed to the pole of the cart, in the same manner as above described to be fixed on the shaft.

Drag Cart.

M. Andrews's Weighing-Crane.

DRAGOMESTRO, a town of European Turkey, in Li-vadia, taken by the Venetians in 1684, but abandoned soon after. It is 44 miles W.N.W. of Lepanto.

DRAGUIGNAN, a town of France, in the department of Var, 10 miles N.W. of Frejus. Long. 6. 35. E. Lat. 43. 31. N.

DRAIN (*Encycl.*). The following sketch of the drainage and improvement of a marsh, near Marazion in Cornwall, describing a peculiar mode of taking off the water, and securing the land from the overflowing of the sea, by Mr. Richard Moyle, of Marazion, is taken from the Communications to the Board of Agriculture.

A piece of land called the marsh, or bog, near Marazion in Cornwall, containing thirty-six statute acres, has, from time immemorial, been covered with two or three feet of water, and which, at spring-tides, was overflowed with the sea, by means of a river which passed through the land. This ground looks towards the south, and is separated from the sea by a long skirting of sand of about seventeen acres; over which the turnpike road passes towards Penzance, on its most elevated part: on the north of the marsh lies some croft ground (i. e. higher and not subject to inundations), which gradually rises as it retires from the bog, so that the marsh is surrounded on the north and south by elevated spots; and the water on its surface usually crept away to the sea by means of a river, through which the water at high spring-tides always had access. From the depressed situation of this marsh, it was impossible to take off all the surface water through the river, and recourse was had, for this purpose, to a square wooden pipe of nine inches diameter, which was introduced at that part of the shore called half-ebb, and which was eight feet lower than the surface of the marsh. This pipe was introduced through the sandy soil, in some places twenty-four feet deep, till it arrived at the fourth part of the bog, where it was found to be six feet under the surface. At this place a reservoir of eighteen feet square, and eight feet deep, was immediately cut out; and the water draining from the marsh, during the time the tide was in, was received in the reservoir, and discharged when the tide was out, through the pipe with great velocity. The sea, at high water, covers this pipe with nine or ten feet of water: a long trench, of three feet deep and five wide, was extended from this place, east and west, on the fourth side of the bog, for its whole length, bordering on the sandy soil; and at the distance of every sixty yards, a similar trench was cut up directly north towards the croft, which divided the whole marsh into oblong square fields. By the means of these trenches, or open drains, the whole surface water was conveyed directly to the reservoir, and thence to the sea. The pipe at both its extremities was guarded with valves, which shut at the approach of the tide; and during its flowing, the water accumulated about two, or two and a half feet high in the reservoir; and as the sea retires, the collected water runs off without any interruption, till the next return of the tide: the pipe is covered with the sea six hours in every twelve. This singular mode of drainage answers uncommonly well, and has never once failed in five years: the extremities of the pipe have also iron bars placed before them, to prevent the intrusion of extraneous bodies. As soon as the surface water was removed, a strong embankment of turf was made on the south and east sides, to prevent the overflowing of the tides; and the water, which formerly diffused itself over the whole of this ground, was collected into a river, and carried to the sea on the outside of this embankment. In cutting the open drains, a pot of copper coins, containing about a thousand, was discovered three feet under the surface, and which appeared to belong to the Emperor Victorinus, who reigned in the third century. These coins were much injured

by the corrosion of the salt water; but several were still perfect enough to trace the outlines of the Emperor. As soon as the evaporation had assisted the consolidation of the surface, the air, within a mile of the marsh, became so strongly impregnated with a sulphureous smell, as to render the place quite obnoxious to passengers.

On examining the different strata, we found that two feet and a half of the surface consisted of mud and a peaty substance, most strongly interwoven with the roots of goss (*Arundo phragmites*) and common rushes, which were the only substance that grew spontaneously on its surface; below this, was a stratum of three feet and a half of pure peat, of a very inflammable nature, and which seems to have extended over twenty acres of the marsh; under the peat lay a bed of sand, from four to six feet deep; from which we may conjecture that the whole was formerly an arm of the sea, and that the dropping of vegetables, and deposition of mud (which possibly formed the peat), had gradually expelled the sea; except at spring-tides. This stratum of sand does not appear to be the original bed of the sea; for, on streaming for tin, another floor from six to ten feet deeper was discovered, consisting of round smooth pebbles, and gravelly substances, containing tin; among which were willow trees and hazel nuts, in the most perfect state.

The mode of improvement adopted was the following:—The surface was pared and burned; and after repeated ploughings, &c. for two years, large bodies of clay, with manure, were then, carried on its surface, and a slight crop of white oats with ever-grass (ray), common and Dutch clover, sown in the spring. The saltness of this ground was so very powerful for the first three years, as to destroy every crop; on the fourth, the land began to vegetate partially; but on the fifth, or present year, 1798, every part seems to be quite alive; so that every kind of vegetable now flourishes with great luxuriance. It has afforded this summer very good crops of hay, and an abundant and rich pasture, with a prospect of improvement the next season. The expenses of draining this ground, with trenching, paring, ploughing, burning, and manuring it, with the failure of three years' crops, amount to a very considerable sum; and this distressing circumstance is increased, on its being only a leasehold for three lives.

The sandy land has been partly inclosed, and covered with large bodies of clay and manure; it has afforded remarkably fine crops of turnips, and the grass of this season has been very luxuriant. The crofty land on the north (twenty-two acres) has been all cultivated, first with potatoes, and afterwards sown with wheat, barley, oats, and turnips, and produced very good crops.

The whole of this improved ground has been productive of considerable advantages to the public, particularly to the poor. Four hundred persons yearly receive turf from it; two hundred and fifty are fed most plentifully with potatoes, which are planted here by very poor people, who are, in consequence of having land given them, become uncommonly industrious; and the whole neighbourhood, by its drainage, have got rid of low nervous fevers and agues, with which it was continually pestered.

The whole ground under improvement consists of seventy-five acres, of which thirty-six are marsh, twenty-two croft, and seventeen of sand. In 1798, forty acres were under different crops; viz. wheat two acres and a half, barley nine, oats eight, turnips two, potatoes five, hay and pasture thirteen and a half.

On the sides of every open trench is planted a row of quicksets, interspersed with a few planes and pineastres. These are defended from the cattle and blights by means of a temporary turf hedge, and promise to afford a pleasing division of the land

in a few years. To every inclosure of the marsh a part of the rising ground of the croft is annexed to accommodate cattle in wet seasons.

In the year 1798 this land was visited and examined on the spot as to the facts, by Sir John Call, and the above particulars given him by the proprietor.

We shall conclude this article with an account of the effect of a luxuriant weed, called by botanists the *Equisetum Palustre*, upon drains. Sir Joseph Banks, in a letter to the Secretary of the Board of Agriculture, communicates the following particulars:

"Few objects of agricultural utility, says the Baronet," "have ever interested me so much, and I have no hesitation in saying that none are, in my opinion, so interesting to the increasing prosperity of the landed interest of this kingdom, as the theory of draining whole districts, by tapping the mother springs that overflow their surface, and conducting drains through the principal valleys, so contrived as not only to render the boggy parts of them found land, but also to free the sides of the hills which form them, from all out-bursts of water.

"Mr. Ellington is certainly the father of this system of drainage, but Mr. Farey has perfectly comprehended all the works done by that gentleman, for the Duke of Bedford, and in the mode of conducting the operations now carrying on, has, in some instances, excelled them, founding his practice on an extensive and enlightened theory, applicable to all valley bogs, in the drainage of which, it appears to me almost impossible that his method should fail, under any circumstances.

"One thing, however, has occurred, in the short experience of the Woburn operations (about five years), which appears to me of consequence enough to warrant the trouble this will give to you and the Board. Some bogs, drained by under drains made at a great expence through the moist mry parts of them, appeared at first perfectly dry, but have since been found to grow by degrees less and less so. On examination, these drains have been found more or less choked up by a plant vegetating within them, and forming both stems and roots, the whole several yards in length, intercepting the course of the water, weakening the current by degrees, and at last wholly choking up the drain.

"This plant is the *equisetum palustre*, a weed common in moorish and swampy places, but hitherto little noticed by naturalists; its root, or rather its stem under ground, is a yard or more in length, and in size like packthread; from this, a root of twice the size of the stem runs horizontally in the ground, taking its origin from a lower root, which strikes downwards perpendicularly to a depth I have not hitherto been able to trace, as thick as a small finger; this perpendicular root forms in some places beds, which occupy a large portion of the more solid part of a peaty bog, as may be seen in some parts of the banks of the Duke's open drains.

"As the bud by which the plant appears to renew itself in spring, is situated on the horizontal root, a yard or more in depth, the shoot must, in its progress upwards, be liable to meet with under drains, and penetrate into them, through the openings left for the passage of the water. When once entered, nature, which has given to the plant the power of piercing the soil upwards from a great depth, enables it to live in the confined atmosphere of a drain, where, as it is continually drawn forward by the current, the joints lengthen themselves beyond their natural dimensions; hence it is probable that when drains choked with it, are taken up and carefully examined, the length of the plants will be found very much to exceed those I have observed."

The author hopes that this will lead to further discussion, and to the discovery of a remedy for this evil, which seems likely to put a stop to the practice of draining bogs, where

this mischievous plant grows, by under drains. It is necessary for the evil to be known, in order that those who possess bogs that have become mry after being drained, may be apprised of an evil, which can certainly be cured by the simple expedient of casting the under drains into open ones.

Common earth-drains are sometimes dug two or three spits deep, with a broad spade, the bottom is taken out with a narrow one, and filled with stones.—Sometimes a furrow is drawn with a plough, and cleared by a common spade: the draining instrument fig. 1, Plate 17, is then introduced to the depth of 18 inches from the surface; afterwards taking out the loose mold with the scoop fig. 2.

Hollow drains, without stones, have been tried on stiff lands: they are made narrow at the bottom, and covered half way up with fods, or square pieces of the surface-soil, resting on ledges cut for that purpose.

It is much to be lamented, that we possess, in this cold climate, no grain similar to *rice*, that would grow in watery grounds which cannot be drained, nor indeed any esculent roots or foliage, except water-cresses. In such situations, some plants may perhaps be cultivated with profit to the proprietor, as the *scilla maritima*, or floating fescue; *calitriche*, or star-grass, or star-wort; to which may be added the *orchis*, for the purpose of making salep, by drying the peeled roots in an oven. If these plants should not completely succeed, other vegetables of quick growth may be raised for manures, such as the *typha*, or cat's-tail; the *caltha*, or marsh-marigold, &c.; which should be mown twice a-year, while they are young, and abound with saccharine and mucilaginous matter, ready to pass into fermentation.

DRAKE (James), a celebrated political writer and physician, was born at Cambridge, in 1667; and, at 17, admitted a member of that university, where he soon distinguished himself by his uncommon parts and ingenuity. Some time before the Revolution, he took the degree of B. A. and after that of M. A. but, going to London, in 1693, and discovering a particular genius to the study of physic, he was encouraged in the pursuit of it by Sir Thomas Millington, and the most eminent members of the college of physicians. In 1696 he took the degree of doctor in that faculty; and was soon after elected F. R. S. as likewise of the college of physicians. But whether his own inclination led him, or whether he did it purely to supply the defects of a fortune, which was not sufficient to keep him a proper equipage as a physician in town, he applied himself to writing for the bookellers. In 1697 he was concerned in the publication of a pamphlet, entitled, *Compendary Verbes upon the Author of Prince Arthur and King Arthur*. In 1702 he published, in 8vo. *The History of the last Parliament*, begun at Westminster Feb. 20, in the 12th year of King William, A.D. 1700. This created him some trouble; for the House of Lords, thinking it reflected too severely on the memory of King William, summoned the author before them in May 1702, and ordered him to be prosecuted by the attorney-general; who brought him to a trial, at which he was acquitted the year following.

In 1704, being dissatisfied with the rejection of the bill to prevent occasional conformity, and with the disgrace of some of his friends who were fickle for it, he wrote, in concert with Mr. Poley, member of Parliament for Ipswich, *The Memorial of the Church of England*; humbly offered to the Consideration of all true Lovers of our Church and Constitution, 8vo. The treasurer, Godolphin, and the other great officers of the crown in the Whig interest, being therein feverely reflected on, were so highly offended at the publication of it, that they represented it to the queen as an insult upon her honour, and intimation that the church was in danger under her administration. Accordingly her Majesty took ho-

fice of it in her speech to the ensuing parliament, Oct. 27, 1705; and was addressed by both houses upon that occasion. Soon after, the queen, at the petition of the House of Commons, put out a proclamation for discovering the author of the Memorial; but no discovery could be made. The parliament was not the only body that shewed their resentment to this book; for the grand jury of the city of London having presented it at the sessions, as a false, scandalous, and traitorous libel, it was forthwith burnt in the sight of the court then sitting, and afterwards before the Royal Exchange, by the hands of the common hangman. But though Drake then escaped, yet as he was very much suspected of being the author of that book, and had rendered himself obnoxious upon other accounts to persons then in power, occasions were sought to ruin him if possible; and a newspaper he was publishing at that time under the title of *Mercurius Politicus*, afforded his enemies the pretence they wanted. For, taking exception at some passages therein, they prosecuted him in the Queen's Bench in 1706. His case was argued at the bar of that court April 30; when, upon a flaw in the information, the trial was adjourned, and in November following the doctor was acquitted; but the government brought a writ of error. The severity of this prosecution, joined to repeated disappointments and ill usage from some of his party, is supposed to have flung him into a fever, of which he died at Westminster, March 2, 1706-7, not without violent exclamations against the rigour of his prosecutors. The Memorial was reprinted in 8vo. in 1711, with an introductory preface containing the author's life and death.

Besides the performances already mentioned, he made an English translation of Herodotus, which was never published. He wrote a comedy, called, *The Sham-Lawyer*, or the *Lucky Extravagant*; which was acted at the Theatre-Royal in 1697. It is chiefly borrowed from two of Fletcher's plays, namely, *The Spanish Curate*, and *Wit without Money*. He was the editor of *Historia Anglo-Scotica*; or, an impartial History of all that happened between the Kings and Kingdoms of England and Scotland, from the Beginning of the Reign of William the Conqueror to the Reign of Queen Elizabeth, 1703, 8vo. But whatever merit there might be in his political-writings, or however they might distinguish him in his life-time, he is chiefly known now by his medical works: by that *New System of Anatomy* particularly, which was finished a little before his decease, and published in 1707, with a preface by W. Wagstaffe, M. D. and reader of anatomy at Surgeons-Hall.

Drake (Francis), a surgeon at York, and an eminent antiquary, was much esteemed by Dr. Mead, Mr. Folkes, the two Mr. Gales, and all the principal members of the Royal and Antiquarian Societies. He published, in 1736, *Eboracum*; or, the History and Antiquities of the City of York, from its Original to the present Time; together with the History of the Cathedral Church, and the Lives of the Archbishops of that See, &c. By Francis Drake of the City of York, Gent. F. R. S. and Member of the Society of Antiquaries in London; a copy of which, with large MS. additions by the author, is in the hands of his son, the Rev. William Drake, F. A. S. late master of the free-school at Felsted in Essex, and, in 1783, vicar of Illeworth, Middlesex, who has distinguished himself by several curious articles in the *Archæologia*, IV. 143, V. 137, 139, and would republish his father's book if the plates could be recovered. A metzotinto print of Mr. Drake, by Val. Green, was published in 1771, from a picture by N. Drake, with this inscription: Franc. Drake, Armiger, Eboracensis, Reg. Soc. neonon Antiqu. Socius.

Drake (Samuel), was fellow of St. John's College, Cambridge, and contemporary with the above Dr. Drake, who published in 1729, in folio, a fine edition of Archbishop Parker's work, *De Antiquitate Britannicæ Ecclesiæ, & Privilegiis Ecclesiæ Cantuariensis, cum Archiepiscopis ejusdem LXX.* The archbishop's own edition, published by himself in 1572, was exactly followed, which contained not only the lives of the archbishops, but also a catalogue of the chancellors, vice-chancellors, proctors, and commencers in the university of Cambridge, from the year 1500 to 1571, with many other matters relating to that university. The copies of the archbishop's edition almost all varying from one another, the correctest was made the text, and the variations of the rest were taken notice of. Copper-plates were taken, by the best hand, of all the arms, frontispieces, and other decorations, in the edition of 1572.

DRAMA (*Encycl.*). To what has been already offered under this head, we purpose to add a brief history of the German Drama.

The German theatre continued a long time an object of little curiosity to other nations. It was about the year 1760 that the Arminius of Schlegel was translated into the French language; and about the same period the Death of Adam, by Klopstock, also appeared in the same tongue. In the year 1769 was published at Amsterdam, a volume, entitled, *Théâtre Allemand, ou Recueil de diverses Pièces traduites de l'Allemand, en Prose et en Vers, avec des Remarques: par C. D.* This volume comprises the Cato of Gottsched; the False Devotee, an excellent comedy by Gellert; and the Sick Woman, an interlude, by the same. The translator has prefixed some curious introductory matter, concerning the history of the German stage, to which the following remarks are greatly indebted.

The history of the German theatre may be divided into four periods.

PERIOD I.

Germany, like the other countries of Christendom, had its mysteries, or religious plays. The knights of the Teutonic order had recourse sometimes to dramatic exhibitions, in order to explain the mysteries of the faith to the rude understandings of the inhabitants of Courland and Livonia. It is not a little remarkable that Hrosvitha, a German nun, about the year 950, composed not only religious dramas, but some plays in imitation of Terence. They were printed at Nuremberg, A.D. 1500, in a very scarce folio volume, ornamented with wooden plates. Whether this attempt excited any imitators, must be left to the investigation of German antiquaries.

PERIOD II.

In the sixteenth century, the religious plays gave way to a kind of moral farces. Hans Sachsén is the earliest German dramatist, in his native language, whose name merits record. He was a shoemaker of Nuremberg, and has rivalled the famous Lopez de Vega, in the astonishing multitude of his dramatic performances.

PERIOD III.

A company of Dutch comedians passing into Germany, about the year 1620, operated the first reform in the German theatre. The Dutch had, at that time, made considerable progress in the dramatic art, and their theatre was on a respectable footing. They taught the Germans greater regularity and skill in the construction of the drama. Yet the Dutch tragedy was then very atrocious and sanguinary, and was intermingled with gross buffoonery; and their comedy was little better than an unnatural farce. In the latter department, Veis was one of the most celebrated writers of Germany.

Nevertheless, the Germans to this day boast of John Opitz, Andrew Gryphius, and Gasper de Lohenstein. Riccoboni, in his *Recherches sur les différents Théâtres de l'Europe*, has given a list of their pieces, which may be consulted by the curious reader. Opitz is regarded as a father of German poetry: he wrote a didactic treatise on the drama; and composed lyric poems and operas. National vanity has compared Gryphius to Shakpeare; and with more justice to Corneille, whom he somewhat resembles in the pomp of his verse, the depth of his thought, and the abundance of maxims and political discourse. To Shakpeare he can only be compared on account of the inequality of his scene. When Lohenstein is paralleled with Seneca, we sufficiently discover that he is only the skeleton of a dramatic author.

About this time pantomime also began to appear on the German stage; but their Harlequin bore as little resemblance of the Italian gentleman without bones, as a bear does of a monkey. They called him *hans roursi*, in plain English, jack-pudding. Mr. Addison has remarked, that most nations have expressed their delight in this witty personage, by bestowing upon him the appellation of their favourite food. In one instance, however, he is unfortunate, by supposing that the Dutch term corresponds with our *pickled herring*; whereas, in the original, *pickel heeren* implies a facetious little master.

PERIOD IV.

At length the German drama gradually became worthy of attracting the attention of Europe. Gottsched, anxious to redeem his country from dramatical barbarism and low buffoonery, about the year 1740 produced his *Cato*, constructed in imitation of the French regular drama. This tragedy deserves, however, very little praise; it is feeble and languid; faults not to be redeemed by the merit of regularity. Not contented with exercising his pen in this laudable design, he used his personal influence and advice; and the theatre of Leipzig, where he resided, became one of the best in Germany. A remarkable circumstance relative to that theatre must not be omitted: it is said, that for some time the company of actors there consisted of only one family; the father being manager, while the mother, the sons, the daughters, and the sons-in-law, shared the labours of the stage; and gave complete satisfaction to an audience not accustomed to severe criticism, nor disposed to exchange their cheap and easy pleasure for the vanity of finding fault.

Prior to this epoch, people of rank and taste had been accustomed to attend only the French and Italian representations; leaving the German drama to the *Bourgeoisie*, to whose uneducated taste its plain morality and gross buffoonery were adapted. But when Gottsched had been followed by Bodmer, Schlegel, Gellert, Klopstock, and others, who either produced original pieces, or good translations from the Dutch, the Italian, the Danish, and the English, and particularly from the French, the case became changed; and the German stage began to share the favour of the noble, the opulent, and the learned. By degrees the French drama, which had at first delighted by its regularity of plot, and artificial concatenation of scenes, began to disgust by its monotony; and the English theatre, which, with less regularity and art, presents far more variety and animation, obtained the preference. Almost the whole plays of Shakpeare were clothed in the Teutonic language; and even feeble transfusions of his wonderful page obtained the warm applause of a foreign audience.

Miraturque moros fructus, et non sua poma.

To the plays of Shakpeare, and the novels of Richardson, modern German dramatists appear to be deeply indebted; but it is not the intention of this slight essay to criticize the

late celebrated productions of the German theatre, many of which have been translated into English, and have become generally known. It is sufficient to have arranged these few notices, concerning the origin and progress of the German drama.

When Gottsched was endeavouring to reform the German drama, about the year 1740, he asked one of the actors why they never represented any of the plays of Gryphius, a grave writer, and good dramatist, of the preceding century? The actor answered that such pieces could not be endured, because they were in verse, were too serious, and had not one buffoon to divert an audience!

When the Germans began to translate plays from the English, their most favourite pieces were our domestic tragedies, such as the *Orphan*, the *Gamester*, &c. &c. The German language seems more adapted to this kind of composition, than to the heroic and sublime.

The German Theatre, by Gottsched, was published between the years 1746 and 1750, in 6 vols. 8vo. The first volume begins with a translation of the *Thoughts of the great Fenelon*, upon the dramatic Art: but perhaps the discourse of Corneille upon the three Unities ought to have been preferred. Many of the pieces are translated from the French; such as the *Misanthrope* of Moliere, which is disfigured with the ceremonious expression of the Germans, and the *Cid* of Corneille. Some are from the Danish; for instance, the *Political Pewterer* by the celebrated Holberg, a piece somewhat similar to our *Upholsterer*. The *Drummer of Addison* is given in the second volume: and few original pieces of consequence appear till we come to the fourth volume, which contains the *Arminius* of Schlegel; and the *Unequal Marriage*, a comedy, by Madame Gottsched, &c. In the same volume is the *Banish* of Grimm, a piece that deserves to be better known. The scene is laid in Pegu in Asia; and the stage effect, and catastrophe, are conceived, and expressed, with great vigour. The fifth and sixth volumes are wholly filled with original German productions, of various merit.

All plays, say the ancient critics, must be either tragedy or comedy. Shakpeare, or some other about his age, however, added to these, history and tragi-comedy. These terms need no explanation. Modern times have invented the *Comédie larmoyante*, which is censured for producing the contrary effect to that which is peculiarly the province of comedy. This cannot be denied; but it is a great mistake to consider the tears shed at these representations as arising from grief, and perhaps it is this mistake which has occasioned the censure.

Tears are the natural consequence of being strongly affected, from whatever cause arising. We weep at Sealand's discovery of his daughter, and at the reconciliation of Lord and Lady Townly; but they are not tears of sorrow; therefore the sensation is as far distant from tragedy as comedy, but may, by accident, belong to either.

Modern times have also given birth to the sentimental comedy, which is still further removed from this species of the drama; for a grave, moral, or religious thought, is much less connected with comedy than a tender incident: indeed, as it never has the effect of fairly growing out of the piece, it may be considered as perfectly out of place.

Many of the German pieces, but especially the play of *Lovers' Vows*, cannot be made to belong to either of these classes. The character of Agatha is as much tragic as Jane Shore, and yet it is not a tragedy. Amelia is much more comic than many of our comic characters, and yet it is not a comedy. The incidents all tend to fill the mind with those sensations which produce tears; but yet we cannot call it a crying comedy, and most certainly these tears cannot with

propriety be referred to tragic feelings, nor are we satisfied to call it a *tragi-comedy*. It is, in our opinion, a new species of drama, and this is easier said than to define its principles. The author possibly might wish to give a story with such tender sentiment, such tragic adventure, and such comic character, as might naturally belong to it, and held tragedy and comedy equally from his design. If we judge from immediate perception, we find a great deal to commend, and but little to censure.

It may not be improper to add to the many modern variations from the ancient drama, that union of romance, magic, music, and spectacle, which at present has taken such firm possession of the stage as almost to exclude the old tragedy and comedy. If amusement be the end of theatrical representations, it is undoubtedly best attained by a variety of attraction. If feelings of a better sort are to be gratified, it must be by the drama as it was invented by the Greeks, continued by the Romans, and practised, with many improvements, on the theatres of modern Europe.

DRAMBURG, a town of Germany, in Upper Saxony, 40 miles S.E. of Colberg, and 118 N.E. of Berlin.

DRAPER (Sir William), was a gentleman who distinguished himself much in the war that was conducted with such spirit and success by Pitt. He is supposed to have received his grammar learning at Eton, and to have completed his education at the King's College, Cambridge. After going through the regular gradations of service, he was employed about the period of the capture of Fort St. David's, to raise a regiment of foot (the 79th) to serve in the East Indies. The regiment was soon completed at Chelmsford, in Essex; and Colonel Draper, while the regiment lay in that town, exhibited the model of an excellent officer, not merely by the strictest attention to military evolutions and discipline, but by taking care to inculcate in his men a becoming reverence for the Supreme Being, as well as of the necessity of a life of sobriety and decorum. That they might not want, moreover, the best means of instruction, he purchased, at his own expence, a large number of bibles and common-prayers, to be distributed among them. In 1759 he behaved with the greatest gallantry at Madras; and to his efforts, in conjunction with those of Colonel Laurence and Major Breton, the raising of the siege of that important fortress was owing. In 1760 he returned to England; and, in 1761, he was promoted to the rank of brigadier-general in the expedition against Belleisle. Being sent again to the East Indies, he conducted, in conjunction with Admiral Cornish, the expedition against Manila, the capital of the Philippine Islands, which surrendered on the 6th of October, 1763, and was preserved from plunder by a ransom of four millions of dollars, which, however, the Spaniards never paid. The colours taken at this place were presented to King's College, Cambridge, and hung up, with proper solemnity, in its beautiful chapel. The services of Colonel Draper were rewarded by a red ribbon; and, upon the reduction of his regiment, the 79th, which had served so gloriously in the East Indies, his majesty, unsolicited, gave him the 10th regiment of foot as an equivalent. This he resigned to Colonel Giltborne, for his half pay, 1200*l.* Irish annuity. In 1769 we find him a literary character engaged in defence of his friend the Marquis of Granby, in a contest with the celebrated political writer Junius. Unequal perhaps to his antagonists, he claimed nevertheless the praise of excellence in this kind of writing. In October of the same year, he made a voyage to South Carolina for the recovery of his health, and took that opportunity of making the tour of North America. He married, in this year, Miss De Lancey, the daughter of the chief justice of New-York. She died, July 1778, leaving him a

VOL. X.

daughter, born in 1773, who survived her father and enjoyed an ample fortune which came to her from her mother's relations. In 1779, Sir William Draper, having then the rank of lieutenant-general, was appointed lieutenant-governor of Minorca. During the siege of that important place, he was unfortunately upon ill terms with the governor-general Murray, and, upon their return to England, the conqueror of Manila exhibited 29 charges against the gallant veteran of Quebec. The court-martial deemed 27 frivolous and groundless, and for the other two the governor was ordered to be reprimanded; which order was remitted, and Sir William Draper then ordered to make an apology to the general for having instituted the trial against him: this Sir William did, and afterwards lived in retirement at Bath. He died January 8, 1787.

DRAWING (*Enceyl.*). The following is extracted from the specification of a patent granted to Mr. Gueff, of Portsmouth, for his invention of certain boxes of a new construction, of various forms and sizes, to contain materials and other necessary articles for drawing and painting, to be arranged on scientific principles. It is dated June 2, 1801, and runs thus:

"My said invention consists of a new box or boxes, and materials, for painting and drawing, and my new manner of arranging the pallet of colours, and certain new materials that are to be contained therein, by which the art of drawing or painting in colours will be rendered more simple and generally useful, is described as follows.

"The boxes, of whatever size or shape or material they may be made, are to be so formed as to contain, with convenience, either a round, or square, or oval, or any other shaped piece of marble, or wood, or metal, or stone, or porcelain, or pottery, or glass, or other proper material or composition, or combination of materials of any kind, either coated or plain; which piece of marble, or wood, or metal, or stone, or porcelain, or pottery, or glass, or other material, is *absolutely necessary* for or to my new arrangement of the pallet of colours, and which I shall hereafter, in this specification, call by the name of a *pallet of colours*. And the box or boxes will be made subservient to it, and so contrived, that this *pallet of colours* will be sometimes fitted in the top or cover, or in a drawer, either in the front, end, or side, or some other convenient place, for the purpose of receiving it, but in such a manner that this *pallet of colours* may be easily removed, if wanted for use, by the artist or person, drawing or painting; and that the colours are to be arranged or fixed on, or let into it, by certain places being made or sunk into the pallet to receive them; and these places will sometimes be of a long square, or of an oval or a round, or indeed any other shape that may be found best adapted for the purposes intended, by which means the colours are guarded from all dirt or dust, they cannot be misplaced, the artist has no occasion to apply to a plate or other material to rub his colours on when used, the pallet on which they are arranged and fixed serving for that purpose, and which may be easily cleaned, when necessary, with a damp sponge. The colours are to be fixed, or let into the pallet, so as not to be removed, or to fall out, which is done by first caking them in the usual manner, and afterwards fastening them in, while damp, by some mucilaginous mixture, such as gum-water, or any other that will not injure them. It is hardly necessary to observe, that of whatever material the pallet be made, it should be presented in an unglazed or unpolished state: thus, if made of marble or other stone, it should be left as smooth as possible, but unpolished. If of wood, it must be coated with a composition of oil, flake white, and calx of tin, or any other composition that will answer the purpose of resisting the penetration of water, and left as smooth as possible, but not polished nor glazed. If of metal,

it should be enamelled, and ground smooth, but left with a tooth, and without polish. If of porcelain, to be left in the biscuit state. If of glass, it should, in the vitrification, be mixed with the calx of tin, or any other material that will make an opaque white enamel of it, and when made of the proper shape it should be ground, and left without polish. Let it be observed, that I do not wish to state that the colours may not be mixed on glazed or polished substances, but unglazed and unpolished bodies for that purpose are much superior.

"The convenience and utility of this *pallet of colours* every experienced and professional man will see; and it will remove the inconvenience above mentioned, which the younger practitioners have hitherto laboured under. The colours will likewise be arranged, and fixed on or into the pallet, in the following order, according to the *principia optica*, viz. The three original colours, yellow, red, and blue, will be fixed on or into the pallet, and so arranged as to shew their intermediate shades, viz. from yellow, the degrees of orange to red; from red the degrees of purple to blue, with the different degrees of green and the browns resulting from a mixture of the three original colours: which arrangements will include every possible tone or tint that can be presented to the eye, and the colours and tints will be arranged on or in the pallet, so that the numbers 1, 2, 3, &c. will indicate the tone or tint of each, and may be called yellow, orange, red, purple, blue, green, and brown, &c. without any reference to the original name of any particular pigment or chemical preparation at present in use, unlike the present method, which by naming the pigment contrary to its real tone or colour (though the experienced artist may remove the difficulties from himself), serves only to mislead the student, and those not previously acquainted with the use of colours, without conveying any idea of the tone or tint of colour wanted; but by the above arranged pallet of colours the master is eased, the student improved, and a rational and simple theory will go hand in hand with the practical part. The colours in the larger boxes, and on the larger pallets, will likewise be divided into *transparent*, or *glazing*, and *opaque*, or *body colours*. The transparent being fixed on, or let into one side, and the opaque on or into the other side of the pallet, to prevent confusion. And the transparent and opaque colours are to be arranged in the same manner with regard to the degrees of tone and situation, which will enable the artist to produce the effect he wishes, according to his style or mode of practice with the opaque; and he may, by turning his pallet, enrich and glaze his painting with the transparent colours without rendering them foul or muddy."

Having described the nature of his invention, as regards the boxes, and the *arrangement of the pallet of colours*, Mr. Gueff proceeds to state the means of rendering his invention still more convenient to the public, in adding to the boxes such articles as will supply the artist with every utensil and material that he can want; but in this it is not necessary we should follow him.

DRAYTON, a town in Shropshire, with a market on Wednesday, seated on the river Torn, which separates this county from Staffordshire. It is 17 miles N.E. of Shrewsbury, and 154 N.W. of London. Long. 2. 22. W. Lat. 52. 54. N.

DRENTELBURG, a town of Germany, in the principality of Hesse, 18 miles N.N.W. of Cassel, and 32 E.S.E. of Paderborn. Long. 8. 57. E. Lat. 51. 23. N.

DRESDEN (*Encycl.*). J. G. Lippius has published a description of the gallery of antiques, at Dresden, in a quarto volume of 526 pages, with thirty pages of tables and ten plates. The origin of this gallery is as old as the reign of

Augustus, elector of Saxony, by whose order, medals, and other remains of antiquity, were purchased in 1560. Under his successors, this collection continued to increase, till by the munificent exertions of several sovereigns it became of the highest value and importance. Till the year 1785, the collection lay scattered in different pavilions of the large garden, where it was very ill arranged, and in such a state as to be of very little use to artists. The present elector, therefore, assigned a place for it in the Japanese palace, and enriched it with several new and valuable acquisitions. M. Wacker, the inspector of this gallery, had made out a description of every thing it contains; but as he died before it was published, M. Lippius made use of his manuscript for the work there announced, and which must be of great utility to artists and amateurs, as the ten plates at the end of the volume exhibit plans on which the different articles are indicated by letters corresponding to the descriptions.

DRESSERUS (Matthew), a learned German, was born at Erfurt, the capital of Thuringia, in 1536. The first academical lectures which he heard, were those of Luther and Melancthon, at Wittenberg; but he had not the advantage of them long, because the air of that country not agreeing with his constitution, he was obliged to return to Erfurt, where he studied Greek. When he had taken the degree of M.A. in 1559, he read lectures in rhetoric at home, and afterwards taught polite literature and the Greek tongue in the college of Erfurt. When he had gone on in this way sixteen years in his own country, he was invited to Jena, to supply the place of Lippius, as professor of history and eloquence. He pronounced his inaugural oration in 1574, which was afterwards printed with other of his orations. Some time after, he went to Meissen, to be head of the college there; and having continued there six years, he obtained, in 1581, the professorship of polite learning in the university of Leipzig; and a particular pension was settled on him to continue the History of Saxony. Upon his coming to Leipzig, he found dreadful disputes among the doctors. Some endeavoured to introduce the subtleties of Ramus, rejecting the doctrine of Aristotle, while others opposed it; and some were desirous of advancing towards Calvinism, while others would suffer no innovations in Lutheranism. Dresserus desired to avoid both extremes: and because the dispute concerning the novelties of Ramus greatly disturbed the philosophical community, he was very solicitous to keep clear of it. But the electoral commissary diverted him from his pacific design; and he became the most zealous opposer of Ramism that ever was known in that country.

Dresserus spent the remainder of his life at Leipzig, where he died in 1607. He married in 1565; and, becoming a widower in 1598, he married again two years after. He was a man of great industry, and not easily tired with applying, as he shewed at Erfurt; for he brought all his colleagues, who, except one, were Roman-catholics, to consent, that the confession of Augsburg and Hebrew should be taught in the university. He was the author of several works, which now are not useful or curious enough to deserve a particular account.

DREIENEN, a town of Germany, in the new march of Brandenburg, with a strong fort, on the river Warta, 20 miles E. of Landsparg. Long. 15. 43. E. Lat. 52. 53. N.

DRINAWARD, a town of Turkey in Europe, in Servia. It stands on a small island formed by the Drino, on the confines of Bosnia.

DRINKER (Edward), was born on the 24th of December 1680, in a small cabin near the present corner of Walnut and Second streets in the city of Philadelphia. His parents came from a place called Beverly, in Massachusetts's Bay. The banks of the Delaware, on which the city of Philadelphia

now stands, were inhabited, at the time of his birth, by Indians, and a few Swedes and Hollanders. He often talked to his companions of picking waterberries, and catching rabbits, on spots now the most populous and improved of that city. He recollected the second time William Penn came to Pennsylvania, and used to point to the place where the cabin stood, in which he and his friends that accompanied him were accommodated upon their arrival. At twelve years of age he went to Boston, where he served an apprenticeship to a cabinet-maker. In the year 1745 he returned to Philadelphia with his family, where he lived till the time of his death. He was four times married, and had eighteen children, all of whom were by his first wife. At one time of his life he sat down at his own table with fourteen children. Not long before his death he heard of the birth of a grand-child to one of his grand-children, the fifth in succession from himself.

He retained all his faculties till the last years of his life; even his memory, so early and so generally diminished by age, was but little impaired. He not only remembered the incidents of his childhood or youth, but the events of later years, and so faithful was his memory to him, that his son said that he never heard him tell the same story twice, but to different persons and in different companies. His eye-sight failed him many years before his death, but his hearing was uniformly perfect and unimpaired. His appetite was good till within a few weeks before his death. He generally ate a hearty breakfast of a pint of tea or coffee, as soon as he got out of his bed, with bread and butter in proportion. He ate likewise at eleven o'clock, and never failed to eat plentifully at dinner of the grossest solid food. He drank tea in the evening, but never ate any supper. He had lost all his teeth thirty years before his death (his son says, by drawing excessive hot smoke of tobacco into his mouth); but the want of suitable mastication of his food did not prevent its speedy digestion, nor impair his health. Whether the gums, hardened by age, supplied the place of his teeth in a certain degree, or whether the juices of the mouth and stomach became so much more acrid by time, as to perform the office of dissolving the food more speedily and more perfectly, is not known; but it has been often observed, that old people are more subject to excessive eating than young ones, and that they suffer fewer inconveniences from it. He was inquisitive after news in the last years of his life; his education did not lead him to increase the stock of his ideas in any other way. But it is a fact well worth attending to, that old age, instead of diminishing, always increases the desire of knowledge. It must afford some consolation to those who expect to be old, to discover, that the infirmities to which the decays of nature expose the human body, are rendered more tolerable by the enjoyments that are to be derived from the appetite for intellectual food.

Drinking was remarkably sober and temperate. Neither hard labour, nor company, nor the usual afflictions of human life, nor the wailes of nature, ever led him to an improper or excessive use of strong drink. For the last twenty-five years of his life he drank twice every day a draught of toddy, made with two table-spoonfuls of spirit in half a pint of water. His son, a man of 50 years of age, declared he had never seen him intoxicated. The time and manner in which he used spirituous liquors, contributed to lighten the weight of his years, and probably to prolong his life.

He enjoyed an uncommon share of health, inasmuch that in the course of his long life he was never confined more than three days to his bed. He often declared that he had no idea of that most distressing pain called the head ach. His sleep was interrupted a little in the last years of his life with a de-

fluxion in his breast, which produced what is commonly called the old man's cough.

The character of this aged citizen was not summed up in his negative quality of temperance; he was a man of a most amiable temper; old age had not curdled his blood; he was uniformly cheerful and kind to every body; his religious principles were as steady as his morals were pure; he attended public worship above thirty years in the Rev. Dr. Sprout's church, and died in a full assurance of a happy immortality. The life of this man is marked with several circumstances which perhaps have seldom occurred in the life of an individual; he saw and heard more of those events which are measured by time, than have ever been seen or heard by any man since the age of the patriarchs; he saw the same spot of earth in the course of his life covered with wood and bushes, and the receptacle of beasts and birds of prey, afterwards become the seat of a city, not only the first in wealth and arts in the new, but rivaling in both many of the first cities in the old world. He saw regular streets where he once pursued a hare; he saw churches rising upon morasses, where he had often heard the croaking of frogs; he saw wharfs and warehouses where he had often seen Indian savages draw fish from the river for their daily subsistence; and he saw ships of every size and use in those streams where he had been used to see nothing but Indian canoes; he saw a stately edifice filled with legislators on the same spot, probably, where he had seen an Indian council fire; he saw the first treaty ratified between the newly-confederated powers of America and the ancient monarchy of France, with all the formalities of parchment and seals, on the same spot, probably, where he once saw William Penn ratify his first and last treaty with the Indians without the formalities of pen, ink, or paper; he saw all the intermediate stages through which a people pass from the most simple to the most complicated degrees of civilization; he saw the beginning and end of the empire of Great Britain in Pennsylvania.

He had been the subject of seven crowned heads, and afterwards died a citizen of the newly-created republic of America, Nov. 17, 1782, aged 102.

DRINO, a river of Turkey in Europe, which has its source on the frontiers of Albania, and falls into the bay of Drino, in the gulf of Venice.

DRINO, a sea-port of Turkey in Europe, on a bay of the same name, in the gulf of Venice, 50 miles S.E. of Ragusa. Long. 10. 19. E. Lat. 42. 48. N.

DROME, a department of France, including part of the late province of Dauphiny. It is so called from a river of the same name.

DRONERO, a town of Piedmont, seated at the foot of the Alps, on the river Macra, over which is a bridge of prodigious height, 14 miles S.S.W. of Saluzzo.

DRONFIELD, a town in Derbyshire, with a market on Thursday. It is situate at the edge of the Peak, in so wholesome an air, that the inhabitants commonly live to a great age; and it is therefore much resorted to, and has many fine buildings. It is 28 miles N. of Derby, and 155 N.W. of London. Long. 1. 25. W. Lat. 53. 18. N.

DRONTHEIM, a city of Norway, capital of a government of the same name, with an archbishop's see, and a good harbour. It carries on a great trade; is almost surrounded by the sea and the river Piddet; and it is 270 miles N.W. of Stockholm. Long. 11. 9. E. Lat. 63. 26. N.

DROSENDORF, a town of the Archduchy of Austria, on the Taya, 46 miles N.W. of Vienna. Long. 15. 38. E. Lat. 48. 45. N.

DROSSEN, a town of Germany, in the new march of

Brandenburg, 12 miles S.E. of Cuftrin, and 14 E. of Frankfurt on the Oder.

DROWNED LANDS, a valuable tract of about 50,000 acres, in the state of New York, on the N. side of the mountains, in Orange County. The waters which descend from the surrounding hills, being slowly discharged by the river Wallkill, cover these vast meadows every winter, and render them extremely fertile; but they expose the inhabitants in the vicinity to intermittents. The river Wallkill, which passes through this extensive tract, and falls into Hudson's River, is, in the spring, very plentifully stored with large eels.

DROWNING (*Encycl.*). To what has been said already, we think it of importance to add Dr. Cullen's observations on this subject.—“With respect,” says he, “to the particular means to be employed for the recovery of drowned persons, it is to be observed, in the first place, That such as were recommended and practised, upon a supposition that the suffocation was occasioned by the quantity of water taken into the body, and therefore to be evacuated again, were very unhappily advised. The hanging up of persons by the heels, or setting them upon the crown of the head, or rolling the body upon a cask, were generally practised, upon a supposition altogether false; or upon the supposition of a case which, if real, is apprehended to be irrecoverable. At the same time, these practices were always attended with the danger of bursting some vessels in the brain or lungs, and of rendering thereby some cases incurable, that were not so from the drowning alone. All such practices, therefore, are now very properly disapproved of and forbid.

“In those cases in which the body has not been long in the water, and in which therefore the natural heat is not entirely extinguished, nor the irritability of the moving fibres very greatly impaired, it is possible that a good deal of agitation of the body may be the only means necessary to restore the action of the vital organs; but in other cases, where the heat and irritability have ceased to a greater degree, it is to me very doubtful, if much agitation can be safe, and if any degree of it can be useful, till the heat and irritability are in some measure restored. In all cases, any violent concussion cannot be safe, and, I believe, is never necessary. It may be proper here to observe also, that, in transporting the body from the place where it is taken out of the water, to the place where it may be necessary for applying the proper means of its recovery, all postures exposing to any improper compression, as that of the body's being carried over a man's shoulder, are to be avoided. The body is to be kept stretched out, with the head and upper parts a little raised; and care is to be taken to avoid the neck's being bent much forward. In this manner, laid upon one side, and upon some straw in a cart, it may be most properly conveyed; and the agitation which a pretty brisk motion of the cart may occasion, will, in most cases, do no harm.

“From the account I have given above of the causes, or of the appearances, of death, in drowned persons, it is evident, that the first step to be taken for their recovery is to restore the heat of the body, which is absolutely necessary to the activity of the moving fibres. For this purpose, the body, as soon as possible, is to be stripped of its wet clothes, to be well dried, and to be wrapped up in dry, and (if possible) warm, coverings: and it is to be wished, in all cases, as soon as the report of a person's being drowned is heard, that blankets should be immediately carried to the water-side; so that, as soon as the body is got out of the water, the change of covering just now mentioned may be instantly made; or, if the body has been naked when drowned, that it may be immediately dried, and

defended against the cold of the air. Besides covering the body with blankets, it will be further of advantage, if it can be done without loss of time, to cover the drowned body with a warm shirt or waistcoat immediately taken from a living person.

“When, at the time of a person being drowned, it happens that the sun shines out very hot, I think there can be no better means of recovering the heat, than by exposing the naked body, in every part, to the heat of the sun; while, at the same time, all other means necessary or useful for the recovery of life are also employed.

“When the heat of the sun cannot be employed, the body should be immediately transported to the nearest house that can be got convenient for the purpose: the fittest will be one that has a tolerably large chamber, in which a fire is ready, or can be made; and, if possible, the house should afford another chamber, in which also a fire can be provided.

“When the drowned body is brought into such house, and care is at the same time taken that no more people are admitted than are absolutely necessary to the service of the drowned person, every endeavour must be immediately employed for recovering the heat of the body, and that by different measures, as circumstances shall direct.

“If, in the neighbourhood of the place, there be any brewery, distillery, dyery, or fabric, which gives an opportunity of immediately obtaining a quantity of warm water and a convenient vessel, there is nothing more proper than immersing the body in a warm bath. Even where a sufficient quantity of warm water cannot be had at once, the bath may be still practised, if the accident has happened in or very near a town or village, when a great many fires may be at once employed in heating small quantities of water; for in this way the necessary quantity may be soon obtained. To encourage this practice, it is to be observed, That one part of boiling water is more than sufficient to give the necessary heat to two parts of spring or sea-water, as it is not proper to apply the bath at first very warm, nor even of the ordinary heat of the human body, but somewhat under it; and, by the addition of warm water, to bring it gradually to a heat very little above it.

“If the drowned body be of no great bulk, it may be conveniently warmed by a person's lying down in bed with it, and taking it near to their naked body, changing the position of it frequently, and at the same time chafing and rubbing with warm clothes the parts which are not immediately applied to their warm body.

“If none of these measures can be conveniently practised, the body is to be laid upon a bed before a moderate fire, and frequently turned, to expose the different parts of it; and thus, by the heat of the fire gradually applied, and by rubbing the body well with coarse towels, or other cloths well warmed, pains are to be taken for restoring its heat. This will be promoted by warm cloths applied and frequently renewed under the arms and arm pits; and by hot bricks, or bottles of warm water, laid to the feet.

“In the practice of rubbing, it has been proposed to moisten the cloths applied with camphorated spirits, or other such stimulating substances: but I think this must prove an impediment to the rubbing; and I would not recommend any practice of this kind, except, perhaps, the application of the volatile spirit of sal ammoniac to the wrists and ankles only.

“For recovering the heat of the body, it has been proposed, to cover it all over with warm grains, ashes, sand, or salt; and where these, sufficiently warm, are ready at hand, they may be employed; but it is very seldom they can be ob-

^{Food.}
(Digestion.)
^{ETC.}

Diet. Selections from "Dr. Christ's Practical Treatise on Diet."

Fowls. - These afford a more wholesome and delicate diet than quadrupeds. It is easier also of digestion; but they afford at the same time a less proportion of real nourishment. Nor is their nourishment so general as that of quadrupeds, some parts of them being always tough & unsipid from their manner of life. Of birds a greater number of the Carnivorous kinds are eaten than of quadrupeds; but they are indeed chiefly those that live on fish, from which indeed they acquire a peculiar taste, but this is by no means so unpleasant as that of Carn^{iv}-^(quadrupeds) animals.

The time of using fowls requires more to be studied than that of quadrupeds, as they frequently are out of season, particularly in spring, when they pair; & where they are birds of passage, or migrate from one place to another, they require some rest & residence, or to be in case before they are fit for use. Fowls are improved by domestication in two ways, by making them 'barndoor fowls', or by cramping them, that is shutting them up for the sole purpose of

feeding them. These arts of ~~feeding~~ ^{feeding} no doubt give more succulence & tenderness to the food and increase its alkalescency. From giving succulence they are an improvement; but from increasing alkalescency, they render the food more unfit for weak stomachs & Convalescents, by whom this species of food is much used, though at the same time they render it more easy of (digestion?) Solution. Exercise is necessary to give perfection to all food, for by this means the fat of the animal is equally distributed through the muscular parts; while, when fatted hastily, it is accumulated in the cellular membrane. By the domestication, also, of fowls in general, their peculiar flavour, on which their excellence depends is lessened, and by cramming them it becomes entirely lost. Hence also, unless their fibres are very tough, roasting is to be preferred to boiling them, on the same account.

Salmon, not too old or too young, it is of a tender substance, sufficiently succulent & nourishing, but rather oily & heavy on stomach. —

Salmon Trout = do + soft & gelatinous

Pike = short, compact & close (in its parts) flesh

river pike best
= least heating
hard of digestion

tained, and the application might often interfere with other measures that may be necessary. All therefore that I can propose, with respect to the use of these, is to observe, that bags of warm and dry salt may be amongst the most convenient applications to the feet and hands of drowned persons: and the quantity necessary for this purpose may be got pretty quickly by heating the salt in a frying-pan over a common fire.

"While these measures are taking for recovering the heat, means are at the same time to be employed for restoring the action of the moving fibres. It is well known, that the intestines are the parts of the body which, both from their internal situation and peculiar constitution, retain the longest their irritability; and therefore, that, in drowned persons, stimulants applied may have more effect upon the intestines than upon other parts. The action, therefore, of the intestines is to be supported or renewed as soon as possible; as the restoring and supporting the action of such a considerable portion of moving fibres as those of the intestines, must contribute greatly to restore the activity of the whole system.

"For exciting the action of the intestines, the most proper mean is, the application of their ordinary stimulus of dilatation; and this is most effectually applied, by forcing a quantity of air into them by the fundament. Even the throwing in cold air has been found useful; but it will certainly be better if heated air can be employed; and further, if that air can be impregnated with something which, by its acrimony, also may be powerful in stimulating the intestines.

"From all these considerations, the smoke of burning tobacco has been most commonly applied, and has upon many occasions proved very effectual. This will be most properly thrown in by a particular apparatus, which, for other purposes as well as this, should be in the hands of every surgeon; or at least should, at the public expence, be at hand in every part of the country where drownings are likely to happen. With regard to the use of it, I have to observe, that till the tobacco is kindled in a considerable quantity, a great deal of cold air is blown through the box and tube; and as that, as hinted above, is not so proper, care should be taken to have the tobacco very well kindled, and to blow through it very gently, till the heated smoke only passes through. If, upon certain occasions, the apparatus referred to should not be at hand, the measure however may be executed by a common tobacco pipe, in the following manner: A common cyfler-pipe that has a bag mounted upon it, is to be introduced into the fundament, and the mouth of the bag is to be applied round the small end of a tobacco-pipe. In the bowl of this, tobacco is to be kindled; and, either by a playing card made into a tube and applied round the mouth of the bowl, or by applying upon this the bowl of another pipe that is empty and blowing through it, the smoke may be thus forced into the intestines, and, in a little time, in a considerable quantity.

"If none of these means for throwing in the smoke can be employed, it may be useful to inject warm water to the quantity of three or four English pints. This may be done by a common cyfler-bag and pipe, but better by a large syringe; and it may be useful to dissolve in the water some common salt, in the proportion of half an ounce to an English pint; and also, to add to it some wine or brandy.

"While these measures for recovering the heat of the body and the activity of the moving fibres are employed, and especially after they have been employed for some time, pains are to be taken to complete and finish the business, by restoring the action of the lungs and heart.

"On this subject, I am obliged to my learned and ingenious colleague, Doctor Monro, who has made some experiments for ascertaining the best manner of inflating the lungs

of drowned persons. By these experiments he finds it may be more conveniently done by blowing into one of the nostrils, than by blowing into the mouth. For blowing into the nostril, it is necessary to be provided with a wooden pipe, fitted at one extremity for filling the nostril, and at the other for being blown into by a person's mouth, or for receiving the pipe of a pair of bellows, to be employed for the same purpose. Dr. Monro finds, That a person of ordinary strength can blow into such a pipe with a sufficient force to inflate the lungs to a considerable degree; and thinks the warm air from the lungs of a living person will be most conveniently employed at first; but when it is not soon effectual in restoring the respiration of the drowned person, and that a longer continuation of the inflation is necessary, it may be proper to employ a pair of bellows, large enough at once to contain the quantity of air necessary to inflate the lungs to a due degree.

"Whether the blowing-in is done by a person's mouth, or by bellows, Dr. Monro observes, that the air is ready to pass by the gullet into the stomach; but that this may be prevented, by pressing the lower part of the larynx backwards upon the gullet. To persons of little knowledge in anatomy, it is to be observed, that the pressure should be only upon the cricoid cartilage, by which the gullet may be frightened, while the passage through the larynx is not interrupted.

"When, by blowing thus into the nostril, it can be perceived, by the raising of the chest or belly, that the lungs are filled with air, the blowing-in should cease; and, by pressing the breast and belly, the air received into the lungs should be again expelled; then the blowing and expulsion should be again repeated: and thus the practice is to be continued, so as to imitate, as exactly as possible, the alternate motions of natural respiration.

"It is hardly necessary to observe, that when the blowing into the nostril is practised, the other nostril and the mouth should be accurately closed.

"If it should happen, that, in this practice, the air does not seem to pass readily into the lungs, Doctor Monro informs me, it is very practicable to introduce directly into the glottis and trachea a crooked tube, such as the catheter used for a male adult. For this he offers the following directions: The surgeon should place himself on the right side of the patient; and, introducing the forefinger of his left hand at the right corner of the patient's mouth, he should push the point of it behind the epiglottis; and using this as a directory, he may enter the catheter, which he holds in his right hand, at the left corner of the patient's mouth, till the end of it has passed beyond the point of his forefinger; and it is then to be let fall, rather than pushed into the glottis; and through this tube, by a proper syringe applied to it, air may be with certainty blown into the lungs. I observe, that some such method had been proposed by Mons. Le Cat in France; but I have not learned that it has ever been put in practice, and I am afraid it may be attended with several difficulties, and must be left to the discretion of surgeons, who may be properly provided and instructed for this purpose.

"For throwing air with more certainty into the lungs, it has been proposed to open the windpipe in the same manner as is done in the operation which the surgeons call *bronchotomy*, and by this opening to blow into the lungs; and when the blowing into the nostril does not seem to succeed, and a skilful operator is at hand, I allow that the measure may be tried; but I can hardly suppose, that it will be of any advantage when the blowing-in by the nostril has entirely failed.

"It is to be hoped, that by blowing into the lungs one way or other, even a quantity of water which had been taken into the lungs may be again washed out; and the same seems to

be the only effectual means of washing out that frothy matter which is found to fill the lungs of drowned persons, and which proves, if I mistake not, the most common cause of their mortal suffocation. This practice, therefore, is to be immediately entered upon, and very assiduously continued for an hour or two together.

"I have now mentioned the measures chiefly to be pursued and depended upon for the recovery of drowned persons; but must still mention some others that may prove considerable helps to it.

"One of these is, the opening the jugular veins to relieve the congestion, which almost constantly occurs in the veins of the head, and is probably a frequent cause of the death of drowned persons. For relieving this congestion, the drawing some blood from the jugulars, very early, may certainly be of service; and it will be particularly indicated by the livid and purple colour of the face. It may even be repeated, according to the effect it seems to have in taking off that suffusion; but when the drowned person is in some measure recovered, and some motion of the blood is restored, it will be proper to be very cautious in making this evacuation, and at least to take care not to push it so far as to weaken too much the recovering, but still weak, powers of life.

"Another measure for recovering the activity of the vital principle, is the application of certain stimulants to the more sensible parts of the body, such as holding the quick-lime spirit of sal ammoniac to the nose, or putting a little of it upon a rag into the nostrils. It has been usual to pour some liquids into the mouth; but it is dangerous to pour in any quantity of liquid, till it appear that the power of swallowing is in some measure restored.

"When a surgeon is at hand, and is provided with proper apparatus, a crooked pipe may be introduced into the gullet; and by this a gill or two of warm wine may be poured down into the stomach, and probably with advantage. But when no such apparatus is at hand, or surgeon to employ it, and the power of swallowing is still doubtful, the trial of pouring liquids into the mouth should be made by a small quantity of warm water alone; and when, from such trial, the power of swallowing shall appear to be recovered, it may then be allowable to favour the further recovery of the person, by pouring in some wine or brandy.—In short, till some marks of the recovery of swallowing and respiration appear, it will not be safe to apply any stimulants to the mouth, excepting that of a few drops of some acid substance to the tongue, and which are not of bulk enough to slide back upon the glottis: I can think of no stimulant, more conveniently and safely to be applied to the mouth and nostrils, than a moderate quantity of tobacco-smoke blown into them.

"Though I do not imagine that drowned persons are ever hurt by the quantity of water taken into their stomach, yet, as a stimulus applied to the stomach, and particularly as the action of vomiting proves a stimulus to the whole system, I can have no objection to the French practice of throwing in an emetic as soon as any swallowing is restored. For this purpose, I would successively throw in some tea-spoonfuls of the ipecacuanha wine; and, when it does not interfere with other necessary measures, the fauces may be gently irritated by an oiled feather thrust into them.

"With regard to the stimulants, I must conclude with observing, That when a body has lain but for a short time in the water, and that therefore its heat and irritability are but little impaired, the application of stimulants alone has been often found effectual for the recovery: but, on the contrary, when the body has lain long in the water, and the heat of it is very much extinguished, the application of any other stimu-

lants than that of tobacco-smoke to the intestines can be of very little service; and the application of others ought never to interfere with the measures for recovering heat and the motion of respiration.

"With respect to the whole of these practices, I expect, from the principles upon which they are in general recommended, it will be understood, that they are not to be soon discontinued, though their effects do not immediately appear. It is obvious, that, in many cases, it may be long before the heat of the body, and the activity of the vital principle, can be restored, although, in a longer time, it may very possibly be accomplished. In fact, it has often happened, that though means, employed for one hour, have not succeeded, the same continued for two or more hours, have, at length, had the wished-for effects. It should therefore be a constant rule, in this business, that the proper means should be employed for several hours together; unless it happen, that, while no symptoms of returning life appear, the symptoms of death shall, at the same time, go on constantly increasing.

"In the whole of the above I have kept in view chiefly the case of drowned persons: but it will be obvious, that many of the measures proposed will be equally proper and applicable in other cases of suffocation; as those from strangling, the damps of mines, the fumes of charcoal, &c.; and a little attention to the difference of circumstances will lead to the measures most proper to be employed."

Mr. Hunter, in the before-mentioned paper, differs pretty considerably from De Haen and Dr. Cullen. He observes, that when assistance is soon called in after immersion, blowing air into the lungs will in some cases effect a recovery; but when any considerable time has been lost, he advises stimulant medicines, such as the vapour of volatile alkali, to be mixed with the air; which may easily be done, by holding spirits of hartshorn in a cup under the receiver of the bellows. And, as applications of this kind to the olfactory nerves tend greatly to rouse the living principle, and put the muscles of respiration into action, it may probably, therefore, be most proper to have air impregnated in that manner, thrown in by the nose. To prevent the stomach and intestines from being too much distended by the air so injected, the larynx is directed to be gently pressed against the oesophagus and spine. But having detailed, in our original article, the means to be employed for the recovery of the drowned, we shall here close this part of the subject, and proceed to describe the implements represented in Pl. 25. to be employed in searching for the bodies of drowned persons when sunk in the water.

Fig. 1, is a forked instrument with blunt points, for making a superficial search after the drowned body, and sounding the particular situation in which it sunk.

Fig. 2, a ladder with a long, jointed handle, and which we have already mentioned (*Supp.* p. 403), when treating of the Ice-boats: a model of these boats may be inspected in the Repository of the "Society for the Encouragement of Arts, Manufactures," &c. Adelphi, London.

Fig. 3, An extractor, or a linked pair of tongs, which in the plate appears closed; but, on immersing it into water, opens by its own weight, as well as by the sliding down of the iron ring *o* from the part marked *x* to that of *u*. It may again be closed, by pulling the double rope fastened to the ring *o*, which is thus thrust upward from *u* to *x*: by means of expanding the iron arms *an*, which are likewise connected with this ring, the mouth or flaps of the instrument *rr* may be shut: and to prevent their opening till required, the two ropes are firmly tied round the iron bolt *ss*; in which situation they remain till the body is extracted.—This instrument, together with that represented, Fig. 4, cost about 2l. at Hamburg.

Great attention is required in preserving them from the effects of rust; and, independently of the weight of iron-work, fig. 3 is perhaps the most complete piece of machinery that can be contrived for this purpose.

Description of the Engraving in which the "Implements of respiration from drowning" are represented (Pl. 25).

Fig. 1. A pair of bellows with two separate bags, so contrived that by opening them, when applied to the nostrils or mouth of a patient, one bag will be filled with common air, and the other with the mephitic air extracted from the lungs; and, by shutting them again, pure atmospheric air will be introduced into these organs, and that drawn out consequently discharged into the room. Thus, the artificial breathing may be continued, while the other operations on the surface of the body are carried on; which could not be conveniently done, if the muzzle of a common pair of bellows were introduced into the nostril.

a, Is an intermediate board, but which admits of no communication between the two bags. In the external board of each side, there is the usual hole, marked *b*, provided with a valve; and the cylindrical part through which the air is expelled in common bellows, is here folded to a copper box, within which two other valves are applied to the tubes conducting the air. The cover *d* of this box, which may be unscrewed by means of an interposed leather ring, is almost of the shape of a funnel, to the neck of which is fastened a flexible tube *e* made of varnished silk cloth, and a spiral wire that forms the cavity. To the extremity of this tube is attached a small ivory pipe *f*, the front of which may either be tubular and round, for introducing it into the nostril; or flat, like the top-piece of a clarinet, if it be intended for the mouth. The valves (which cannot be represented in a plate) consist of stiffened taffety, and are so arranged, that the corresponding ones stand in an inverted order. If, therefore, both bags of the bellows be expanded, *two* of the valves open themselves towards the internal part of the machine: one of these is fixed to one of the side-boards, but the other is within the box, on the mouth of the conducting tube belonging to the opposite bag of the bellows. By this contrivance, the air enters both bags of the bellows at the same time, and is, on compression, again expelled by means of two other valves, which open from within toward the external parts. Both bags of the bellows terminate below the valve in one principal tube of communication; because, though the action of both bellows is *simultaneous*, the stream of air, conformably to the arrangement before pointed out, can only enter, and escape, *alternately*.—In using this machine, the small ivory pipe is applied either to one of the nostrils, or put into the mouth: in the former case, the other nostril and the mouth must be closed; in the latter, both nostrils. When the bellows are set in action, one of the bags receives a column of atmospheric air through its valve; while the other, by means of its flexible tube and its valve, extracts a portion of air from the lungs. But, if the bellows are again shut, one of the bags parts with the impure gas drawn out of the pulmonary vessels; and the second conveys pure atmospheric air to the organs of respiration. By properly repeating this alternate process, the patient may again be enabled to exercise the important function of breathing. As, however, a precipitate and irregular method of proceeding might be productive of injury, this delicate operation ought to be performed by persons who are acquainted with the mechanism of respiration.—In some cases, where the patient has, for a considerable time, lain under water, or was afterwards neglected for want of due assistance, it would be desirable to introduce into his lungs *oxygen*, or pure vital dephlogisticated air, instead of that of the common atmosphere; as the latter is generally more or less cor-

rupted on such occasions by the breath of many persons in the same room. For this purpose, may be used a bladder, marked *g*, which is provided with a cock and pipe fitted or screwed to the board of the inspiring valve and bag of the bellows. If, therefore, after opening the cock, the machine is set in motion; it will extract the pure air contained in the bladder, and, on the subsequent compression of the bellows, force it into the lungs of the patient.

Fig. 2. A machine for injecting the smoke of tobacco by way of clyster, in those desperate cases which require the application of this remedy. It consists of a pair of bellows, to the muzzle of which is fitted a metal box, *a*, provided with a ring, in the middle of which it may be unscrewed, and again closed, after being filled with tobacco, and set on fire: the pipe *c* (which, by mistake, is represented with a sharp point in our plate, but should be perfectly round and blunt at the top) of the flexible tube *b*, is introduced into the fundament; and thus, by means of the bellows *d*, the smoke is forced into the rectum.

Fig. 3. A bier of wicker-work, in the form of a slanting, oblong basket, for conveying the body of the drowned, in a posture somewhat raised. This simple contrivance has the advantage, that the water may easily run off, while the patient is carried: and, as many unfortunate persons are materially injured by rough treatment, before they arrive at a house of reception, so that their recovery is thus often frustrated, we recommend the universal adoption of this useful implement. It costs at Hamburg only ten marks currency, or about 15s.

Fig. 4. The *Warning Machine* of block tin, or other metal, was originally invented by Mr. Harvey, of London, who suggested it to our Royal Humane Society, and it was subsequently improved by M. Braich, an ingenious mechanic of Hamburg. Its object is to procure an uniform degree of warmth, throughout the apparatus, in the most expeditious manner, by filling the hollow or double bottom and sides of the whole implement with boiling water.—*a* is the body of the machine, seven feet long, and made of solid pieces of block-tin, to prevent the necessity of folding them, and consequently the formation of iron-rust: it rests on two wooden legs *ff*, and may be easily carried by the handle *gg*. The water is poured in through both funnels *d, d*, in order to warm it more speedily; and each of these is provided with a stopper (as represented in the plate, suspended on a chain), with a view to prevent, if necessary, too sudden evaporation and cooling of the water:—*h* is the intermediate space between the two metallic plates, producing a vacuum of 2½ inches, in which the fluid is diffused over the whole machine:—*b* is a wooden desk to support the head of the patient, and to protect it from the immediate contact with the heated parts; but, on the opposite end of the machine, there is an enlarged intermediate space, *c*, for holding such a quantity of water and vapours as will procure an additional, or at least a more permanent, degree of heat towards the lower extremities, than to the trunk of the body. For discharging the water, when it is not wanted, or changing it when too cold, there is a cock at *e*. The hollow sides of this machine are about twelve inches high; and in order to ensure an uniform warmth, the body apparently dead should be placed on a straw mattress, and tucked in with blankets. A pailful of water is required to fill the whole machine, as a smaller quantity would warm the sides only for a short time, by means of the vapour.

It deserves to be remarked, that this ingenious contrivance may also be used for a *warm bath*; for which purpose, the inner space in which the body lies, should be supplied with water. The whole apparatus, in its present improved state,

made of copper, costs at Hamburg about 200 marks, or from 14 to 15*l*.

Lastly, we cannot conclude this subject without affording the reader a view of the different articles belonging to a complete chest of instruments, and other materials, employed in the various processes for recovering suspended animation from drowning. The merit of these institutions in England, is due to Drs. Cogan and Hawes, the founders of the Royal Humane Society at London; but the improved arrangement of the chest now to be described, together with the choice of internal and external remedies, were made by a respectable surgeon at Deptford, Mr. Kite, in 1788, though considerably extended in 1790, by Mr. Redlich, medical practitioner of respectability at Hamburg. This gentleman is likewise one of the most active members of the Humane Society in that city, and has offered the following articles for sixty-five marks, or about four guineas and a half. His complete chest contains :

A small bottle of rectified spirit of wine.

Ditto, white-wine vinegar.
Ditto, sweet oil.
Ditto, white French brandy.
Ditto, volatile sal ammoniac.
Ditto, vitriolic æther.
Ditto, mustard-feed.

A machine for injecting the smoke of tobacco.

A leather tube, together with a pair of bellows, for inflating the lungs.

Another tube of leather, for introducing medicines into the stomach.

A small syringe for clearing the throat of mucus.

Three woollen covers or blankets.

Four brushes, and six woollen cloths, for performing friction.

Several emetics.

Two lancets for blood-letting.

One pound of tobacco.

A roller and cushion, to be used in venesection.

Two quills, a sponge, and some lint.

A pocket-knife.

An apparatus for striking fire.

Chamomile and elder-flowers.

Common salt :—and a printed copy (in German) of rules and directions for treating the drowned.

Conceiving that a chest containing all these articles could not be purchased in London for less than double the price above stated, beside the additional trouble of procuring them, we have borrowed this account from our respectable fellow-labourer, the Editor of the Domestic Encyclopedia ; especially as the commercial intercourse between Hamburg and this country is daily increasing.

On Thursday, 15th October, 1801, trial was made on the river Thames, off Greenwich Hospital, in presence of several respectable gentlemen, of a copper tube, invented by Lawrence Collin, brazier and tinman, for floating the heaviest person, though unacquainted with swimming, having his feet at rest, while the arms might be freely used out of the water. The instrument can be fixed by any person on himself in about half a minute, and keeps him upright in the water ; so as to have the full use of his hands ; and he may either float on his side, back, or belly, with his hands and feet at rest, or take a sitting posture, with his legs at right angles to his body. This instrument, which is called a *collinette*, may be made portable of copper, tin, or leather. The weight of the copper one, with which the late successful trial was made, was about five pounds ; but if leather can be well manufactured so as to resist the fluid and retain atmospheric air, it would be so light, that no person going on an excursion on

the water would be without one of them. In cases of shipwreck, many lives that would otherwise perish would be saved, since a dozen or twenty of these instruments might facilitate the means of extending ropes to a lee-shore, and thereby save a numerous crew. A certificate was given to the ingenious inventor by the gentlemen before whom the trial was made.

DRUMBOTE, a town of Ireland, in the county of Monaghan, eight miles W. of Dundalk. Long. 6. 31. W. Lat. 54. 10. N.

DRUMLANRIG, a town in Dumfriesshire, in the district of Nithdale ; remarkable for a wood of oak six miles in length. Here is a noble seat of the Duke of Queensbury, screened by woody hills, and adorned with beautiful gardens. In one of the parks here, Mr. Gilpin saw a few of the wild cattle which anciently inhabited the woods of Scotland. Drumlannrig is seated on the river Nith, 13 miles N. of Dumfries. Long. 5. 31. W. Lat. 55. 25. N.

DRUNKENNESS (*Encycl.*). To save the lives of persons who are in danger of dying from having drank large draughts of any spirituous liquors, Dr. Houlston recommends *diluting it in the stomach* by pouring in, through a tin tube, or even a common funnel, carefully passed into the *throat*, large quantities of water.

DRUSENHEIM, a fortified town of France, in the department of Lower Rhine, seated on the river Moser, near the Rhine, five miles S.E. of Haguenau.

DRYDEN (John). Notwithstanding we have already introduced the life of this great poet in our third volume, and that at some length, the following account of his life and writings, extracted from Mr. Malone's recent publication of Dryden's Critical and Miscellaneous prose Works, abounds with so many curious circumstances, not recorded by any other of his biographers, that we are tempted to present it to our readers without alteration.

In whatever point of view he is contemplated, whether as a poet, a critic, or a man, the character of Dryden is highly interesting, and the labour undertaken for the purpose of making him better known, is entitled to the most grateful consideration. Mr. Malone's account of this distinguished ornament of British literature is a specimen of laudable exactness, the fruit of an unwearied solicitude to render the desire of describing elegantly subservient to the necessity of recording truly. The diligence employed in tracing genealogies, comparing dates, and searching amid the records of public offices, has afforded a topic for the sarcasms of some men whose vivacity outruns their judgment ; but those who know how to appreciate truth, and who feel its importance in matters apparently minute, will discriminate between raillery and argument, and not suffer the momentary illusion of a fanciful image to divert their attention from those objects which, in biography and criticism, afford the greatest, perhaps the only genuine, satisfaction. To narrate on trust, and repeat, without any other novelty than that of expression, the hackneyed falacies of preceding writers, is indeed a mean servility ; but if, in order to avoid this disgrace, a writer of more judgment and industry takes the pains to explore those recesses in which truth lies concealed, his meed of fame ought to be commensurate with the extent of his labour : the dust which affords occasion to sneer, constitutes rather a title to glory ; nor can the laurel be ignobly worn which is tarnished with the dust of Shakspeare and of Dryden. It is not the intention of this essay to criticise Mr. Malone's work, but as the account of Dryden, which he has supplied, corrects many misstatements received by Dr. Johnson, and adopted by his successors, and records many new facts, it would have appeared unjust to omit that laudatory notice which the subject so fairly claimed. Let it not, however, be considered that the errors of Johnson

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

are irreverently mentioned. Mr. Malone is so perfectly sensible of the great talents of that illustrious biographer, that he has purposely avoided all critical discussion of the merits of Dryden, from a conviction that such an examination may be well dispensed with, after Dr. Johnson's elaborate and admirable disquisition; than which a more beautiful and judicious piece of criticism, perhaps, has not appeared since the days of Aristotle. On the subject of Johnson's mistakes, Mr. Malone thus expresses himself:—"When I mention these slight inaccuracies of Dr. Johnson, for whom personally when living I had the greatest respect and veneration, and for whose writings I have the highest admiration, I hope not to be misunderstood. Such trivial errors can diminish little from the value of his incomparable Lives of the Poets, and, as I have elsewhere observed, but with to repeat it here, are merely specks in the finest body of criticism extant in any language."

John Dryden was the eldest son of Erasmus, third son of Sir Erasmus Driden*, bart. and Mary, daughter of the Rev. Henry Pickering. The time of his birth is uncertain, it is commonly supposed to have been the 6th of August, 1631, but the date thus assumed rests only a mistake in the quarto edition of Pope, published in 1735, where the inscription on Dryden's tomb is erroneously given. Nor is the account correct which fates the stock of his family to have been in the county of Huntingdon; it was in Cumberland. The place of his birth was Aldwinlee, in Northamptonshire. He received the first rudiments of learning at Tichmarsh, and probably was indebted for part of his education to the school at Oundle. From one of these seminaries he was removed to Westminster, where he was admitted a king's scholar, under the tuition of the celebrated Dr. Busby; he was contemporary with Locke, South, Dr. Henry Stubbe, Dr. Walter Pope, Dr. John Mapletot, Henry Bagshaw, and Edward Bagshaw. While at Westminster he gave proof of his extraordinary talent, by translating the third satire of Persius for a Thursday night's exercise; but the tradition which assigns to him the celebrated pentameter on the miracle of changing water into wine,

"Lympha pudica Deum, vidit et erubuit."

is unfounded. The line is found, with a slight variation, in an epigram on the subject by Richard Crafshaw, published in his *Epigrammata Sacra*, 1634. At Westminster, Dryden, in 1649, made his first attempt in English poetry, by a copy of verses on the death of Lord Hastings, which are disgraced by the conceits usually found in the poetry of that period.

He was elected to one of the scholarships of Trinity College, Cambridge, where he was admitted the 11th of May, 1650, and matriculated the 6th of July. In the same year, he wrote some commendatory verses, prefixed to the poems of John Hoddedon. It is erroneously asserted that Dryden obtained no degree; he was made a bachelor at the regular time in January 1653-4, and in 1657 was made master of arts, but did not obtain a fellowship in his college. It has excited surprise that his name is not found in any of the Cambridge verses composed in his time on public occasions, but that sensation is removed by the accuracy of Mr. Malone; from him we learn, that only one general collection of verse was issued out by the university of Cambridge during the unfortunate and disgraceful period of Dryden's being a

member. It appeared in August or September, 1654, under the title of *Oliva Pacis*, &c. To this volume Dryden might have been expected to contribute; but his father died in June, 1654, and the necessity of attending him during his last illness, and the coincidence of the academic vacation, account for his apparent omission of an opportunity to display his poetic talent.

The patrimony to which he now succeeded, did not induce him to abandon his studies. He returned to the university, but his habits and modes of life cannot be ascertained. In all probability the fair sex, who even at seventy "still inspired his wit," then claimed much of his attention, and gave occasion to some productions of his muse, which are now lost. Mr. Malone has recovered a letter written about the year 1655, to Honour Dryden, the poet's cousin, containing a copy of amatory verses, distinguishable only for those conceits which were the vice of the age.

In 1657, after residing seven years at Cambridge, he removed to London. On the credit of one of that host of foes whom his subsequent celebrity excited, it has been believed that he quitted the university from fear of being expelled for a libel on a nobleman's son, but there is no evidence of this fact, nor any probability in the circumstances by which it is supported. He had staid at the university three years beyond the usual period, and had reason to expect advancement from the influence of his relation Sir Gilbert Pickering, who was extremely intimate with Oliver Cromwell.

What benefits he derived from this connection are not known; the death of the Protector destroyed his prospects, and gave a subject to his muse. He produced "Heroic Stanzas on the Death of Oliver Cromwell," which were published separately in the beginning of 1659, and afterwards united with the verses of Waller and Sprat on the same occasion. Like many other panegyrics of the usurper, he with equal facility paid homage to the restored monarch, and in 1660 published *Alfreda redux*, a Poem on the happy Restoration of his most sacred Majesty. Both these productions gave promise of greater efforts.

Dryden is represented by his enemies to have been now a mere literary drudge under Herringman the bookseller, and to have been reduced to dine at a three-penny ordinary, till raised to affluence by his connection with Sir Robert Howard; but this account is obviously fictitious, founded only on the circumstances of his intimacy with Howard, to whose poems, printed for Herringman in 1660, he prefixed some encomiastic verses. His own fortune was sufficient to preserve him from a state so abject. It was probably through Sir Robert that Dryden became acquainted with Lady Elizabeth Howard, daughter of Thomas earl of Berkshire, whom he married about the year 1665. The libellers of the poet have asserted that the circumstances attending this match were not honourable to either party. Johnson repeats the allegation, but evidence of a better kind is not found, and the proof rests principally on the sarcasms with which the poet occasionally alluded the marriage state.

In 1661 he addressed A Panegyric to the King on his Coronation, and on New Year's-day, 1662, An encomiastic Poem to the Lord Chancellor Clarendon. In 1663 he prefixed some elegant lines to his friend Dr. Charleton's *Ac-*

* Dryden changed the orthography of the family name; for some time he wrote it Dreyden: this licence gave great offence to his relatives.

† Anderson says 6th August.

‡ See Andrews's Anecdotes, p. 290.

§ They are not noticed by Johnson. Anderson mentions them in his Life of Dryden, but they are not found among the poems Mr. Malone has given them, p. 14.

count of Stonehenge. A tribute was paid to his rising reputation, by electing him a member of the newly-instituted Royal Society, 19th November, 1662.

We now enter on Dryden's dramatic career: Eusden, Gildon, Jacob, and others, have expressed surprise at his tardiness in beginning, as he produced no play till after he had attained his thirtieth year. But these persons did not reflect that from 1640 to 1660 plays were not permitted, and Dryden himself informed a more attentive peruser, that in the very year of the restoration he began his first play, *The Duke of Guise*. This piece being shown to his friends, was not deemed sufficiently correct for representation, and, therefore, it was kept back for some years.

In February 1662-3, his first play, *The Wild Gallant*, was put on the stage. It was only saved from total condemnation by the Councils of Cuddecombe, afterwards Dukes of Cleveland, to whom he addressed some verses on the occasion.

Mr. Malone divides Dryden's dramatic life into four periods: 1. From his outset as a play-writer to the temporary suspension of dramatic exhibitions in 1665. 2. From their revival to the time when the king's theatre was destroyed by fire in 1671-2. 3. From that era to 1682, when he discontinued writing for the stage. 4. From 1690 to 1694, in which period his last five plays were produced. In the first period, besides the *Wild Gallant*, Dryden wrote *The Rival Ladies*, in 1663; he assisted Sir Robert Howard in the *Indian Queen*, and wrote the *Indian Emperor*, acted in 1664-5.

The plague broke out soon afterwards, and in consequence of that, and the fire in 1666, dramatic entertainments were suspended for eighteen months. During this interval, Dryden married, and resided principally in the country. Here he amused himself by writing his elegant *Essay of Dramatic Poesy*; it is a colloquy between Eugenius, Crites, Liffideus, and Neander. By Eugenius was represented Charles lord Buckhurst, afterwards earl of Dorset; Crites was Sir Robert Howard; Liffideus, Sir Charles Sidley (commonly called Sedley), transposed from Sidleyus; and Neander, Dryden himself. In this retirement he seems to have projected, and perhaps written, his poem in quatrains, called *Annus mirabilis*, which was published in 1667. He also wrote *Secret Love*, or the *Maiden Queen*, and revised his unsuccessful drama, *The Wild Gallant*.

Soon after the recommencement of dramatic exhibitions in London, Dryden took a more secure method of obtaining emolument than the patronage of any individual, however elevated by rank or fortune, could afford; that of contracting with the king's theatre for an annual stipend, on condition of furnishing a certain number of plays in each year. The emolument was agreed to be one share and a quarter, out of twelve shares and three quarters, into which the theatrical stock was divided; the number of plays to be supplied was not four, as Johnson, misled, perhaps, by the Key to the Rehearsal, has stated, nor two, as Cibber has advanced, but three. The mistakes which have prevailed respecting this contract, have given rise to many stories of Dryden's writing for bread, and producing three, four, and even six, plays in a year. Malone, by a more accurate investigation, disproves these fallacies: between 1667 and 1674, that is, in about seven years, Dryden produced but ten plays; and if the examination is extended to a later period, December 1682, it will be found that in sixteen years he had written but eighteen. The era of his greatest exertion seems to have been from 1667 to 1670; in which period probably he wrote five or six plays. This statement is important to the fame of Dryden, for his facility and elegance of composition are recorded by so many indubitable facts, that they can derive no advantage from fiction.

On the death of Sir William d'Avenant, April 7th, 1668,

Dryden was made Laureat, but not immediately, as has been supposed; he did not obtain the appointment till the 18th of August, 1670. The death of James Howell in 1666; occasioned a vacancy in the office of Historiographer, which was also conferred on Dryden. The patent granted him the salary of 200*l.* a-year retroactively from Midsummer 1668, with the privilege of receiving each year a butt of canary wine from the king's cellars at Whitehall.

The conduct of Dryden and Sir Robert Howard towards each other is considered, by Dr. Johnson, as not easily to be explained. They disagreed on the subject of writing plays in rhyme; and as the contest was carried on with great earnestness in several publications, a degree of rancour ensued, but the interposition of friends and the placability of Dryden, facilitated a reconciliation, and they continued ever after on good terms.

From the re-opening of the theatres in the beginning of the year 1667, to the middle of 1670, Dryden produced five original plays, and two in which he was assisted by others. The five are: *The Maiden Queen*; *The Mock Astrologer*; *Tyrannic Love*, or the *Royal Martyr*; and the *Conquest of Grenada*, in two parts. The others are, *The Tempest*, altered from Shakspeare, in conjunction with d'Avenant; and *Sir Martin Mar-all*, translated from the French by the Duke of Newcastle, and revised for the stage by Dryden.

He was now sufficiently eminent to be an object of envy, and on the 7th of December, 1671, the Rehearsal was produced. This play was the joint production of George Villiers duke of Buckingham; Martin Clifford, master of the Charter-house; Butler, Sprat, and others; and is stated to have engaged their attention for ten years. An examination of its merits would extend this sketch to too great a length, and may, therefore, occupy a separate paper. It is a mistake that the success of the Rehearsal banished plays in rhyme from the stage; they continued to be acted for many years, and several pieces condemned in it were afterwards revived with applause.

Dryden, though he never answered the Rehearsal, had the good sense and forbearance not to oppose the current, and in 1672 produced two comedies, *Marriage à la Mode*, and *The Assignation*, or *Love in a Nunnery*; the first was successful, the latter damned. In 1673, he wrote *Amboyna*, for the purpose of exasperating the nation against the Dutch. After the production of these pieces the author seems to have suspended his dramatic labours, for *The State of Innocence*, published in 1674, could not have been intended for a stage exhibition. It is said that before he entered on this task, Dryden waited on Milton, and asked leave to turn his poem into rhyme; "Aye," said the blind bard, "you may tag my verses if you please."

As the *State of Innocence* only employed a month, Dryden had full leisure for the composition of *Aurengzebe*, which was acted in 1675. Charles II. perused the piece in manuscript, and "the most considerable event it was modelled by his royal pleasure." In 1676 and 1677 he was engaged in writing *All for Love*, and the comedy of *Limberham*. All for Love, Dryden says, was the only play he wrote for himself, the rest were given to the people. *Limberham* expired on the third night: various reasons are alleged for its want of success; the author attributes it to his having "expressed too much of the vices it decries;" Langbaine suggests that it was condemned for exposing the *keeping* part of the town. It has also been affirmed that in the character of *Limberham*, Dryden had Lord Shaftesbury particularly in view, and his partisans contributed to its fate.

Dryden's contract with the king's company was dissolved about this time, in consequence of disagreements, the causes of

which cannot now be discovered. Limberham was acted by the rival company, as well as *Œdipus*, written in conjunction with Lee, about 1679, and Truth found too late, altered from Shakespeare's *Troilus and Cressida*. His next play, *The Spanish Friar*, was acted with great success about February 1681-2. The two companies of players, called the King's and Duke's, now united, and Dryden furnished a prologue and an epilogue on their opening the theatre, 16th November, 1682. On the 30th was performed *The Duke of Guise*, of which Lee contributed two-thirds. The subject of this play was political, and the aim of it, to form a parallel between the leaguers of France and the Scottish covenanters. For some time after this, Dryden was chiefly occupied in political controversy; this, therefore, terminates the third portion of his dramatic life.

In this period Dryden was at first patronised, and afterwards persecuted, by the fickle and profligate Rochester, who raised up as rivals Otway, Settle, and Crowne. Dryden's sensibility was excited to a degree which prudence did not justify by the temporary success of Settle's *Empress of Morocco*, in contributing to which, Rochester contrived to occasion some personal affronts to the laureat. After his controversy with Settle, a sufficient specimen of which is preserved by Johnson, Dryden, in conjunction with the Duke of Buckingham, wrote *An Essay on Satire*, in which Rochester was treated with great severity. In revenge, on the 18th of December, 1679, he caused Dryden to be way-laid, and cudgelled, as he was returning home from Will's, through Rose-street, Covent-garden. As *Louise de Querouaille*, duchess of Portsmouth, was also mentioned in terms of great contempt in this production, it is supposed to have joined with Rochester in his revenge.

The constant labour in which he was engaged for the theatres, hindered Dryden from turning any great portion of his attention to productions either in poetry or prose which were not of a dramatic form. From the year 1667 to 1680 he wrote only a few papers of verses, and translated two epistles of Ovid—*Canace to Macareus*, and *Dido to Æneas*; to which may be added, that from Helen to Paris, which he englightened in conjunction with Lord Mulgrave. He often lamented his servile drudgery, and traced the plan of two epic poems, either of which would not only have immortalised the author, but have been an inestimable addition to the stock of British literature. The subject proposed for the one was the Conquest of the Saxons by King Arthur; the other that of Edward the Black Prince subduing Spain, and restoring it to Don Pedro, the lawful sovereign. This noble design he was never sufficiently at ease to execute.

In 1681 he relieved and diversified his dramatic pursuits by that exquisite political satire, *Abraham and Achitophel*, which he is said to have undertaken at the express desire of the king, and calculated to have completed in nine months. It was read with such avidity, that in four years six editions were published; a prodigious circulation in those days. In the second edition, twelve new lines were added to the character of Shaftesbury, in which he was praised for his integrity and discernment as chancellor. This circumstance gave rise to a report, that the poet received a bribe for his complaisance; and others assert that he was actuated by gratitude for Shaftesbury's liberality in nominating his son to a scholarship in the Charter-house, without any solicitation. This story is disproved by the laudable diligence of Mr. Malone, who has ascertained that Dryden's son was not admitted at the Charter-house till after Shaftesbury's death, and then, at the recommendation of the king. The added lines were, in fact, a mere amplification of the same thought less clearly expressed in the first edition of the poem.

On the 24th of November, 1681, the Grand Jury at the Old Bailey returned *ignoramus* on the bill presented against

Shaftesbury, and he was taken from the Court-house with shouts of applause, which lasted for an hour. To perpetuate their triumph on this occasion, his adherents soon afterwards employed George Bower, an able sculptor, to engrave a medal in commemoration of that event, which gave rise to Dryden's poem, entitled *The Medal*, or a *Satire against Sedition*. The king suggested the subject, while walking in the Mall with Dryden, and made him a present of a hundred broad pieces when it was finished. It was composed with vigour and poignancy, equal to *Abraham and Achitophel*.

While he attacked with such vigour and success, Dryden was necessarily exposed to the efforts of many opponents. A poem, entitled *Dryden's Satire to his Mule*, which appeared about this period, is said to have given him some uneasiness. The author was never ascertained: it was ascribed to Lord Somers, but he disclaimed all knowledge of it. Among the foremost of Dryden's avowed adversaries, was Shadwell, a poet of very little talent, and who had been in some degree protected by the poet-laureat, for whom he frequently avowed his friendship. In his former satires, Dryden took no notice of the inferior retainers of the whig party, but, at length, roused by repeated injuries, he discharged his resentment against Shadwell, in the poem called *Mac Flecknoe*; an admirable satire, which afforded him an ample triumph over his corpulent antagonist, and afterwards formed the model of the *Dunciad*. This poem was published the 4th of October, 1682. It has been erroneously asserted by Dryden's biographers, Dr. Johnson not excepted, that this poem proceeded from the poet's resentment at being succeeded in the laureathip by Shadwell, but it was published upwards of six years before that event took place. Although he might seem in this great effort to have exhausted the whole quiver of satire, he returned to the charge in less than a month, and in the second part of *Abraham and Achitophel*, which was published November the 10th, 1682, exposed Shadwell, under the name of Og, to additional contempt, with every grace of variety, and the same charms of novelty, which characterised his first attack. Under the appellations of Doeg, Judas, and Ben Jochanan, he stigmatised Settle, Ferguson, and Samuel Johnson, and at the same time punished three or four scribblers of inferior note. All these characters are wrought with no less felicity than those of Zimri and Achitophel. The rest of the poem, which has great merit, is written by Tate.

In the same month, Dryden produced his *Religio Laici*, a sensible and well-written poem, highly deserving attentive and frequent perusal. At this period began his intimacy with Southerne, which ended only with his life. He was also constantly attached to the unfortunate Lee, who was generally called by his contemporaries, "Honest Nat Lee," and after his infamy, "Poor Nat Lee." Having now discontinued writing for the stage, and the state of the exchequer not permitting a regular discharge of his stipend, Dryden became seriously distressed, and addressed Lawrence earl of Rochester, to remove at once his apprehensions of poverty, by assigning to him a place in the customs or the excise, but, to the disgrace of the age, neither his poetry nor his loyalty were sufficient recommendations to ensure success.

Yet did he not resign himself to unmanly despair, or permit his enemies to triumph over the misery resulting from an union of poverty and indolence. He translated, by the king's command, *De Maimbourg's History of the League*, which appeared in 1684; and, in the mean time, wrote a Preface and Life of the Author to a new translation of *Plutarch's Lives*, which was then undertaken by a number of persons. He also, in 1683-4, published the first volume of his *Miscellanies*, containing translations of detached pieces, from Virgil, Horace, and Theocritus, and some of his smaller poems, together with

occasional prologues and epilogues already published. Early in 1685 he published a second volume of Miscellanies.

A few days afterwards he was deprived of his gracious protector and patron, Charles II. whose death he consecrated in a pindaric ode, or elegy, called, *Threnodia Augustalis*. Before this event, Dryden had finished a political opera, called *Albion and Albanus*; it was rehearsed before the king, who expressed himself highly pleased, and the poet probably formed great expectations from its success. It was afterwards performed, but always unfortunate. On the sixth night, the 13th of June, 1685, during the representation, news arrived that the Duke of Monmouth was landed in the west; the playhouse was immediately deserted, and the piece was not again produced*.

Soon after King James the Second's accession, Dryden was converted to popery. The bulk of mankind, ever happy to credit such allegations as tend to diminish the pride of genius, have imputed this change to sordid motives, but there is no reason for such a charge. In the early part of his career, Dryden, like his contemporaries, laughed at religion and derided priests. When he wrote *Religio Laici*, he was advanced in years, but seems rather to have been impressed with the grand truths of Christianity, than attached to any particular church; the poem was rather occasional than the fruit of long premeditation, as it was addressed to a friend who had recently translated Father Simon's *Critical History of the Old Testament*. In the reign of King Charles, religion was left to make its own impression on the minds of individuals, but after the accession of James, converts were assiduously sought, and no means were left for evading religious discussion. Dryden's wife was suspected to be a papist; her brother Charles, the second earl of Berkshire, undoubtedly was one; and thus surrounded and biased, it is not surprising that the poet, now first called upon to choose a creed, chose that of Rome. He could not have done so on speculative probabilities, and of certain reward he does not appear to have had a promise. He knew how great a triumph he was going to afford his enemies, but yet pursued the dictates of his conscience: he might, after the Revolution, have retained the situation of Laureat and Historiographer, and have insured splendid patronage by a time-serving re-conversion, but constantly refused to do any thing derogatory to his principles, or injurious to his honour.

Dryden's attachment, at a period when the Duke of York was very unpopular, entitled him to expect from his accession to the throne the provision he had before solicited. But he only obtained a pension of one hundred pounds a-year, which was granted by letters patent dated the 4th of March, 1685-6. About this time he wrote his much-admired Ode on the death of Mrs. Anne Killegrew, and a Poem to Northleigh, author of the *Parallels*.

He also entered into a controversy with Dr. Stillingfleet, in defence of a paper, written by Anne Hyde, duchess of York, in vindication of her change of religion; and he is said to have entertained a design of translating Mous. Varilla's *History of Heresies*, but to have abandoned it.

In 1687 Dryden published *The Hind and the Panther*, the longest of his original poems. It was read with avidity, and speedily went through three or four editions. It is an allegorical dialogue between the churches of Rome and England, represented by two beasts, the first milk-white, unpotted, and unchanged; the other beautiful, but spotted. The thought was not fortunate, though the poem contains many beauties.

Such an argument conducted by such personages afforded a fine subject for ridicule; and one of the happiest efforts in this way was *The Country Mouse and City Mouse*, transferred from the Hind and the Panther. This was the production of Charles Montague, afterwards earl of Halifax, and Matthew Prior, but chiefly the latter: Dryden felt this attack with great sensibility, and was the more hurt as it proceeded from two young men whom he had always treated with great civility.

During the latter years of King James, and immediately after the Revolution, Dryden seems to have relaxed in his efforts; he did not publish so much; but probably perceiving himself to be unpopular, and the season unfit, he preferred a delay, which would be ultimately beneficial. In 1687 he wrote his first Ode on St. Cecilia's day, which was set to music by Giovanni Baptista Draghi; and in June, 1688, produced *Britannia Rediviva*, an ode on the birth of the prince, afterwards known by the title of the Pretender. In the same or the preceding year, he wrote, in Hudibrastic verse, and with great vigour and sprightliness, *An Epistle to Sir George Etherege*, on his being appointed envoy to Ratibon. He was also a subscriber to the folio edition of Milton, published in 1688, by Jacob Tonson, and supplied that elegant Epigram which has ever since accompanied the picture of the author of *Paradise Lost*.

After the Revolution, an oath became necessary to be taken by those who held certain offices; Dryden could not take this oath, and was therefore deprived of his places of Laureat and Historiographer, which he had the mortification to see bestowed on Shadwell.

He was now compelled again to direct his attention to the theatre, and in 1690 produced *Don Sebastian*, which was acted with great success. In the same year he brought out *Amphytrion*, altered from Plautus and Moliere, which was equally well received. King Arthur was written before the death of Charles II. but not acted till 1691; it was set to music by Purcell, and formed a popular entertainment: it still keeps possession of the stage, under the name of Arthur and Emmeline. In the summer of 1691; Dryden was employed in writing the tragedy of *Cleomenes*; but being prevented by illness from finishing it, he assigned it to the care of his friend Southerne, and it was acted in May 1692. About December 1693, he concluded his dramatic labours with *Love Triumphant*, a tragi-comedy, which was damned on the first representation.

Having thus quitted the stage, of which, with only a few intervals, he had kept possession one-and-thirty years, producing seven-and-twenty pieces, which included every species of dramatic composition; he was compelled for the last ten years of his life to exert himself with increased activity to keep off poverty, the bitterest enemy of genius. In 1691 he wrote a Preface to Walf's *Dialogue on Women*, and an Elegy on the Death of the Countess of Abington, whom he had never seen, but whom he celebrated under the name of Eleanora. In 1692, assisted by his two sons and some of the contemporary poets, he gave to the world a complete translation of Juvenal and Persius; and he wrote for his friend Sir Henry Sher, who had translated Polybius, a *Life of that historian*. In 1693 he published his third *Miscellany*, and appears to have translated from the Greek, the poem of *Hero and Leander*, but it was not printed, and the manuscript cannot be found. He

* Dr. Johnson has inadvertently transferred this anecdote to a piece afterwards written by Dryden, called *Prince Arthur*; the mistake was noticed by Anderson.

† To this must be added, that in the course of his life he wrote near a hundred Prologues and Epilogues of extraordinary merit.

also assisted Congreve, to whom he was much attached, in preparing the *Old Bachelor* for representation, and wrote a commendatory copy of verses on the *Double Dealer*. In 1694, Tonson published a volume under the title of the *Annual Miscellany*, to which Dryden contributed only a version of the third *Georgic* of Virgil and an Epistle to Kneller.

He now commenced his most arduous literary labour, the complete translation of Virgil. Many efforts were made to induce him to undertake this task, and the nation seemed to consider its honour interested in the event: Mr. Gilbert Dolben gave him the various editions of his author; Dr. Knightly Chetwood furnished him with the *Life* of Virgil, and the Preface to the Pastorals; and Addison supplied the arguments of the several books, and an Essay on the *Georgics*. The first lines of this great poet which he translated, he wrote with a diamond on a pane of glass in one of the windows of Cheterton-house, in Huntingdonshire, the residence of his kinsman and namesake, John Driden, esq. The version of the first *Georgic* and a great part of the last *Æneid* was made at Denham-Court, in Buckinghamshire, the seat of Sir William Bowyer, baronet; and the seventh *Æneid* was translated at Burligh, the noble mansion of the Earl of Exeter. These circumstances endear those places to the votaries of the muses, and give them a kind of celebrity which neither the beauties of nature nor the exertions of art can bestow. The work was printed by subscription, as *Paradise Lost* had been some years before, and Wood's *Athenæ Oxoniensis* in 1691. Dryden completed this great task in three years, and not in six, as Pope has asserted. For this translation, which Pope with justice pronounced the most noble and spirited translation that he knew in any language, Dryden acquired, at the utmost, but 1396l. 12s. 6d. Swift, who hated Dryden, though he might have derived honour from their relationship, derides him for dedicating the different parts of his works to three several patrons. The practice was not new; as Spenser, Chapman, Fuller, and others, had done the same. Dryden has been often censured for the praises which he lavished on his patrons, but that was the vice of the times. Every dedicatior did the same, and Dryden in that instance, as in most others, shewed a pre-eminence in facility and elegance. Tonson was extremely anxious that the *Æneid* should be dedicated to King William, and made the engraver who retouched the old plates used by Ogilby, always represent the hero with a hooked nose*; but the poet, persevering in his attachment to King James, refused to offer incense to his successor. The translation was published in July 1697, and the whole impression was sold, and a new edition demanded, in the course of a year.

From the time employed in this great work, Dryden borrowed two months in 1695, to translate Du Fresnoy's *Art of Painting*, and in the same year he wrote *An Ode on the Death of Purcell*. In the next year he wrote the *Life of Lucian*, to

be prefixed to a translation of his works, which was not published till after Dryden's death.

In 1697, at the solicitation of the stewards of the Anniversary Musical Festival, he wrote the celebrated ode called *Alexander's Feast*, a poem which transcends all praise, and places the British lyric poetry above that of any other nation. It does not, however, appear to be true, that it was composed and finished at one sitting; nor is this circumstance necessary to insure our admiration of a poem which alone would have sufficed to immortalise its author. It was first composed by Jeremiah Clarke, afterwards by Clayton, and lastly by Handel.

In March 1697-8, Jeremy Collier, a non-juring clergyman, published his *Short View of the Immorality and Profaneness of the British Stage*, in which he pointedly attacked Dryden, Congreve, and Vanburgh. The two latter defended themselves; but Dryden, with great candour, acknowledged such parts of his works as were reprehensible, and merely advanced circumstances in extenuation. He at this time meditated a translation of Homer, and by the experiment of the first *Iliad* was led to believe the Grecian bard a poet more according to his genius than Virgil.

In the middle of 1698 he began to modernise Chaucer, and having completed two-thirds of his undertaking, contracted in the spring of 1699 to furnish his bookseller with ten thousand verses for three hundred pounds. The accomplishment of this task gave to the public that beautiful collection of poetry known by the name of *Dryden's Fables*, which was published in March 1699-1700. About this time one of his friends having revised Fletcher's *Pilgrim* for the stage, stipulated that Dryden should have the benefit of the third night's performance, which was allowed, in consequence of his supplying a prologue and epilogue, a dialogue between two mad lovers, and other additions.

Conceiving that the seventeenth century ended with the year 1699, Dryden wrote a secular masque to be presented at the end of this play, which was to have been performed on the 25th of March, the day when the new year then began. If Dryden was mistaken in this particular, he did not live to see the eighteenth century. He had for some years been harassed with the gravel and gout, and in December 1699 was afflicted with an erysipelas in one of his legs. He recovered sufficiently to resume his labours, but in March and April was again confined, and in consequence of neglecting an inflammation in one of his feet a mortification ensued. He refused to submit to an amputation, and having taken an affectionate leave of his friends, died with perfect composure, and in the profession of the Roman-catholic religion, on the 1st of May, 1700.

He was interred in Westminster-abbey, after laying in state ten days, on Monday, the 13th of May; his funeral was splendid, and most honourably attended†. A monument was

* This circumstance gave rise to the following Epigram, which is preserved among the Harleian MSS. in the British Museum:

"To be published in the next edition of Dryden's Virgil:

Old Jacob, by deep judgment sway'd,
To please the wise beholders,
Has plac'd old Naisan's hook-nos'd head
On poor *Æneas*'s shoulders.

To make the parallel hold tack,
Methinks there's little lacking;
One took his father pick-a-pack,
And t'other sent his packing."

† An account was printed thirty years after his death, of a scene of riot and indecorum excited by Lord Jefferies, but this is proved to be a mere fiction, invented by a Mrs. Elizabeth Thomas, better known by the name of Corinna, who founded her narrative on a letter of Farquhar. The unravelling of this invention does great credit to Mr. Malone's sagacity, and merits perusal as an antidote against literary credulity.

erected by Sheffield duke of Buckingham, in 1720, with a short Latin inscription.

Soon after Dryden's death, Henry Playford, a publisher of music, solicited the followers of the muses to express their sorrow for the loss of so great a poet, and was, in less than two months, enabled to publish a collection of English and Latin verses, under the title of *Lucus Britannici, or the Tears of the British Muses for the Death of John Dryden*. This was preceded or followed by several separate elegies, and a collection of plaintive verses, entitled the *Nine Muses*, written by nine ladies.

In person, Dryden was short and fat, with a florid complexion. He is supposed by Mr. Malone not to have been so entirely deficient in talents for conversation as is generally believed. His being a constant frequenter of Will's coffee-house, in Russel-street, Covent-garden, is too well known to be circumstantially repeated. He lived in Gerard-street; his house was the fifth on the left hand in coming from little Newport-street. His predilection for astrology is mentioned by all his biographers*, and he had some faith in oneirocriticism, or the prognostication of future events by dreams.

Dryden does not appear to have been happy in marriage, which, considering the acknowledged sweetness and placability of his disposition, could hardly be considered his fault. His wife was remarkable for a waywardness of temper, which ended in a total derangement of intellect, and in that state she survived till the year 1714. By this lady, Dryden had three sons, Charles, John, and Erasmus Henry, all of them fine, ingenious, and accomplished gentlemen.

The education of these three young men, in which their father was honourably liberal, occasioned many of the complaints of poverty found in his works, for a more selfish man might have accumulated considerable sums with the same advantages. His paternal estate was worth 40*l.* a-year. On his marriage with Lady Elizabeth Howard, an estate in Wiltshire was settled on her, which is computed at 60*l.* a-year. From the theatre his emoluments may be calculated at 100*l.* and during his contract at 200*l.* a-year. In 1670 he was made poet-laureat and historiographer, and from that period to the end of 1676, his income was about 557*l.* per annum, equal to, at least, 1500*l.* in these times. From 1685 to 1689 he derived nothing from the stage, but his salary was increased to 300*l.* and that, with his own estates augmented by the death of his mother, made 420*l.* or full 1200*l.* a-year. In August 1689 his distress truly began; for being then deprived of his places, his revenue was reduced to 120*l.* a-year, with contingent accessions derived from his literary exertions, or the benevolence of his patrons. But distress could never make him deviate from the honourable firmness of his principles, though a prospect of immediate reward presented itself as a motive. "The court," he says in a letter to Mrs. Steward, dated 7th November, 1699, "rather speaks kindly of me, than does any thing for me, though they promise largely; and perhaps they think I will advance as they go backward; in which they will be much deceived, for I can never go an inch beyond my conscience and honour. If they will consider me as a man who has done my best to improve the language, and especially the poetry, and will be content with my acquiescence under the present government, and forbearing satire on it, that I can promise, because I can perform it; but I can neither take the oaths, nor forsake my religion."

This copious extract will place many points of Dryden's character and literary history in a new light, and sufficiently

excuse us with the reader for introducing it: but an ample fund of information and delight awaits the readers of Mr. Malone's elegant publication; the biography abounds in anecdote, and just and useful discussion; and the prose of Dryden is enriched with notes remarkable for learning, good taste, and critical acumen.

DUAREN (Francis), professor of civil law at Bourges, was born at St. Erien, a city of Bretagne in France, 1509. He was the son of John Duaren, who exercised a place of judicator in Bretagne; which place he succeeded his father in, and performed the functions of it for some time. He read lectures on the *Pandects* at Paris, in 1536; and, among other scholars, had three sons of the learned Budæus. He was sent for to Bourges in 1538 to teach civil law, three years after Alciat was retired; but quitted his place in 1548, and went to Paris, in order to frequent the bar: for he was very desirous to join the practice to the theory of the law. He attended the bar of the parliament of Paris, but conceived a prodigious aversion to the chicanery of the court: disgusted therewith, Duaren had great reason to rejoice at the advantageous offers made him by the *Duchess of Berri*, sister of Henry II. which gave him a favourable opportunity to retire from the bar, and to resume with honour the employment he had at Bourges. He returned to his professorship of civil law there, in 1551; and no professor, except Alciat, had ever so large a stipend in the university, as himself. He seems to have deserved it: for to his honour it may be said, that he was the first of the French civilians who cleared the civil-law chair from the barbarism of the glossators, in order to introduce the pure sources of the ancient jurisprudence. He was indeed unwilling to share this honour with any person; and therefore viewed with an envious eye his colleague Eguinard Baron, who blended likewise polite literature with the study of the law. This jealousy prompted him to write a book, in which he endeavoured to lessen the esteem the world had for his colleague; however, after the death of Baron, he shewed himself one of the most zealous to immortalize his memory, and erected a monument in honour of the deceased at his own expence. He had other colleagues, who revived his uneasiness. He could not behold without pain the great reputation of *Baldunus* or *Baudouin*, who was younger than himself; and, after he was delivered from that thorn, he perceived, that *Cujacius*, who succeeded Baudouin, had still greater merit. He did not at all lose this new-comer; and there arose between them such disputes, that the consequences of them might have occasioned great disorders in the university of Bourges, if *Cujacius* had not left the field, and retired to Valence, in order to teach civil law there.

He died in 1559, without having ever married. He had great learning and an excellent judgment, but a very bad memory; so that he was obliged always to read his lectures from his notes. His *Treatise of Benefices*, which he published in 1550, rendered him suspected of heresy; and it was inserted in the *Index Expurgatorius* at Rome. Baudouin treated him as a prevaricator and dissembler, and reproached him with being a plagiarist from Calvin, in his book relating to the priesthood: which reproach Baudouin is supposed to have cast upon him, in order to expose him to the rage of persecutors. Duaren was highly incensed at it, and complained by letter, as well as by word of mouth, to Calvin, who pacified him.

A collection of his works was made in his life-time, and printed at Lyons in 1554: but, after his death, another edition more complete was published in 1579, under the inspec-

* He calculated the nativity of one of his sons, but the prognostic founded on it, and its subsequent verification, are fictions of Corinna.

tion of Nicholas Cifner, who had been his scholar, and was afterwards professor of civil law at Heidelberg, which contains: 1. *Commentaria in varios Titulos Digesti et Codicis.* 2. *Disputationum Anniversariarum, Libri duo.* 3. *De Jure Accrescendi, Libri duo.* 4. *De Ratione docendi discipulorum Juris.* 5. *De Jurisdictione et Imperio.* 6. *Apologia adversus Eugularium Baronem.* 7. *De Plagiariis.* This Bayle calls "a curious treatise, but too short for so copious a subject." 8. *In Consuetudines Fendorum Commentarius.* 9. *De sacris Ecclesiæ Ministeriis ac Beneficiis.* 10. *Pro Libertate Ecclesiæ Gallicæ adversus Artes Romanas Defensio.* 11. *Epistola ad Sebasti. DUBLIN (*Encycl.*) In the beginning of the year 1797, an act of parliament was passed in Ireland, for the regulation of the Dublin house of industry. It had been under the direction of the corporation for the relief of the poor in Dublin; consisting of the principal officers of state, the aldermen of the city, and others, in all about 200 governors; a number, which promised very little regular attention, and afforded no personal responsibility. Count Rumford had, in May 1796, visited Dublin, at the instance of Mr. Secretary Pelham; and had conferred with him the necessary arrangements, for the improvement of the establishment, and for the correction of the existing defects. By the new act (which was brought into the Irish house of commons by Mr. Pelham in the ensuing session) the conduct of the institution was confided to seven acting governors, or directors, to be annually elected by, and out of, the members of the corporation.

The average number of the persons then in the house exceeded 1700. These were formed into classes, according to their ages, conduct, abilities, and other peculiar circumstances; and from among them was selected a *class of merit* (lodged and fed apart from the others) consisting of those who had distinguished themselves by superior industry, by moral and regular conduct, and by obedience to the rules of the house.

Each class was placed under the immediate superintendence of one of the directors; who engaged to pay daily attention to it, and to make his report regularly to the board: so that a register was obtained of the circumstances and conduct of all the persons in the house; a line was drawn between the idle vagrant and the distressed manufacturer; their wants were accurately known, and immediately attended to.—For the religious duties of the poor, there were two chaplains on the establishment; one a Protestant, the other a Roman-catholic.

Many persons had originally entered the house with an expectation of receiving better and more food, *without any labour*, than what they could have obtained by *their industry* out of the house. In order to diminish the effect of this potent encouragement to idleness (the inconvenience of which is not confined to the city of Dublin exclusively) the directors resorted to the principle, which had been acted upon at Hamburg,

and which has been stated in a preceding Report. They reduced the *ordinary* diet of the house below what any industrious labourer, out of the house, could obtain by his earnings at the lowest rate of wages: at the same time, in order that the poor persons upon the establishment might *enjoy* the profits of their work, in the manner most pleasant and most advantageous to themselves, the directors opened a shop in the house; where every article of reasonable luxury, and innocent gratification, is sold at prime cost, upon a plan similar to that of the shop established at Mongewell by the Bishop of Durham; an account whereof is given in another place.

The expence of the diet of the house had been very great. This had been occasioned, partly by the kind of food with which they had been supplied, and partly by the peculation of the persons employed. In order to correct the latter, the following mode of distribution has been adopted: the head porter, every morning early, returns to the secretary the number to be provided with food for the day. The secretary then calculates the quantity necessary to be issued from the stores; and the several officers acknowledge the receipt in pass books, which being compared once a week with the steward's store book, the balance is ascertained.

The directors also adopted a cheaper and more nutritive system of diet. An ox-head stew, and soups prepared upon Count Rumford's principle (*see SOUP*), have been distributed to the poor: and the practice which existed among them, of exchanging their bread for whiskey, has been put an end to; the bread being now mixed with the soup, before the distribution.—The improvement in the health of the poor, in consequence of the new system, has been almost commensurate to the increased economy of the house: the expence of diet for the half-year from Midsummer 1797 (when the new regulations took place), being very little more than half, and the proportionate mortality in the house less than three-fifths, of what they had been in the preceding half year.

In promoting the health and the economy of the house, the directors have also had the benefit of Count Rumford's assistance. His double boilers, with close covers, have been put up under his direction. He has invented, and constructed in one of their lumber rooms, a *perpetual oven*, which would be very useful in all our public establishments. It occupies a circular space, about 7 feet in diameter, in the centre of the room; and contains six cells for baking bread, or dressing food, all heated by one small fire, and ready in succession (or at the same time if wanted) for baking or for any operation of cookery.

What Count Rumford has done for warming and ventilating their larger rooms, is very deserving of imitation. There are two fire-places, one in the office of the master of the work, the other in the hall of merit; with flues extending horizontally, at the height of five feet from the floor, to a chimney in the centre. These communicate a sufficient and equable degree of heat, through the two great dining halls. Two of Count Rumford's *louvres* * carry off the vitiated air; and a fresh supply of *atmospheric* air is ob-

* These *louvres* ought to be used, not only in houses of industry, manufactories, and gaols, but in all crowded rooms, where those who have the misfortune to be confined in them, suffer extremely both in health and spirits, by exhausted and corrupted air. They are made on a very simple construction; and they not only act very powerfully, and are easily regulated, but their action may be totally suspended at pleasure. They are so constructed, that every wind that blows, acts at the same time, both by *compression* and by *exhaustion*, to ventilate the apartments with which they communicate. Part of those put up by Count Rumford at Dublin, were intended for a long garret over the hall. This garret, which was fitted up as a dormitory for some of their most industrious children, was so very low, that those who were destined to sleep in it, would certainly have felt the want of fresh air, had not some extraordinary means been used to procure a supply of it. The necessary ventilation is obtained by means of three six-sided vertical wooden tubes, which, passing through the roof of the building, project 3 or 4 feet above it, and communicate with the room below. By two of these tubes, placed at the two ends of the dormitory, and terminating in two long wooden

tained by small apertures, which are made at the bottom of the side walls, and covered with perforated boxes.

Difficulties have always existed with regard to the mode of supplying the necessitous poor with clothing. Where it is given *gratuitously and indiscriminately*, it is neither sufficiently valued, nor properly preserved; it is often commuted for spirituous liquors, and it *always* has a tendency to relax industry. By the regulations adopted at Dublin, the clothing of all persons capable of labour, is to be supplied solely from their own exertions. At the same time, instead of *one-sixth*, their former allowance, they have *two-thirds of all their earnings*; the remaining third being deemed nearly sufficient to defray the expense of machinery and superintendence. As an additional encouragement, they whose clothing is furnished by their own industry, are permitted to have one day in the week to go out and visit their friends; the indulgence being, in their case, not liable to the general objection, that, while they were out of the house, they often made away with part of their clothes.

The labour of the directors of the house of industry at Dublin, has been extremely diminished by a proper distribution of attention, of authority, and of responsibility; by the power being placed in very few hands, and by each director having the *whole merit of his own personal exertions*. But, where there is much misery * and depravity to correct, which appears to have been the case with the paupers on this establishment, it is requisite that prudence, activity, firmness, and perseverance, should all be employed, as they have been in this instance, much to the honour of the directors.

It must give great satisfaction to every one, who is aware that religion, morality, industry, and prudence, have, like the arts, a common bond of union, and produce their full effects in those instances only where they act in concert, to observe, that in this establishment, where there are so many Roman-catholics, objects of its protection, there is a priest of their own persuasion, provided for their religious improvement.—No reformation of the poor can be *completely* brought about, without the aid of religion.—This must be the *foundation* of every thing effectual, to be done for them—the *superstructure* should be aid, encouragement, and distinction.

In respect also of that superstructure, the arrangement in the Dublin house of industry is wise and judicious. The aid and encouragements given to industry, in this instance, have exceeded those of any similar establishment. But the peculiar feature of the institution, is the *distinction of classes*, particu-

larly that of the separate and favoured *class of merit*;—which must, gradually, become an object of ambition to every person in the house, to the amendment even of the most idle, and the most profligate.

The regulation which fixes (as at Hamburg) their standard of the common diet, below what may be obtained by the earnings of the industrious labourer out of the house, is deserving of observation, and of imitation in England. Much injury is done to the spirit and feelings of the English cottager, not merely by the wanton and ostentatious profuseness of the rich and vain, but also by the gross and offensive waste that is apparent in most of our workhouses and public charities.

It is no small merit in the directors (we wish we could offer our public establishments in England the same tribute of commendation), that they have readily adopted the improvements suggested by Count Rumford; and, by attention and proper management, have given them their due success. They have taken the full benefit of his assistance in respect of the diet of the house—of the boilers and oven which he has constructed for them—and of the economical mode which he has suggested of warming and purifying the air of their larger rooms. The introduction of his improvements into *all our public establishments*, particularly those improvements which contribute to temper and sweeten the air in crowded buildings, would be an important and national benefit. Indeed, we are unreasonable enough to wish, that the other classes of society in England, instead of being kept from the habitations of the poor by their want of cleanliness, and by the dread of offensive or contagious air, would exert themselves effectually in assisting and enabling them to correct the evil.

It must be a subject of real satisfaction to every well-wisher to his country, that, in the course of the preceding spring, a society has been formed at Dublin, *for promoting the comforts of the poor*; the President of which is the Marquis Cornwallis, the Lord Lieutenant of that kingdom; the six Vice-presidents, the Chancellor, the Speaker, and four other persons of the first rank; and the 34 members of the committee, some of the most respectable characters in that country.

In their account of the plan and regulations of the society, they state, that some individuals having observed with pleasure the progress of a society, instituted in England in the year 1796, "*for bettering the condition, and increasing the comforts of the poor*," were encouraged by their success to form themselves into a society, founded upon similar principles, to be

boxes, which are bored full of small holes, and rest on the floor of the room, fresh atmospheric air from without is *forced* into the room, while the foul air is carried off by means of the third tube, placed over the middle of the room, with its lower opening even with the ceiling. This tube is furnished with a register, or damper. The whole of this machinery is made of wood; and as no part of it is moveable, except the register, it is not expensive, nor liable to be put out of order.

* It is hardly possible to enter into a detail of the late improvements in the Dublin house of industry, without adverting to the general situation of the lower class of our fellow-subjects in Ireland. Much, indeed, has been recently done by individuals, in particular districts; by Mr. Pelham, in encouraging the industry and good habits of the poor in the vicinity of Dublin, and in introducing a friendly communication between them and their more opulent neighbours; and by the Speaker, Mr. Foster, in the promotion of agriculture, manufactures, and commerce. There are of the highest order of national improvement; and afford a fair prospect, that what is so well begun, will be pursued with that energy and perseverance, which the importance of the subject demands.—The disadvantages of many of the poor in Ireland, originate in want of education, in a total ignorance of the comforts of life, and a consequent indifference about them. With such persons, the spur that should impel them to action, and the bond that should connect them with society, are wanting. Having neither property, nor the means of preserving it—consisting in the mildness of the climate, in the fertility of the soil, and in the facility of obtaining those mere necessities of existence with which they are acquainted—what security can their country possess for conduct, what impulse to industry and exertion?—The necessary remedies—the introduction of a proper system of education, of habits of cleanliness, and of a taste for the comforts of life, as applied to food, habitation, and clothes;—the extending of the power of acquiring property, and the means of preserving it;—the promoting of more connection, and more intercourse of kindness and benevolence, between the different ranks of life—these are measures, which require *superior talents and industry* to arrange and conduct;—measures, essential, not merely to the prosperity of Ireland, but, at the present crisis, to the security of Great Britain.

denominated "the society for promoting the comforts of the poor."—That the general object of the society (being the same as the declared object of the English society) is to collect and circulate such useful and practical information, derived from experience, respecting the circumstances and situation of the poor, and the most effectual means of meliorating their condition, as may induce and enable all well-disposed persons to unite in the promotion of measures so important to the happiness and welfare of the community at large.—That they are determined ever to keep in view this principle—"that the best relief the poor can receive, is from themselves; and that the most effectual method of improving their condition, is by the encouragement of *industry, prudence, and cleanliness*;" and they trust that the local experience of humane individuals, whether employed for the encouragement of industry and increase of comfort, for the prevention and relief of distress, or for the general improvement of the morals and condition of the lower classes, being thus collected, and afterwards diffused over the kingdom at large, will animate and instruct the nation in the pursuit of these important objects.

Their regulations do not materially differ from those of the English Society.—See SOCIETY, in this SUPPLEMENT.

It cannot but be flattering to the latter, to see another institution, professedly originating out of the success attending its progress, founded in a neighbouring island, on the same principles, and under the highest patronage.

Nothing can be more honourable to this country, than the disposition to generally prevalent amongst individuals in the higher orders of society, to exert themselves for the benefit of the poorer classes of their fellow-subjects; and nothing can be of greater importance, than to give this disposition a proper direction, that the efforts of benevolence may not be defeated, by a misapplication of its assistance.

The knowledge required for this purpose must be the result of experience, to which nothing can more certainly lead, than investigations how the comforts of the poor may be best promoted; not by relaxing their industry, or weakening their habits of frugality, but by strengthening and increasing the motives to both; for "if the manner in which relief is given, is not a spur to industry, it becomes, in effect, a premium to sloth and profligacy."

The reports of the London society prove, that the object, though difficult of attainment, is not impracticable:—that the means for this purpose may be so adapted, as to relieve the poor, and excite their industry; to increase their means of subsistence, and yet encourage economy, and render the effects of liberality subservient to the best of moral uses, that of promoting good habits.

Every new institution having the same objects in view, must in its progress augment the general mass of experimental information; and whilst we anticipate with pleasure the prospect of our own gains in this respect, from the establishment of the Dublin society, we cannot but participate the satisfaction which the poor of that country must feel, from the public demonstration which this establishment affords, of a general attention to their interests, and an anxiety to promote their comforts; nor could any more effectual means be devised to conciliate their affections.

The comparative experience, which will be found in the reports of similar societies in different countries, must lead to important and beneficial conclusions. The same modes of relieving the industrious poor, are not adapted to all states and situations, although the principle which should govern the application of them cannot be varied. Much has been done, and more may be successfully performed by the efforts of individuals in England, in correcting the prejudicial effects of the poor laws, workhouses, mendicity, &c. and in Ireland the

field appears to be equally extensive for the exertions of individual benevolence.

Amongst other recent improvements calculated to encourage industry and promote good habits among the poor in this city, is a society of farmers, who confer rewards on those who exert themselves in the labours of agriculture.

At a quarterly-meeting of the farmers' society, established by Mr. Pelham, for the district of Castleknock, Blanchertown, and Portertown, near Dublin, held in March 1798, the following premiums were offered to labourers and their families within the district.

Premiums proposed by the Farmers' Society for the Union of Castleknock, for the year 1798.

- | | £. | s. | d. |
|---|----|----|----|
| 1. To the best ploughman with oxen - - - | 2 | 2 | 0 |
| 2. To ditto, with horses - - - | 2 | 2 | 0 |
| The qualifications necessary to gain the above premiums, to be settled by a committee appointed for that purpose. | | | |
| 3. To the labourer who shall appear to have brought up the greatest number of legitimate children in the habits of industry to the age of twelve years - - - | 2 | 2 | 0 |
| 4. To the labourer, for the next greatest number - - - | 1 | 1 | 6 |
| 5. To the labourer, for the third greatest number - - - | 1 | 1 | 0 |
| 6. To the labourer in farming, who shall have lived the greatest number of years (not less than five) in the same service, and behaved with sobriety, honesty, and industry, during that time, and who shall produce a satisfactory certificate from his master, of such continued good behaviour - - - | 2 | 2 | 0 |
| 7. To the dairy-maid, who shall have lived the greatest number of years under the above conditions - - - | 1 | 1 | 0 |
| 8. To the wife or widow of a labourer or manufacturer, who shall have done the greatest number of days' work in husbandry - - - | 1 | 1 | 0 |
| 9. To ditto, for the next greatest number - - - | 0 | 10 | 6 |
| The above Premiums not to exceed 3d. a-day for the first, nor 2d. a-day for the second. | | | |
| 10. To six labourers, who shall obtain from their respective clergymen and employers, certificates of their being most attentive to religious duties, the most sober, honest, and industrious, and in every respect the best-conducted labourers within the union - - - | 3 | 3 | 0 |
| 11. To six boys and six girls, who shall be returned from the school of Castleknock, Blanchertown, and Portertown, as being the most attentive to learning, and the best-behaved children of said schools - - - | 3 | 3 | 0 |
| The certificates to be signed by the masters, and countersigned by their respective clergymen; these premiums to be given in books or clothes. | | | |
| 12. Resolved, that we will every year give the sum of one guinea, to purchase useful tracts for each of the three schools in the union - - - | 3 | 3 | 0 |
| The tracts to be chosen by a committee appointed for the purpose: an examination to be held, and premiums given to such of the scholars as shall give the best account of said tracts. | | | |
| 13. To three boys and three girls, under the age of twelve years, who shall appear to the society by certificates from their employers, to have earned the most money in the year in country business - - - | 3 | 3 | 0 |
| 14. To the same number of boys and girls, from twelve to sixteen years old, under the same conditions - - - | 3 | 3 | 0 |
| The first premium not to exceed 2d. nor the other 3d. per day. | | | |

15. To three labourers, or widows of labourers, who shall be returned, by inspectors appointed for the purpose, as having kept their children, cabbins, and gardens, in the neatest, cleanliest, and most decent order (gentlemen's lodge excepted), one guinea for each division of the union

16. To the wife or widow of a labourer, who shall (with the assistance of her children, under the age of sixteen years) have spun the greatest quantity of linen or woollen yarn, and prepared the same for the loom, within the year

17. To ditto, for the next greatest quantity

18. To ditto, for the third greatest quantity

19. To the wife or widow of a labourer, who with the assistance of her children under sixteen years of age, shall have knit the greatest number of pairs of stockings within the year

20. To ditto, for the next greatest number

21. To ditto for the third greatest number

The quantity of yarn, and number of pairs of stockings, to be certified on oath.

22. To three labourers, who shall be returned by judges appointed for the purpose, as being the most expert and handy in the different works of husbandry, viz. ditching, draining, thatching, plashing hedges, &c. (ploughing excepted)

Total of premiums

The premiums for ploughing, ditching, draining, and for handy labourers, &c. to be determined by a committee appointed for that purpose.

Premiums No. 1, 2, 3, 4, 5, 6, 7, and 22, to be determined the last Monday in June, 1798: all claims for said premiums to be sent in to the secretary, on or before the 11th of June, 1798. The other premiums require a year for their determination; which year begins the 1st of April, 1798, and ends the 1st of April, 1799. All claims for said premiums to be sent in to the secretary, on or before the 1st of April, 1799, and to be determined at the quarterly meeting of the society, on the last Monday in June following.

The beneficial tendency of the measures adopted by this society, for encouraging the virtues of the poor, is so obvious, and the expediency and utility of them so apparent, that it is difficult to suggest any observation on the subject, which the good sense and intelligence of the reader will not have already anticipated. No accumulation of criminal law, no penalties on imprudence and idleness, no repairs of the flocks and the cage, no additions to our goals and houses of correction—in short, no severity of punishment, though it may in some degree deter from crimes, can ever produce, among the great mass of the people, any increase of energy and good habits, which will bear a comparison with that which must necessarily spring from the judicious and benevolent encouragement afforded to their poor neighbours, in this instance, by the fifth gentlemen and farmers.

There is so little trouble, expence, or difficulty in the measure, that we may venture to call upon the inhabitants of our different parishes and districts, as they regard either their own interest or the welfare of others, to imitate this useful example; and generally to adopt a plan, the good effects of which must be unquestionable. There are several societies in England, which have done very essential service to their neighbourhoods, by embracing part of these objects: but the framer of these resolutions has contrived, in this instance, to awaken at once all orders and all ages of the labouring poor in his neighbourhood; and, by the kindest and most acceptable

encouragement to action, to stimulate them all to progress and perseverance in those courses of life, which will prove most useful and most beneficial to themselves and their country.

DUCHAL (James), a learned minister among the Dissenters, was born in Ireland in 1697. He had his early education under the direction of an uncle; his preparatory studies were greatly assisted by the well-known and justly-admired Mr. Abernethy; and he finished his course of study at the university of Glasgow: which, in testimony of his merit, conferred on him the degree of D.D. He resided for ten or eleven years at Cambridge, as the pastor of a small congregation there; where he enjoyed his beloved retirement, the advantage of books, and of learned conversation, which he improved with the greatest diligence. On Mr. Abernethy's removal from Antrim, he succeeded him in that place; and, on the death of the said worthy person, was chosen to be minister to the Protestant Dissenting congregation of Woodstreet, Dublin. In this situation he continued to his death, which happened in 1761.

It is very remarkable, and worth recording, that, during his residence here, when he was in the decline of life, of a valetudinary habit, and had frequent avocations in the way of his profession, he composed and wrote sermons to an amount almost beyond belief: more, it appears on the best computation, than 700. From this mass, a collection was taken after his death, and published in 3 vols, 8vo: in 1764. They are mostly on new and uncommon subjects; and a vein of strong manly sense and rational piety runs through the whole.

During his life, he published a volume of excellent discourses on the presumptive arguments in favour of the Christian religion: and many occasional tracts both in England and Ireland.

DUCHAT (Jacob le), a Frenchman, distinguished among the literati, was born at Metz in 1658. He was trained to the law, and followed the bar, till the Reformed were driven out of France, by the revocation of the edict of Nantz. In 1701 he settled at Berlin; became a member of the Academy of Sciences; and died there in 1735. He was regarded as a very learned person, yet is distinguished as an editor, rather than an author. He had, it seems, a great taste for the ancient French writers; and gave new editions of the Menippean Satires, of the Works of Rabelais, of the Apologie for Herodotus, by Henry Stephens, &c. all accompanied with remarks of his own. He held a correspondence with Bayle, whom he furnished with many particulars for his Dictionary. After his death was published a "Ducatiana," at Amsterdam, in 1738, 2 vols. 12mo.

DUCK (Arthur), a civilian, was born in Devonshire in 1580, of a considerable family; and at fifteen years of age became a student at Exeter College in Oxford, where he took a degree in arts in 1599. From thence he removed to Hart-hall, and afterwards was elected fellow of All-Souls; but his genius leading him to the study of the civil law, he took his other degrees in that faculty. He travelled into France, Italy, and Germany; and, after his return, was made chancellor of the diocese of Bath and Wells. He was afterwards made chancellor of London, and at length master of the Requests; but the confusions, which were then beginning, probably hindered him from rising higher. In 1640 he was elected burgess for Minehead in Somersetshire, and soon after siding with King Charles in the time of the rebellion, became a great sufferer in the fortunes of his family. In 1648 he was sent for by his majesty to Newport in the Isle of Wight, to be assisting in his treaty with the commissioners from the parliament; but, that treaty taking no effect, he retired to his habitation at Chiswick near London, where he died, in 1649. He was an excellent civilian, a tolerable poet, especially

in his younger days, and very well versed in history, ecclesiastical, as well civil. He left behind him "Vita Henrici Chichele, &c." and "De Ufu & Authoritate Juris Civilis Romanorum in Dominiis Principum Christianorum:" a very useful and entertaining work, which has been printed several times at home and abroad. He was greatly assisted in this work by the learned Dr. Gerard Langbaine.

DUCK CREEK, a town of the state of Delaware, which carries on a considerable trade with Philadelphia. It is 12 miles N. W. of Dover.

DUDLEY (Robert), baron of Denbigh, and earl of Leicester, son to John duke of Northumberland, and brother to Ambrose earl of Warwick, before mentioned, was born about 1532; and coming early into the service and favour of King Edward, was knighted in his youth. June 1550 he espoused Amy, daughter of Sir John Robbarts, at Sheen in Surrey, the king honouring their nuptials with his presence; and was immediately advanced to considerable offices at court. In the first year of Mary, he fell into the same misfortunes with the rest of his family; was imprisoned, tried, and condemned; but pardoned for life, and set at liberty in October 1554. On the accession of Elizabeth, he was immediately entertained at court as a principal favourite: he was made master of the horse, installed knight of the Garter, and sworn of the privy-council, in a very short time. He obtained moreover prodigious grants, one after another, from the crown: and all things gave way to his ambition, influence, and policy. In his attendance upon the queen to Cambridge, the highest reverence was paid him: he was lodged in Trinity College, consulted in all things, requests made to the queen through him; and, August 10, 1564, he on his knees entreated the queen to speak to the university in Latin, which he accordingly did. At court, however, Thomas earl of Suffex shewed himself averse to his counsels, and strongly promoted the overture of a marriage between the queen and the Archduke Charles of Austria; as much more worthy of such a princess, than any subject of her own, let his qualities be what they would. This was resented by Dudley, who insinuated, that foreign alliances were always fatal; that her sister Mary never knew an easy minute after her marriage with Philip: that her majesty ought to consider, she was herself descended of such a marriage as by those lofty notions was decreed: so that she could not condemn an alliance with the nobility of England, but must at the same time reflect on her father's choice, and her mother's family. This dispute occasioned a violent rupture between the two lords, which the queen took into her hands, and composed; but without the least diminution of Dudley's ascendancy, who still continued to solicit and obtain new grants and offices for himself and his dependants, who were so numerous, and made so great a figure, that he was styled by the common people "The Heart of the Court."

To give some colour to these marks of royal indulgence, which, indeed, seemed to require an offensive motive, the queen proposed him as a suitor to Mary queen of Scots; promising to that princess all the advantages she could expect or desire, either for herself or her subjects, in case she consented to the match. The sincerity of this was suspected at the time, when the deepest politicians believed that, if the Queen of Scotland had complied, it would have served only to countenance the preferring him to his sovereign's bed. The Queen of Scots rejected the proposal in a manner that, some have thought, proved as fatal to her, as it had done to his own lady, who was supposed to be sacrificed to his ambition of marrying a queen. The death of this unfortunate personage happened September 8, 1560, at a very unlucky juncture for his reputation;

because the world at that time conceived it might be much for his convenience to be without a wife, this island having then two queens, young, and without husbands. The manner too of this poor lady's death, which was by a fall from a high station, filled the world with great consternation.

Sept. 1564, the queen created him baron of Denbigh, and, the day after, earl of Leicester, with all the pomp and ceremony imaginable; and, before the close of the year, he was made chancellor of Oxford, as he had been some time before high-steward of Cambridge. His great influence in the court of England was not only known at home, but abroad, which induced the French king, Charles IX. to send him the order of St. Michael, then the most honourable in France; and he was installed with great solemnity in 1565. About 1572, it is supposed that the earl married Douglas, baroness-dowager of Sheffield; which, however, was managed with such privacy, that it did not come to the queen's ears, though a great deal of secret history was published, even in those days, concerning the adventures of this unfortunate lady. We call her unfortunate, because, though the earl had actually married her, and there were legal proofs of it, yet he never would own her as his wife. Some of the wits in Queen Elizabeth's court, after the earl's public marriage with the Countess-dowager of Essex, styled these two ladies, Leicester's two Testaments; calling Lady Douglas the Old, and Lady Essex the New Testament. The earl, in order to stifle this affair, proposed every thing he could think of to Lady Douglas Sheffield, to make her desist from her pretensions: but, finding her obstinate, and resolved not to comply with his proposals, he attempted to take her off by poison. It is however beyond all doubt, that the earl had by her a son, Sir Robert Dudley, of whom we have spoken elsewhere, and to whom, by the name of his *bastard son*, he left the bulk of his fortune; and also a daughter.

In 1576 happened the death of Walter earl of Essex, which drew upon Lord Leicester many suspicions, especially after his marriage with the Countess of Essex was declared; as it was two years after. For, in 1578, when the Duke of Anjou pressed the match that had been proposed between himself and the queen, his agent, believing Lord Leicester to be the greatest bar to the duke's pretensions; informed the queen of his marriage with Lady Essex; upon which her majesty was so enraged, that, as Camden relates, he commanded him not to stir from the castle of Greenwich, and would have committed him to the Tower, if she had not been dissuaded from it by the Earl of Suffex. Lord Leicester being now in the very height of power and influence, many attempts were made upon his character, in order to take him down: and, in 1584, came out a most virulent book against him, commonly called Leicester's Commonwealth. The drift of it was to shew, that the English constitution was subverted, and a new form imperceptibly introduced, to which no name could be so properly given, as that of a Leicesterian Commonwealth. To make this pass the better, the earl was represented as an atheist in point of religion, a secret traitor to the queen, an oppressor of her people, an inveterate enemy to the nobility, a complete monster with regard to ambition, cruelty, and lust; and not only so, but as having thrown all offices of trust into the hands of his creatures, and usurped all the power of the kingdom. The queen, however, did not fail to countenance and protect her favourite; and, to remove as much as possible the impression this bitter performance was sure to make upon the vulgar, caused letters to be issued from the privy-council, in which all the facts contained therein were declared to be absolutely false, not only to the knowledge of those who signed them, but also of the queen herself. Nevertheless, this book was universally read, and the contents of it generally received for true; and

the great secrecy with which it was written, printed, and published, induced a suspicion, that some very able heads were concerned either in drawing it up, or at least in furnishing the materials. It is not well known what the original title of it was, but supposed to be *A Dialogue between a Scholar, a Gentleman, and a Lawyer*; though it was afterwards called *Leicester's Commonwealth*. It has been several times reprinted, particularly in 1600, 8vo. in 1631, 8vo. the running-title being *A Letter of State to a Scholar of Cambridge*; in 1641, 4to. and 8vo. with the addition of *Leicester's Ghost*; and again in 1706, 8vo. under the title of *Secret Memoirs of Robert Dudley, Earl of Leicester*, with a preface by Dr. Drake, who pretended it to be printed from an old manuscript. The design of reprinting it in 1641, was, to give an ill impression of the government of Charles I. and the like was supposed to be the design of Dr. Drake in his publication. Indeed, it may be considered as a standing check upon all overgrown ministers, and governments by faction.

Dec. 1585, Lord Leicester embarked for the Protestant Low-countries, whither he arrived in quality of governor. At this time the affairs of those countries were in a perplexed situation; and the States thought that nothing could contribute so much to their recovery, as prevailing upon Queen Elizabeth to send over some person of great distinction, whom they might set at the head of their concerns, civil and military: which proposition, says Camden, so much flattered the ambition of this potent earl, that he willingly consented to pass the seas upon this occasion, as being well assured of most ample powers. Before his departure, the queen admonished him to have a special regard to her honour, and to attempt nothing inconsistent with the great employment to which he was advanced: nevertheless, she was so displeased with some proceedings of his and the States, that the year after the sent over very severe letters to them, which drew explanations from the former, and deep submissions from the latter. He returned to England, Nov. 1585; and, notwithstanding what was said, was well received by the queen. What contributed to make her majesty forget his offence in the Low-countries, was the pleasure of having him near her, when she wanted his counsel extremely; for now the affair of Mary queen of Scots was upon the carpet, and the point was, how to have her taken off with the least discredit to the queen. The earl thought it best to have her poisoned; but that scheme was not found practicable, so that they were obliged to have recourse to violence. The earl set out again for the Low-countries in June 1587; but, great discontents arising on all sides, was recalled in November. Camden relates, that on his return, finding an accusation preparing against him for mal-administration there, and that he was summoned to appear before the council, he privately implored the queen's protection, and besought her "not to receive him with disgrace upon his return, whom at his first departure she had sent out with honour; nor bring down alive to the grave, whom her former goodness had raised from the dust." These expressions of humility and sorrow wrought to far upon her, that he was admitted into her former grace and favour.

In 1588, when the nation was alarmed with the apprehensions of the Spanish armada, Lord Leicester was made lieutenant-general, under the queen, of the army assembled at Tilbury. This noble personage stood high in the favour of his mistress to the last: for he died this year, Sept. 4, at his house at Cornbury in Oxfordshire, while he was upon the road to Kenilworth. His corpse was removed to Warwick, and buried there in a magnificent manner. He is said to have inherited the parts of his father. His ambition was great, but his abilities seem to have been greater. He was a finished courtier in

every respect; and managed his affairs so nicely, that his influence and power became almost incredible. He had a competent knowledge of the Latin tongue, and was thoroughly versed in the French and Italian.

DUDLEY, a town in Worcestershire, with a market on Saturday, and a great manufacture of nails and other ironwares. There is a church at each end of the longest street. It is 10 miles N. W. of Birmingham and 120 of London. Long. 2. o. W. Lat. 52. 33. N.

DUFFET (Thomas). This author was a milliner in the New-Exchange; but, his genius leading him to dramatic poetry, he wrote several pieces for the stage, which at first met with good success, but afterwards sunk into contempt and oblivion. Traveltie and burlesque will ever create a laugh; but, however intended, can never do any essential hurt to performances of real worth; nor could *The Mock Tempest*, *Psyche*, or *Empress of Morocco*, lessen, in the opinion of the judicious, the value of the originals on which they are founded. The pieces Mr. Duffet has left behind him, the best of which were those which met with the worst success, are fix in number. They are enumerated in the *Biographia Dramatica*.

DUGARD (William), an eminent school-master and learned man, was the son of Henry Dugard, a clergyman, and born at Bromsgrove in Worcestershire in 1606. He was instructed in classical learning at a school in Worcester; and from thence sent, in 1622, to Sidney College, Cambridge. In 1626 he took the degree of B.A. and that of M.A. in 1630. Soon after he was appointed master of Stamford-school in Lincolnshire; from whence, in 1637, he was elected master of the free-school in Colchester. He resigned the care of this school Jan. 1642-3; and, May 1644, was chosen head-master of Merchant-Taylors' school in London. This school flourished exceedingly under his influence and management; but for shewing, as was thought, too great an affection to the royal cause, and especially for being concerned in printing Salmasius's defence of Charles I. he was deprived of it Feb. 1649-50, and imprisoned in Newgate; his wife and six children turned out of doors; and a printing-office, which he valued at a thousand pounds, seized. That he was very well affected to Charles I. and to the royal interest, appears from a curious register he kept of his school, which is still extant in Sion-College library, wherein are entered two Greek verses, on the beheading of that monarch, to this effect: "Charles, the best of kings, is fallen by the hands of cruel and wicked men, a martyr for the laws of God and of his country." There are also two more Greek verses on the burial of Oliver Cromwell's mother in Westminster Abbey to this effect: "Here lieth the mother of a cursed son, who has been the ruin of two kings, and of three kingdoms." However, it was not for these verses that he was dismissed the school, but for being concerned in printing Salmasius's book.

Being soon released from this confinement, he opened, April 1650, a private school on Peter's-hill, London; but, in September, was restored to his former station, by means of the same council of state who had caused him to be removed. There he continued with great success and credit, till about 1661; when he was dismissed for breaking some orders of the Merchant-Taylors, though he had been publicly warned and admonished of it before. He presented a remonstrance to them upon that occasion, but to no purpose; whereupon he opened a private school in Coleman-street, July 1661, and, by March following, had gathered an hundred and ninety-three scholars: so great was his reputation, and the fame of his abilities. He lived a very little while after, dying in 1662. He gave by will several books to Sion-College library. He published some few pieces for the use of his schools; as,

1. *Lexicon Græci Testamenti Alphabeticum*; una cum Explicatione Grammatica Vocum singularum, in usum Thronum, Neemon Concordantiâ singulis dictionibus appositâ, in usum Theologiæ Candidatorum, 1660. 2. *Rhetorices compendium*, 8vo. 3. *Luciani Samosatensis dialogorum selectiorum libri duo*. A. G. Dugard recogniti, et variis collatis exemplaribus, multo castigatius quam antea editi. Cum interpretatione Latina, multis in locis emendata, et ad calcem adjecta, 8vo. 4. A Greek Grammar.

DUGUET (James-Joseph), a French writer, and author of almost twenty works in the French language, was born in 1649, and became a priest of the Oratory. In 1685 he quitted the Oratory, and went to Brussels to his great friend Arnauld: but, the air of this place not agreeing with him, he returned the same year to France, and lived a very retired life in the midst of Paris. He afterwards lived with president Le Menars. His opposition to the Bull Unigenitus, and his attachment to the doctrine of his friend Quesnel, occasioned him much trouble, by obliging him often to shift his quarters. He was in Holland, at Troyes, and Paris; but there was a sweetness and moderation in his make, which kept him always tranquil. He died at Paris in 1733. All his works are upon subjects of theology and piety, except *De l'Education d'un Prince*; first printed in 4to. and afterwards in 4 vols. 12mo, with his life prefixed by Abbé Goujet. The style of Duguet is clear, pure, and elegant, but too diffuse.

DUINS, or **DOINO**, a sea-port of Germany, in the duchy of Carniola, eight miles N. W. of Trieste. Long. 13. 46. E. Lat. 45. 55. N.

DUISBURGH, a town of Westphalia, in the duchy of Cleves, with a university; seated on the Roer, near the Rhine, 12 miles N. of Dusseldorf. Long. 6. 50. E. Lat. 51. 22. N.

DUITZ, or **DURTZ**, a town of Westphalia, on the E. side of the Rhine, opposite Cologne. It is chiefly inhabited by Jews, who are not allowed to dwell at Cologne, or even enter that city without permission.

DUKE (Richard), was bred at Westminster and Cambridge, and was some time tutor to the Duke of Richmond. He appears from his writings to have been well qualified for poetical compositions: and, conscious of this when he left the university, he enlisted himself among the wits. He was the familiar friend of Otway, and was engaged, among other popular names, in the translations of Ovid and Juvenal. In his Review, though unfinished, are some vigorous lines. With the wit he seems to have shared the dissoluteness of the times; for some of his compositions he must have reviewed himself with detestation in his later days, when he published those sermons which Featon has commended. In 1683, being then M. A. and fellow of Trinity College in Cambridge, he wrote a poem on the marriage of Lady Anne with George prince of Denmark. He took orders, and being made prebendary of Gloucester, became a proctor in convocation for the church, and chaplain to Queen Anne. In 1710 he was presented by the Bishop of Winchester to the wealthy living of Witney in Oxfordshire, which he enjoyed but a few months. Feb. 10, 1711, having returned from an entertainment, he was found dead the next morning.

DUKE OF YORK'S ISLAND, an island in the S. Pacific Ocean, discovered by commodore Byron in 1765, lying N. of the Friendly Islands. The ground was covered by land-crabs, but no other animal was seen. Long. 172. 30. W. Lat. 8. 0. S.

DUKE OF YORK'S ISLAND, an island in the S. Pacific Ocean, about 10 miles long, lying between Lord Howe's Group and the S. E. point of New Ireland. The natives go entirely naked; are stout, well made, and of a light copper colour: their hair is woolly, but they dress it with grease and

powder, and make it hang straight. Their huts are neatly made, chiefly of bamboo, and placed under the shade of coconut trees, with a fence before them, within which the plantain, banana, yam, sugar-cane, &c. are cultivated. The island is a perfect garden, and produces, besides the plants above mentioned, betel-nut, mangoes, bread-fruit, and guavas. Here are also dogs, hogs, poultry, and some spices. The nutmeg was seen by Captain Hunter, who anchored in Port Hunter Bay, in this island, in May 1791. Long. 152. 42. E. Lat. 4. 7. S.

DULAS, a village on the N. E. side of the ile of Anglesey, much frequented on account of the corn and butter trade; and for fern-alhes. Near it is a red ochrey earth, and veins of lead ore.

DULCIGNO, a town of Turkey in Europe, in Albania, on the coast of the Adriatic, with a good harbour, 15 miles S. W. of Scutari. Long. 18. 56. E. Lat. 42. 23. N.

DULDERSTADT, a town of Germany, in the duchy of Brunswick, subject to the elector of Mentz, seated on the Whipper, 15 miles E. of Gottingen, and 130 N. E. of Mentz. Long. 10. 14. E. Lat. 51. 28. N.

DULMEN, a town of Westphalia, in the bishopric of Munster, 18 miles S. W. of Munster. Long. 7. 4. W. Lat. 51. 47. N.

DULVERTON, a town in Somersetshire, with a market on Saturday, seated on a branch of the Ex, 24 miles E. of Barnstaple, and 164 W. by S. of London. Long. 3. 30. W. Lat. 51. 3. N.

DULWICH, a village in Surrey, five miles S. of London. It is famous for a college, founded by Edward Alleyn, a principal performer of Shakspeare's plays, in the reign of Elizabeth. He called it The College of God's Gift, and endowed it for a master, warden, and four fellows; three of whom were to be divines, and the fourth an organist; for six poor men and six poor women, and for 12 poor boys, to be educated by two of the fellows. The master and warden are always to be of the name of Alleyn or Allen, and to be single men.

DUMARING, a town of the island of Borneo, on the E. coast. Long. 117. 30. E. Lat. 2. 10. N.

DUMBLANE, a village in Perthshire, remarkable for a battle, called the battle of Sheriff-muir, between the Duke of Argyle and the rebel Earl of Mar, in 1715. At the upper end of the village is a ruinous cathedral. It is 30 miles N. W. of Edinburgh.

DUMFRIES, a town of Virginia, on the N. side of Quantico Creek, four miles above its entrance into the Potomac. It is 185 miles S. W. of Philadelphia. Long. 77. 26. W. Lat. 38. 36. N.

DUN, a town of France, in the department of Meuse, situate on the Meuse, 15 miles N. N. W. of Verdun.

DUNAMOND, a town of Russia, in the government of Riga. It formerly belonged to the duchy of Courland, but was taken by the Swedes in their wars with the Poles. In 1700 it was taken by the Poles, but was retaken the next year, by Charles XII. In 1710 it was taken by the czar, Peter the Great. It is situate at the mouth of the Dwina, 15 miles N. W. of Riga, and 20 N. of Mittau. Long. 23. 41. E. Lat. 57. 5. N.

DUNEBURG, a town of Livonia, on the Dwina, 90 miles S. E. of Riga. Long. 27. 0. E. Lat. 56. 8. N.

DUNGNESS, a cape on the coast of Kent, eight miles S. by W. of Romney. Long. 0. 59. E. Lat. 50. 52. N.

DUNLEER, a borough of Ireland, in the county of Louth, seven miles N. of Drogheda.

DUNLOP, sometimes pronounced **DELEP**, a village in Ayrshire, in the district of Cunningham, celebrated for rich and delicate cheese.

DUNNINGTON, a town in Lincolnshire, with a market on Saturday, 27 miles S.E. of Lincoln, and 111 N. of London. Long. 0. 7. W. Lat. 52. 55. N.

DUNNOSE, a cape on the S. side of the Isle of Wight. Long. 116. W. Lat. 50. 33. N.

DUNSE, a town in Berwickshire, situated between the forks of the rivers Blackadder and Whiteadder, in a rich and fertile country, 12 miles W. of Berwick upon Tweed. Long. 2. 5. W. Lat. 55. 46. N.

DUNSTER, a town in Somersetshire, with a market on Friday, and a harbour on the Bristol Channel. It has a castle on a steep knoll; and at one corner of the terrace is an ancient turret, supposed to be a part of the original castle, built in the time of the Conqueror. A priory stood on the N.W. side of the castle, the church of which now serves for the parish church. It is 20 miles N.W. of Taunton, and 158 W. of London. Long. 3. 41. W. Lat. 51. 13. N.

DUNWICH, a borough in Suffolk, with a market on Saturday. It is seated at the top of a loose cliff, and was formerly a bishop's see, but it is now only the remains of a town, all but two parishes being washed away by the sea. It sends two members to parliament, and is 24 miles S. of Yarmouth, and 99 N. of London. Long. 1. 55. E. Lat. 52. 21. N.

DUPORT (James), a learned English divine, and particularly skilled in the Greek language, was born in the beginning of the 17th century, and educated at Cambridge; in which university he was afterwards chosen Greek professor, and master of Magdalen College. He was preferred at length to the deanery of Peterborough, and died in 1680. He left behind him several learned works, amongst which is a Latin version of the Psalms. His *Gnomologia Homeri cum duplici parallelismo*, viz. ex sacra scriptura et gentium scriptoribus, printed at Cambridge, in 1660, shews his extensive reading, and great knowledge of the Greek tongue, and was then deemed very useful for the understanding of that poet. In 1712, when Theophrastus's Characters were published by Needham, there were printed along with them some lectures of Professor Duport upon the first sixteen characters, the fifth excepted. These lectures had lain in the library of More bishop of Ely for many years, and were at first supposed to have been drawn up by the learned Stanley, who wrote *The Lives of the Greek Philosophers*; but, upon their being communicated, they were soon known to belong to Professor Duport, and to be what he had read to his pupils at Cambridge, during the time of the great rebellion.

DUQUELLA, a province of Morocco, about 80 miles long and 60 broad, exceedingly fertile in corn and pasture.

DURAMPUR, a town of the Decan of Hindoostan, in the province of Guzarat, 45 miles S.E. of Surat, and 96 N.N.E. of Bombay. Long. 73. 14. E. Lat. 20. 32. N.

DURANCE, a river of France, which is formed near Briançon, of the rivulets Dure and Ancy, and watering Embrun, Tallard, Sisteron, Monobéque, and Cavillon, falls into the Rhone, below Avignon.

DURANGO, a populous town of Spain, in Biscay, 14 miles S.E. of Bilbao. Long. 2. 56. W. Lat. 43. 18. N.

DURANGO, a town of New Spain, in New Biscay, with a bishop's see, and good salt-works, in a fertile country. Long. 105. 0. W. Lat. 24. 50. N.

DURAZZO, a village of Albania, with a Greek archbishop's see. It has a ruined fortress, and a good harbour on the gulf of Venice, 50 miles N. of Valona. Long. 19. 19. E. Lat. 41. 54. N.

DURBY, a town of French Luxembourg, capital of a county of the same name, seated on the Ourte, 20 miles S. of Liege. Long. 5. 28. E. Lat. 53. 18. N.

DURCKEIM, a town of Germany in the palatinate of

the Rhine, 12 miles N.E. of Neustadt. Long. 8. 21. E. Lat. 49. 26. N.

DURELL (John), a celebrated divine, was born in the Isle of Jersey in 1626, and sent to Merton College in Oxford when he was fifteen years old: but when that city came to be garrisoned for Charles I. and the scholars took arms for him, he left it, at the end of two years, and went to France; where, at Caen in Normandy, he was admitted to the degree of master of arts in 1644. Afterwards he returned to his own country: but driven from thence a second time, he received episcopal ordination at Paris, in the chapel of Sir Richard Brown, his majesty's then resident in France, from the hands of Thomas bishop of Galloway, about 1651; so that, as Wood says, being a native of Jersey, ordained in France, and by a Scotch bishop, did make some doubt whether he was, what he calls himself in his books, "ecclesiæ Anglicanæ presbyter." Soon after he was invited by the Reformed Church at Caen, by an express on purpose, to come and supply the place of the famous orientalist and critic Samuel Bochart, who was then going into Sweden upon an invitation from Queen Christina; and by the Landgrave of Hesse, to preach in French at his highness's court: but it happened, that he could not accept of either of these invitations, being made chaplain to the Duke de la Force, father to the Princes of Turenne. Upon the restoration of Charles II. he returned to England; and was very instrumental in setting up the new episcopal French church at the Savoy in London. In 1663 he had a prebend conferred upon him in the church of Salisbury, another soon after in that of Windsor, and another after that in the church of Durham; being all the while chaplain in ordinary to his majesty. In 1669 he was created doctor in divinity at Oxford, by virtue of the chancellor's letters. In 1677 he was made dean of Windsor, but did not live long enough to be a bishop, though he lived some years after. All these preferments he obtained, partly through his own qualifications, being not only a good scholar, but also a perfect courtier; and partly through his interest with Charles II. to whom he was personally known both in Jersey and France. He published several things; and, among the rest, 1. *The Liturgy of the Church of England asserted*, in a sermon preached in French at the chapel of the Savoy before the French congregation. Translated into English by G. B. doctor in physic, 1662. 2. *A View of the Government and public Worship of God in the reformed Churches beyond the Seas*: wherein is shewed their conformity and agreement with the church of England, as it is established by the act of uniformity, 1662. Exceptions being made to this book by the Nonconformists, he published, 3. *A Vindication of the Church of England against the unjust and impudent Accusations of the Schismatics*, 1669. He died in 1683, and was buried at Windsor.

DUREN, a town of Germany, in the duchy of Juliers, on the river Roer, 12 miles S. of Juliers. Long. 6. 40. E. Lat. 50. 44. N.

DURSLEY, a town in Gloucestershire, with a market on Thursday, and a castle, now in ruins. It is inhabited by clothiers, and seated near the Severn, 13 miles S.W. of Gloucester, and 107 W. of London. Long. 2. 23. W. Lat. 51. 40. N.

DURTAL, a town of France, in the department of Mayne and Loire. Its chief trade is tanning. It is 16 miles N.E. of Angers.

DUSKY BAY, a bay of the island of New Zealand, in the S. Pacific Ocean. The country here is steep, and the hills near the sea-side are covered with intricate and impenetrable forests. Long. 166. 18. E. Lat. 45. 47. S.

DUTTLINGEN, a town of Suabia, with a bridge over the Danube, and a castle, seated on a mountain. It belongs to

the Duke of Wirtemberg, and is 33 miles N.W. of Constance. Long. 9. 2. E. Lat. 48. 10. N.

DYEING OF WOOD. The methods by which that process is effected are fully set forth in the "*Annales des Arts et Manufactures*" by Mr. Nils Nyström, of Norköping in Sweden, who also has invented a superior mode of preparing a proper varnish for wood with amber. See AMBER in this SUPPLEMENT.

After describing the process for making the varnish of amber, he proceeds to direct the method of preparing the iron dye for staining wood.

Iron dye.—Take eight parts of iron filings, and thirty-two of aqua fortis. The nitric acid (or aqua fortis) should previously be diluted with sixteen parts of water, in a vessel of stone-ware, before we add the iron filings. We should then stir this mixture with a wooden spatula. This preparation ought to be made under a chimney; on account of the effervescence and disengagement of inflammable air (hydrogene gas) which takes place. The vessel which we use ought to be twice as large, at least, as the quantity of the mixture would fill, in order that it may be prevented from overflowing during the effervescence. When the iron has been dissolved, the mixture has acquired a yellowish-brown colour, and as soon as it has cooled, let it be put into an open bottle, and placed upon a sand-bath; and there let it remain for the space of eight-and-forty hours, taking care frequently to shake the bottle during that time. When the deposition has taken place, the solution should be poured into flasks, which ought to be carefully corked: it will then be fit for use.

If this preparation has been made with the requisite care, we shall obtain a solution of a yellowish colour, which is fit for colouring different kinds of wood. If we have added too much water, or if the aqua fortis has been too weak, a deep brown colour is produced; in which case, we must add a quantity of nitric acid, till the yellow shade appears.

This dye may be applied to every kind of wood, except the oak, which, as soon as it is applied to it, becomes entirely black; it also communicates to other kinds of wood different colours, according as it is applied in a larger or smaller quantity. The most common shades are the yellow-brown, and the deep-brown, with streaks or spots of a brownish red.

The experience of four years has demonstrated the durability of this kind of dye; it resists the action of the air, of the light, and even of the direct rays of the sun, without undergoing any alteration. M. Nyström has exposed specimens of wood, stained in this manner, in the most disadvantageous situations, without their colours having been perceptibly affected.

Dye of Fernambouc wood.—Take eight parts of Fernambouc wood, four of alum, and four of red ochre pulverised. Pour water upon this mixture, and let it infuse for the space of twenty-four hours; then reduce it to a quarter of the quantity, by boiling, after which, strain it through a piece of fine linen, and put the liquid into bottles, to be used as you may have occasion for it.

When we make use of these dyes, we may plunge the pieces of wood into them, so that they may penetrate into them on all sides. If we take one part of the iron dye, and dilute it again with three parts of water; if we then pour it upon several pieces of wood, which are to be kept by force under the fluid; and finally, if we deposit this preparation in a warm chamber, the wood will in a short time be penetrated by the liquor to the depth of a quarter of an inch, and in some parts the liquor will penetrate still deeper.

It is to be observed, that the dyeing liquid should be more or less diluted with water, according as the natural colour of the wood is more or less deep, or charged with gallic acid. The pieces of wood must be frequently turned in order that all their

surfaces may be equally exposed to the action of the dye, and acquire an uniform tinge. The same process may also be used with the Fernambouc dye. This method, however, is only applicable to pieces of wood of certain dimensions; for dyeing large pieces a different one must be adopted.

In order to dye the white woods with the two compositions already described, the piece of wood ought to be rubbed, five different times, with a sponge dipped in the iron dye, till it has acquired a mahogany colour. During this application, the wood must remember frequently to shake the liquor, as the oxyde of iron always falls to the bottom. It is also necessary that we should suffer the wood to dry, after each application, before we proceed to the next. When the wood has properly dried, it must be rubbed once or twice with linseed oil, always letting it dry after each application. The more the wood is imbued with the linseed oil, the more mellow are the colours. Another advantage which results from this process is, that the wood does not absorb so much of the amber-varnish, which is expensive, and which is thus compelled to remain upon the surface, to which it gives a gloss.

The wood being prepared in this manner, it is done over with an uniform coat of amber-varnish, by passing once or twice over it a sponge dipped in this varnish, till the surface has acquired a very bright gloss. If the wood has been well imbued with linseed oil, a single coating of varnish will be sufficient; though some articles of furniture, such as bedsteads, chests of drawers, chairs, &c. which are exposed to constant use, and to considerable friction, require the application of several coatings, between each of which the varnish should be suffered to dry.

When the wood has been varnished, any inequalities or ruggednesses that may remain upon it are removed, after the varnish has completely dried, by polishing it with reeds, after which one more coating of varnish is applied, to cover the parts that have been laid bare. For applying the varnish, a sponge has been found to be by far the best instrument. It covers the wood in a more uniform manner than the painter's brush, which in general forms streaks in the coating, and frequently leaves hairs in it, which afterwards separate themselves from the surface of the wood. The varnishing-sponge ought, as soon as we have done using it, to be put into a bottle, to preserve it from the contact of the air; for, without this precaution, it would grow hard, and crack, so as to become unfit for use.

In applying the Fernambouc dye, we may proceed according to the same method. When this dye is applied to the wood of the birch, or knotty alder, undulated streaks are formed upon the surface, the dye running in the direction of the fibres. The same effect takes place with the wood of the pine and red fir: for the resinous veins do not attract the dye so strongly as the rest of the wood: but this circumstance, instead of being a disadvantage, frequently adds very much to the beauty of the wood.

These varnishes have been employed by M. Nyström, after the manner that we have described, for all kinds of furniture, and with great success. They have been used for the space of nearly three years, and no change has as yet been observed in their appearance. When the varnish has become dry and hard, it resists the effects of friction and of boiling water; neither is it subject to lose its gloss by age, provided it be not scratched by any hard substance. If ink, or any other coloured liquid, should drop upon it, it does not penetrate, but may be removed by washing the surface of the varnish with warm water. This advantage might alone be sufficient to recommend the application of this varnish to mahogany itself. It possesses the property of hardening the surface of soft woods. Its use is not attended with much expense, eight ounces being sufficient

for varnishing a common table—a card-table for instance. If streaks form in it, the spots that have been injured may be repaired with a new coating of varnish; finally, by varnishing furniture in this manner every four or five years, we may make it appear perpetually new.

Tables, and other large pieces of furniture, made of stained wood, which require a high degree of polish, may be finished with pumice-stone: those of the most even grain and the smoothest surface are to be preferred. The white, or soft woods, generally puff up when the varnish is applied, and thus lose their polish; it is therefore very necessary that they should previously be rubbed with pumice-stone.

In treating of amber-varnish, it might perhaps have been observed, that it may be applied to gilding without producing any considerable change in its lustre, particularly if applied in very thin layers, and in an uniform manner. It is easy to

conceive the advantage of an application, which enables us to clean gilt frames, or other furniture, by washing them with spirit of wine, or even with soap and water, without injury to their brilliancy. It cannot, however, be used for covering false gilding, as this is attacked and discoloured by the varnish. We shall still remark, that it may be used for varnishing all sorts of oil colours, except the blue, to which it gives a greenish tinge. This varnish possesses the advantage, that it never cracks, like those which are prepared with gum-lac and spirit of wine. A prodigious quantity of amber grows on the coasts of the Baltic, from whence it might easily be obtained.

DYNAMICS, a name applied to that department of physico-mathematical science which contains the *abstract doctrine of moving forces*; that is, whatever necessarily results from the relations of our idea of motion, and of the immediate causes of its production and variations.

E.

E A R

EAOOWE, one of the Friendly Islands, in the S Pacific Ocean, discovered by Tasman, in 1643, and by him named Middleburg. The land gently rises to a considerable height, presenting a beautiful prospect of extensive meadows, adorned with tufts of trees, and intermixed with plantations. Long. 174. 30. W. Lat. 21. 24. S.

EARLSTON, or EARSILTON, a town in Berwickshire, seated on the river Leader, 35 miles S.E. of Edinburgh. It is the birth-place of the celebrated Thomas the Rhymer, whose real name was Thomas Lermont: the ruins of the little tower he possessed, still remain at the west end of the town. A little below Earlston, on a rocky bank overlooking the Leader, stands Cowdenknows, an old building, now somewhat modernized; and on the adjacent knolls may be seen the remains of its *broom*, so renowned in Scottish ditty.

EARN, a river, which issues from a lake of the same name, in Perthshire. It meanders for above 20 miles, through the valley of Strathearn, and joins the Tay, below Perth.

EARNE, a lake of Ireland, in the county of Fermanagh, 30 miles in length. It is narrow in the middle; and in this part is an island on which stands Inniskilling.

EARTH (*Encycl.*). In that article, from a supposition that our limits would not admit of the detailed opinions of philosophers on so copious a subject, we avoided an account of the different theories of the Earth. In this place, however, we think it necessary to trace those which are allowed to deserve the greatest share of attention.

For a long time, the philosophy of Aristotle prevailed, and the world was thought to be upheld by forms, qualities, and other unintelligible and imaginary beings.—At last the French philosopher, Descartes, superseded the Aristotelian, by introducing the atomic, or Democritic, and Epicurean philosophy. The Cartesian system, however, was quickly superseded by the Newtonian; which still continues, though considerably different from what it was left by that great man.—His opinions, indeed, concerning the cosmogony seem to have been in a fluctuating state; and hence he delivers himself in such a manner, that he hath often incurred the charge of contradicting himself.—He maintained, for instance, that matter was infinitely divisible, and the mathematical demonstrations of this proposition are well known. Notwithstanding this, however, when he comes particularly to speak of the original construction of the world, he seems to retract this opinion, and adopt

E A R

the atomic philosophy. He tells us, that it seems probable, that in the beginning God formed matter in *solid, massy, impenetrable* particles, &c.; and that of these particles, endowed with various powers of attraction and repulsion, the present system of nature is formed. His primary laws of nature are only three in number, and very simple. The first is, that all matter has a tendency to continue in that state in which it is once placed, whether of rest or motion. If it is at rest, for example, it will continue at rest for ever, without beginning motion of itself; but if it is once set in motion, by any cause whatever, it will for ever continue to move in a right line, until something either stops it altogether, or forces it to move in another direction. 2. That the change of motion is always equivalent to the moving force employed to produce it, and in the direction of the right line in which it is impressed; that is, if a certain force produces a certain motion, double that force will produce double that motion, &c. 3. Reaction is always contrary and equal to action; or the actions of two bodies upon one another are always equal and contrary to one another.

From these three laws, together with the two contrary forces of attraction and repulsion, Sir Isaac Newton and his followers have attempted to explain all the phenomena of nature. When they come to explain the nature of the attractive and repulsive forces, however, they are exceedingly embarrassed. Sir Isaac hath expressed himself in two different ways concerning them. In his Principia, he prettily positively determines them to be owing to a cause that is not material; and in his queries, he supposes they may be effects of some subtle matter which he calls *ether*. This disagreement with himself hath produced no small disagreement among his followers. One party, laying hold of his assertions in the Principia, determine the world to be upheld by immaterial powers; while the other, neglecting the Principia, and taking notice only of the queries at the end of the Optics, strenuously maintain, that attraction and repulsion are owing to the action of some exceedingly fine and subtle ether.—The first of these suppositions, it is argued, necessarily involves us in one of the following dilemmas. 1. If the attractive and repulsive forces are not material, they must either be occasioned by spiritual beings, or they must be qualities of matter. If they are occasioned by the action of immaterial beings, these beings must either be created or uncreated. If they are produced by the action of created beings,

we run into the supposition of some of the ancient heathens, that the world is governed by demons or subordinate intelligences; and thus may make an easy transition to polytheism. If attraction and repulsion are the immediate action of the Deity himself, we run into the doctrine of making God the soul of the world.—This last hypothesis hath been most strenuously adopted by Mr. Baxter in his treatise of the Immateriality of the human Soul. Mr. Boscovich, Mr. Mitchell, and Dr. Priestley, have likewise adopted the hypothesis of immaterial powers to such a degree, that, according to them, the whole world consists of nothing else but attractions and repulsions mixed with physical points. 2. If we suppose the attractive and repulsive powers to be only properties, qualities, or laws, impressed on matter by the Deity, we might as well have been contented with the occult qualities of Aristotle.—If attraction and repulsion are occasioned by the action of mere matter, and all the powers in nature are only material, the charge is incurred of making nature direct itself in such a manner, that there is no occasion for the interposition, or even the existence, of a Deity at all.

Thus we see, the Newtonian cosmogony must incline either to the Platonic and Aristotelian, or to the Atomic or Epicurean; according to the hypothesis we lay down concerning the nature of attraction. Des Cartes's system was plainly a revival of that of Democritus and Epicurus, with some corrections and improvements. It was further improved and corrected by Mr. Hutchinsohn, who added to it the authority of revelation. The created agents he chose in his cosmogony were fire, light, and air. These, we see, have indeed a very considerable share in the operations of nature; but unless we explain the manner in which they operate, our knowledge is not at all increased, and we might as well have been contented with the Newtonian attraction and repulsion, or even the occult qualities of Aristotle. Attempts have indeed been made to solve the phenomena of nature, from the action of these three agents, both by Hutchinsohn himself, and many of his followers.—These attempts, however, have always proved unsuccessful. Some phenomena indeed may be explained pretty plausibly from the known action of these three; but when we come to speak of what may be called the *nicer operations* of nature, such as the growth of plants or animals, we are utterly at a loss.

The manifest deficiency of active principles in all the theories of the earth that have yet been invented, hath occasioned a constant search after others which should be able, by their superior activity, to fill up the blank which necessarily remained in the system.—Pythagoras, Plato, and Aristotle, being unable to account for the formation of the earth from their four elements, called in the assistance of a *fifth*, which was never yet discovered. Epicurus, finding the motions attributed to his atoms by Democritus to be insufficient, had recourse to an imaginary, and on his own principles impossible, declination of the atoms. Descartes finding the atoms themselves insufficient, asserted that they were not atoms, but might be broken into smaller parts, and thus constitute matter of various degrees of subtilty. The Newtonian philosophers have found Des Cartes's system insufficient; but being greatly distressed in their attempts to solve all the phenomena of nature by mere attraction and repulsion, have been obliged to call in the action of *mind* to their assistance. The Hutchinsohnians were hardly put to it in accounting for every thing by the action of fire, light, and air, when luckily the discoveries in electricity came to their assistance. It must be owned, that this fluid does indeed come in like a kind of fifth element, which in many cases appears to be the animating principle of nature. For some time past, almost all the remarkable phenomena in na-

ture have been explained by electricity, or the action of the electric fluid. But unless this action is explained, we are got no further than we were before. To say any thing is done by electricity, is not more intelligible than to say it was done by attraction. If we explain an effect by a material cause, it ought to be done upon mechanical principles. We ought to be sensible how one part of matter acts upon another part in such a manner as to produce the effect we desire to explain. The electrical philosophers, however, have not yet been able to investigate the manner in which this subtle fluid operates; and hence the many discoveries in electricity have not contributed to throw that light on the theory of the earth, which perhaps they may do hereafter. With some philosophers, however, the electric fluid itself, and indeed all the powers of nature, seem in danger of being superseded by a principle, at present very little known, called the *phlogiston*.—Thus, Mr. Henly tells us (*Phil. Trans.* vol. 67), that Mr. Clarke, an ingenious gentleman in Ireland, hath discovered all the different kinds of air produced from metals, &c. by Dr. Priestley, to be only *phlogistic vapours* arising from these substances. Dr. Priestley himself supposes, that the electric light is a modification of *phlogiston*; and consequently thinks it probable, that all light is a modification of the same. Fire or flame is thought to be a chemical combination of air with the phlogiston; and phlogiston is thought to give the elasticity to air, and every other elastic fluid, &c.—Be this as it will, however, the late discoveries in electricity have tended very much to change the form of the Newtonian philosophy, and to introduce that *materialism* into our theories of the natural phenomena which is by some people so much complained of.

From this general history of the different agents which philosophers have chosen to account for the original formation of the earth, and for its preservation in the present form, it appears, that scarce any advance in true knowledge hath yet been made. All the agents have been prodigiously defective; electricity itself, as far as yet known, not excepted. But, before entering into a particular consideration of those theories which seem most worthy of notice, it will be necessary to point out the principal difficulties which stand in the way of one who attempts to give a complete theory of the earth.

1. The earth, although pretty much of a spherical figure, is not completely so; but protuberates considerably about the equatorial parts, and is proportionally flattened at the poles, as is undeniably proved by the observations of modern mathematicians. The question here is, Why the natural cause which gave the earth so much of a spherical figure, did not make it a complete and exact sphere?

2. The terraqueous globe consists of a vast quantity of water as well as dry land. In many places, such as the isthmus of Darien, a narrow neck of land is interposed betwixt two vast oceans. These beat upon it on either side with vast force; yet the isthmus is never broke down nor diminished. The case is the same with the isthmus of Suez which joins Asia and Africa, and with that which joins the Morea or ancient Peloponnesus to the continent. The difficulty is, By what natural power or law are these narrow necks of land preserved amidst the waters which threaten them on both sides with destruction?

3. The surface of the earth is by no means smooth and equal; but in some places raised into enormous ridges of mountains, and in others sunk down in such a manner as to form deep valleys. These mountains, though they have been exposed to all the injuries of the weather for many thousand years, exhibit no signs of decay. They still continue of the same size as before, though vast quantities of earth are frequently washed down from them by the rains, which, together with the force of gravity, tending to level and bring them on

an equality with the plains on which they stand, we might reasonably think, ought by this time to have rendered them smaller than before. It must therefore be enquired into, By what natural cause the mountains were originally formed, and how they come to preserve their size without any remarkable diminution?

4. The internal parts of the earth are still more wonderful than the external. The utmost industry of man, indeed, can penetrate but a little way into it. As far as we can reach, however, it is found to be composed of dissimilar strata lying one upon another, not commonly in a horizontal direction, but inclined to the horizon at different angles. These strata seem not to be disposed either according to the laws of gravity or according to their density, but as it were by chance. Besides, in the internal parts of the earth are vast chasms and vacuities. By what means were these strata originally deposited, the fissures and chasms made, &c.?

5. In many places of the earth, both on the surface, and at great depths under it, vast quantities of marine productions, such as shells, &c. are to be met with. Sometimes these shells are found in the midst of solid rocks of marble and lime-stone. In the very heart of the hardest stones also, small vegetable substances, as leaves, &c. are sometimes to be found. The question is, By what means were they brought thither?

These are some of the most striking difficulties which present themselves to one who undertakes to write a natural history or theory of the earth. The most remarkable attempts to produce a theory of this kind are those of Burnet, Woodward, Whiston, and Buffon.

According to Dr. Burnet, the earth was originally a fluid mass, or chaos, composed of various substances differing both in density and figure. Those which were most heavy sunk to the centre, and formed there a hard solid body: those which were specifically lighter remained next above; and the waters, which were lightest of all, covered the earth all round. The air, and other ethereal fluids, which are still lighter than water, floated above it, and surrounded the globe also. Between the waters, however, and the circumambient air, was formed a coat of oily and unctuous matters lighter than water. The air at first was very impure, and must necessarily have carried up with it many of those earthy particles with which it was once blended; however, it soon began to purify itself, and deposit those particles upon the oily crust above mentioned; which, soon uniting together, the earth and oil became the crust of vegetable earth, with which the whole globe is now covered. His account of the destruction of the primeval world by the flood, by the falling down of the shell of earth into the waters of the abyss, is given under the article *DELUGE*. It only remains then to give his account of the manner in which he relieves the earth from this universal destruction; and this he does as follows. These great masses of earth, says he, falling into the abyss, drew down with them vast quantities also of air; and by dashing against each other, and breaking into small parts by the repeated violence of the shock, they at length left between them large cavities filled with nothing but air. These cavities naturally offered a bed to receive the influent waters; and in proportion as they filled, the face of the earth became once more visible. The higher parts of its broken surface, now become the tops of mountains, were the first that appeared; the plains soon after came forward; and at length the whole globe was delivered from the waters, except the places in the lowest situations; so that the ocean and seas are still a part of the ancient abyss, that have had no place to which they might return. Islands and rocks are fragments of the earth's former crust; continents are larger masses of its broken substance; and all the inequalities that are to be found

on the surface of the present earth are effects of the confusion into which both earth and water were at that time thrown.

Dr. Woodward begins with asserting, that all terrene substances are disposed in beds of various natures, lying horizontally one over the other, somewhat like the coats of an onion: that they are replete with shells, and other productions of the sea; these shells being found in the deepest cavities, and on the tops of the highest mountains. From these observations, which are warranted by experience, he proceeds to observe, that these shells, and extraneous fossils, are not productions of the earth, but are all actual remains of those animals which they are known to resemble; that all the strata or beds of the earth lie under each other in the order of their specific gravity, and that they are disposed as if they had been left there by subsiding waters. All this he very confidently affirms, though daily experience contradicts him in some of them; particularly, we often find layers of stone over the lightest soils, and the softest earth under the hardest bodies. However, having taken it for granted, that all the layers of the earth are found in the order of their specific gravity, the lightest at top, and the heaviest next the centre, he consequently asserts, that all the substances of which the earth is composed, were originally in a state of dissolution. This dissolution he supposes to have taken place at the flood: but being aware of an objection, that the shells, &c. supposed to have been deposited at the flood are not dissolved, he exempts them from the solvent power of the waters, and endeavours to shew that they have a stronger cohesion than minerals; and that, while even the hardest rocks are dissolved, bones and shells may remain entire.

Mr. Whiston supposes the earth to have been originally a comet; and considers the Mosaic account of the creation as commencing at the time when the Creator placed this comet in a more regular manner, and made it a planet in the solar system. Before that time, he supposes it to have been a globe without beauty or proportion; a world in disorder, subject to all the vicissitudes which comets endure; which, according to the present system of philosophy, must be alternately exposed to the extremes of heat and cold. These alternations of heat and cold, continually melting and freezing the surface of the earth, he supposes to have produced, to a certain depth, a chaos resembling that described by the poets, surrounding the solid contents of the earth, which still continued unchanged in the midst; making a great burning globe of more than 2000 leagues in diameter. This surrounding chaos, however, was far from being solid: he resembles it to a dense, though fluid atmosphere, composed of substances mingled, agitated, and shocked against each other; and in this disorder he supposes the earth to have been just at the eve of the Mosaic creation. But upon its orbit being then changed, when it was more regularly wheeled round the sun, every thing took its proper place, every part of the surrounding fluid then fell into a certain situation according as it was light or heavy. The middle, or central part, which always remained unchanged, still continued so; retaining a part of that heat which it received in its primeval approaches towards the sun; which heat he calculates may continue about 6000 years. Next to this fell the heavier parts of the chaotic atmosphere, which serve to sustain the lighter; but as in descending they could not entirely be separated from many watery parts, with which they were intimately mixed, they drew down these also along with them; and these could not mount again after the surface of the earth was consolidated: they therefore surrounded the heavy first-descending parts in the same manner as these surrounded the central globe. Thus the entire body of the earth is composed next the centre of a great burning globe: next this is placed an heavy terrene substance that encompasses it; round which is

circumsufed a body of water. Upon this body of waters is placed the crust of earth on which we inhabit : so that, according to Mr. Whiston, the globe is composed of a number of coats, or shells, one within the other, all of different densities. The body of the earth being thus formed, the air, which is the lightest substance of all, surrounded its surface, and the beams of the sun darting through, produced the light, which, we are told by Moses, first obeyed the Divine command.

The whole economy of the creation being thus adjusted, it only remained to account for the risings and depressions on the surface of the earth, with the other seeming irregularities of its present appearance. The hills and valleys are by him considered as formed by their pressing upon the internal fluid which sustains the external shell of the earth, with greater or less weight ; those parts of the earth which are heaviest sink the lowest into the subjacent fluid, and thus become valleys : those that are lightest rise higher upon the earth's surface, and are called *mountains*.

Such was the face of nature before the deluge : the earth was then more fertile and populous than it is at present ; the life of men and animals was extended to ten times its present duration ; and all these advantages arose from the superior heat of the central globe, which has ever since been cooling. As its heat was then in its full power, the genial principle was also much greater than at present ; vegetation and animal increase were carried on with more vigour ; and all nature seemed teeming with the seeds of life. But as these advantages were productive only of moral evil, it was found necessary to destroy all living creatures by a flood ; and in what manner this punishment was accomplished, according to Mr. Whiston, is taken notice of under the article *DELUGE*.

Mr. Buffon's theory differs very widely from all the rest. He begins with attempting to prove, that this world which we inhabit is no more than the ruins of a world. " The surface of this immense globe (says he), exhibits to our observation, heights, depths, plains, seas, marshes, rivers, caverns, gulfs, volcanoes ; and, on a cursory view, we can discover in the disposition of these objects neither order nor regularity. If we penetrate into the bowels of the earth, we find metals, minerals, stones, bitumens, sands, earths, waters, and matter of every kind, placed as it were by mere accident, and without any apparent design. Upon a nearer and more attentive inspection, we discover sunk mountains, caverns filled up, shattered rocks, whole countries swallowed up, new islands emerged from the ocean, heavy substances placed above light ones, hard bodies inclosed within soft bodies ; in a word, we find matter in every form, dry and humid, warm and cold, solid and brittle, blended in a chaos of confusion, which can be compared to nothing but a heap of rubbish, or the ruins of a world."

When taking a particular survey of the external surface of the globe, he begins with the ocean, and the motion communicated to it by the influence of the sun and moon which produces the tides.—" In examining the bottom of the sea (says he), we perceive it to be equally irregular as the surface of the dry land. We discover hills and valleys, plains and hollows, rocks and earths of every kind ; we discover likewise, that islands are nothing but the summits of vast mountains, whose foundations are buried in the ocean. We find other mountains whose tops are nearly on a level with the surface of the water ; and rapid currents which run contrary to the general movement. These currents sometimes run in the same direction ; at other times their motion is retrograde ; and they never exceed their natural limits, which seem to be as immutable as those which bound the efforts of land-rivers. On one hand we meet with tempestuous regions, where the winds blow with irresistible fury ; where the heavens and the ocean, equally con-

vulsed, are mixed and confounded in the general shock ; violent intestine motions, tumultuous swellings, water-spouts, and strange agitations, produced by volcanoes, whose mouths, though many fathoms below the surface, vomit forth torrents of fire ; and puff, even to the clouds, a thick vapour, composed of water, sulphur, and bitumen ; and dreadful gulfs or whirlpools, which seem to attract vessels for no other purpose than to swallow them up. On the other hand we discover vast regions of an opposite nature, always smooth and calm, but equally dangerous to the mariner. To conclude, directing our eyes toward the southern or northern extremities of the globe, we discover huge masses of ice, which, detaching themselves from the polar regions, advance, like floating mountains, to the temperate climates, where they dissolve and vanish from our view. The bottom of the ocean and the shelving sides of rocks produce plentiful crops of plants of many different species : its soil is composed of sand, gravel, rocks, and shells ; in some places it is a fine clay, in others a compact earth : and in general, the bottom of the sea has an exact resemblance to the dry land which we inhabit.

" Let us next take a view of the dry land. Upon an attentive observation of this, we shall find, that the great chains of mountains lie nearer the equator than the poles ; that in the old continent their direction is more from east to west than from south to north ; and that, on the contrary, in the new continent they extend more from north to south than from east to west. But what is still more remarkable, the figure and direction of these mountains, which have a most irregular appearance, correspond so wonderfully, that the prominent angles of one mountain are constantly opposite to the concave angles of the neighbouring mountain, and of equal dimensions, whether they be separated by an extensive plain or a small valley. I have further remarked, that opposite hills are always nearly of the same height ; and that mountains generally occupy the middle of continents, islands, and promontories, dividing them by their greatest lengths. I have likewise traced the courses of the principal rivers, and find that their direction is nearly perpendicular to the sea-coasts into which they empty themselves ; and that, during the greatest part of their courses, they follow the direction of the mountains from which they derive their origin. The sea-coasts are generally bordered with rocks of marble, and other hard stones ; or rather with earth and sand accumulated by the waters of the sea, or brought down and deposited by rivers. In opposite coasts, separated only by small arms of the sea, the different strata or beds of earth are of the same materials. I find that volcanoes never exist but in very high mountains ; that a great number of them are entirely extinguished ; that some are connected to others by subterranean passages, and their eruptions not unfrequently happen at the same time. There are similar communications between certain lakes and seas. Some rivers suddenly disappear, and seem to precipitate themselves into the bowels of the earth. We likewise find certain mediterranean or inland seas, that constantly receive from many and great rivers prodigious quantities of water, without any augmentation of their bounds ; probably discharging by subterraneous passages all those extraneous supplies. It is likewise easy to distinguish lands which have been long inhabited, from those new countries where the earth appears in a rude state, where the rivers are full of cataracts, where the land is nearly overflowed with water or burnt up with drought, and where every place capable of producing trees is totally covered with wood.

" Proceeding in our examination, we discover that the upper stratum of the earth is universally the same substance : that this substance, from which all animals and vegetables derive their growth and nourishment, is nothing but a composition of the decayed parts of animal and vegetable bodies,

reduced into such small particles that their former organic state is not distinguishable. Penetrating a little deeper, we find the real earth, beds of sand, limestone, clay, shells, marble, gravel, chalk, &c. These beds are always parallel to each other, and of the same thickness throughout their whole extent. In neighbouring hills, beds or strata of the same materials are uniformly found at the same levels, though the hills be separated by large and deep valleys. Strata of every kind, even of the most solid rocks, are uniformly divided by perpendicular fissures. Shells, skeletons of fishes, marine plants, &c. are often found in the bowels of the earth, and on the tops of mountains, even at the greatest distances from the sea. These shells, fishes, and plants, are exactly similar to those which exist in the ocean. Petrified shells are to be met with almost every-where in prodigious quantities; they are not only enclosed in rocks of marble and lime-stone, as well as in earths and clays, but are actually incorporated and filled with the very substances in which they are enclosed. In fine, I am convinced, from repeated observation, that marbles, lime-stones, chalks, marbles, clays, sand, and almost all terrestrial substances, wherever situated, are full of shells and other spoils of the ocean."

From these positions, which he lays down as facts, Mr. Buffon draws the following conclusions:

1. The changes which the earth has undergone within these last 2000 or 3000 years must be inconsiderable, when compared with the great revolutions that took place in those ages immediately succeeding the creation. The reason he gives for this assertion is, that terrestrial substances could not acquire solidity but by the continued action of gravity: hence, the earth must have been originally much softer than it is now, and therefore more apt to be changed by causes which cannot now affect it.

2. It seems an uncontrovertible fact, that the dry land which we now inhabit, and even the summits of the highest mountains, were formerly covered with the waters of the sea; for shells and other marine bodies are still found upon the very tops of mountains.

3. The waters of the sea have remained for a long track of time upon the surface; because in many places, such immense banks of shells have been discovered, that it is impossible to great a multitude of animals could exist at the same time.

4. From this circumstance it likewise appears, that although the materials on the surface of the earth were then soft, easily disunited, moved, and transported by the waters, yet these transportations could not be suddenly effected: they must have been gradual and successive, as sea-bodies are sometimes found more than 1000 feet below the surface: and such a thickness of earth, or stone, could not be accumulated in a short time.

5. It is impossible these effects could be owing to the universal deluge. For, though we should suppose that all the shells in the bottom of the ocean should be deposited upon the dry land; yet, besides the difficulty of establishing this supposition, it is plain, that as shells are found incorporated in marble, and in the rocks of the highest mountains, we must suppose these rocks and marbles to have been formed all at the very instant when the deluge took place; and that before this grand revolution, there were neither mountains, nor marbles, nor rocks, nor clays, nor matter of any kind similar to what we are now acquainted with; as they all, with few exceptions, contain shells, and other productions of the ocean. Besides, at the time of the universal deluge, the earth must have acquired a considerable degree of solidity, by the action of gravity for more than 16 centuries. During the short time the deluge lasted, therefore, it is impossible that the waters

should have overturned and dissolved the whole surface of the earth to the greatest depths.

6. It is certain (for what reason he does not mention), that the waters of the sea have, at some period or other, remained for a succession of ages upon what we now know to be dry land; and consequently that the vast continents of Asia, Europe, Africa, and America, were then the bottom of an immense ocean, replete with every thing which the present ocean produces.

7. It is likewise certain, that the different strata of the earth are horizontal and parallel to each other. This parallel situation must therefore be owing to the operation of the waters, which have gradually accumulated the different materials, and given them the same position which the water itself invariably assumes.

8. It is certain that these strata must have been gradually formed, and are not the effect of any sudden revolution; because nothing is more frequent than strata composed of heavy materials placed above light ones; which never could have happened, if, according to some authors, the whole had been blended and dissolved by the deluge, and afterwards precipitated.

9. No other cause than the motion and sediments of water could possibly produce the regular position of the various strata of which the superficial part of this earth consists. The highest mountains are composed of parallel strata, as well as the lowest valleys. Of course, the formation of mountains cannot be attributed to the shocks of earthquakes, or to the eruptions of volcanoes. Such small eminences as have been raised by volcanoes or convulsions of the earth, instead of becoming composed of parallel strata, are mere masses of weighty materials, blended together in the utmost confusion.

Having now, as he thinks, *proved*, that the dry and habitable part of the earth has remained for a long time under the waters of the sea, and consequently must have undergone the same changes that now take place at the bottom of the sea, he proceeds to enquire what these changes are.

10. The ocean, since the creation of the world, has been constantly agitated by the tides, occasioned by the action of the sun and moon; and this agitation is greater in the equatorial than in the other parts of the globe, because the action of the sun and moon is there strongest.

11. The earth performs a rapid motion on its axis; and consequently its parts have a centrifugal force, which is also greatest at the equator.

12. From the combined action of the two last-mentioned causes, the tides, and the motion of the earth, it may be fairly concluded, that although this globe had been originally a perfect sphere, its diurnal motion, and the ebbing and flowing of the tides, must necessarily, in a succession of time, have elevated the equatorial parts, by gradually carrying mud, earth, sand, shells, &c. from other climates, and depositing them at the equator.

13. On this supposition, the greatest inequalities on the surface of the earth ought to be found, and in fact are found, in the neighbourhood of the equator.

14. As the alternate motion of the tides has been constant and regular since the existence of the world, it is natural to think, that at each tide, the water carries from one place to another a small quantity of matter, which falls to the bottom as a sediment, and forms those horizontal and parallel strata that every-where appear. Here it may indeed be objected, that as the flux is equal to, and regularly succeeded by, the reflux, the two contrary motions will balance each other; and whatever is brought in by the flux will be carried back by the reflux. The motion of the ocean, therefore, could

never be the cause of the formation even of parallel strata; much less of mountains, and all the inequalities to be observed in this globe. To this Mr. Buffon replies, that the alternate motion of the waters is by no means equal; for the sea has a continual motion from east to west: the agitations occasioned by the winds likewise produce great inequalities in the tides. It must also be acknowledged, that, by every motion of the sea, particles of earth and other matter must be carried from one place and deposited in another; and that these collections of matter must assume the form of parallel and horizontal strata. Lastly, this objection is obviated by a well-known fact. On all coasts where the ebbing and flowing of the sea is discernible, numberless materials are brought in by the flux, which are not carried back by the reflux. The sea gradually increases on some places and recedes from others; narrowing its limits by depositing earth, sand, shells, &c. which naturally take a horizontal position. These materials when accumulated, and elevated to a certain degree, gradually shut out the water, and remain for ever in the form of dry land.

15. The possibility of a mountain's being formed at the sea by the motion and sediments of the water, will appear from the following considerations. On a coast which the sea washes with violence during the flow of tide, some part of the earth must be carried off at every stroke of the waves. Even where the sea is bounded by rock, it is a known fact, that the rock itself is greatly wasted by the water; and consequently that small particles are carried off by the retreat of every wave. Those particles of earth or stone are necessarily transported to some distance. Whenever the agitation of the water ceases, the particles are precipitated in the form of a sediment, and lay the foundation of a first stratum, which is either horizontal or inclined, according to the situation of the surface on which they fall. This stratum is soon succeeded by another, produced by the same cause; and thus a considerable quantity of matter will be amassed, and deposited in parallel beds. In process of time this gradually accumulating mass will become a mountain in the bottom of the sea, exactly resembling both in external and internal structure, those mountains which we see on the dry land. If there happened to be shells in that part of the bottom of the sea where we have supposed the sediments to be deposited, they will be covered, filled, and incorporated with the deposited matter, and form a part of the general mass. These shells will be lodged in different parts of the mountain, corresponding to the times in which they were deposited: those which lay at the bottom before the first stratum was formed, will occupy the lowest situation; the others will be found in places more elevated.

16. It has been imagined that the agitation of the sea produced by the winds and tides is only superficial, and does not affect the bottom, especially where it lies very deep. But it ought to be remembered, that whatever be the depth, the whole mass is put in motion by the tides at the same time; and that, in a fluid globe, this motion would be communicated even to the centre. The attractive power, which occasions the flux and reflux, is penetrating. It acts equally upon every particle of the mass; so that the quantity of its force at different depths may be determined by calculation. We cannot therefore hesitate in pronouncing, that the tides, the winds, and all other causes of motion in the sea, must produce heights and inequalities in its bottom; and that these heights must uniformly be composed of regular strata either horizontal or inclined. The heights thus produced will gradually augment; like the waves which formed them, they will mutually respect each other; and if the extent of the base be great, in a course of years they will form a vast chain of mountains.

Whenever eminences are formed, they interrupt the uniform motion of the waters, and produce currents. Between two neighbouring heights in the bottom of the ocean there must be a current which will follow their common direction, and, like a river, cut a channel, the angles of which will be alternately opposite through the whole extent of its course. These heights must continually increase: for, during the flow, the water will deposit its ordinary sediment upon their ridges; and the waters which are impelled by the current will force along, from great distances, quantities of matter, which will subside between the hills, and, at the same time, scoop out a valley with corresponding angles at their foundation. Now, by means of these different motions and sediments, the bottom of the ocean, though formerly smooth, must soon be furrowed and interspersed with hills and chains of mountains, as we actually find it at present. The soft materials of which the eminences were originally composed, would gradually harden by their own gravity. Such of them as consisted of sandy and crystalline particles, would produce those enormous masses of rock and flint, in which we find crystals and other precious stones. Others, composed of stony particles mixed with shells, give rise to those beds of lime-stone and marble in which vast quantities of sea-shells are still found incorporated.

18. These causes, as before observed, act with greater force under the equator than in other climates; for there the tides are higher, and the winds more uniform. The mountains of Africa and Peru are the highest in the world; often extending through whole continents, and stretching to great distances under the waters of the ocean. The mountains of Europe and Asia, which extend from Spain to China, are not so high as those of Africa and South America. According to the relations of voyagers, the mountains of the north are but small hills, when compared with the mountains of the equatorial regions. Those prodigious chains of mountains which run from east to west in the old continent, and from north to south in the new, must have been formed by the general motion of the tides. But the origin of the less considerable hills must be ascribed to particular motions occasioned by the winds, currents, and other irregular agitations of the sea.

Having thus discussed some very important points respecting the theory of the earth, our author now proceeds to answer other questions which seem still more difficult of solution.

19. But how has it happened that this earth, which we and our ancestors have inhabited for ages, which, from time immemorial, has been an immense continent, dry, compact, and removed from the reach of water, should, if formerly the bottom of an ocean, be now exalted to such a height above the waters, and so completely separated from them? Since the waters remained so long upon the earth, why have they now deserted it? What accident, what cause, could introduce a change so great? A little reflection, says he, will furnish us with at least plausible solutions to these seemingly so difficult questions. We daily observe the sea gaining ground on certain coasts, and losing it on others. We know that the ocean has a general and uniform motion from east to west; that it makes violent efforts against the rocks and low grounds which encircle it; that there are whole provinces which human industry can hardly defend against the fury of the waves; and that there are instances of islands which have but lately emerged from the waters, and of regular inundations. History informs us of inundations and deluges of a more extensive nature. Ought not all this to convince us, that the surface of the earth has experienced very great revolutions, and that the sea may have actually given up possession of the greatest part of the ground which it formerly occupied? For example, let us suppose,

that the old and new worlds were formerly but one continent ; and that, by a violent earthquake, the ancient Atlantis of Plato was sunk. The consequence of this mighty revolution must necessarily be, that the sea would rush in from all quarters, and form what is now called the *Atlantic ocean*; and vast continents, perhaps those we now inhabit, would of course be left dry. This great revolution might be effected by the sudden failure of some immense cavern in the interior parts of the globe, and an universal deluge would infallibly succeed.

20. But, however conjectures of this kind may stand, it is certain that such a revolution hath happened ; and we may even believe that it hath happened naturally ; for if a judgment of the future is to be formed from the past, we have only to attend carefully to what passes before our eyes. It is a fact established by the repeated observation of voyagers, that the ocean has a constant motion from east to west. This motion, like the trade-winds, is not only perceived between the tropics, but through the whole temperate climates, and as near the poles as navigators have approached. As a necessary consequence of this motion, the Pacific ocean must make continual efforts against the coasts of Tartary, China, and India ; the Indian ocean must act against the east coast of Africa ; and the Atlantic must in a similar manner act against all the eastern coasts of America. Hence the sea must have gained, and will always continue to gain, on the east, and to lose on the west. This of itself would be sufficient to prove the possibility of the change of the sea into land, and land into sea. If such is the natural effect of the sea's motion from east to west, may it not reasonably be supposed, that Asia, and all the eastern continent, is the most ancient country in the world ; and that Europe, and part of Africa, especially the west parts of these continents, as Britain, France, Spain, &c. are countries of a more recent date ?

21. The cause of the perpendicular fissures with which the earth abounds, is easily investigated. As various materials constituting the different strata were transported by the waters, and deposited in the form of sediments, they would at first be in a very dilated state, and would gradually harden and part with the superfluous quantity of moisture they contained. In process of time, drying, they would naturally contract and split at irregular distances. These fissures necessarily assumed a perpendicular direction ; because in this direction the action of gravity of one particle upon another is equal to nothing : but it acts directly opposite to this description, in a horizontal situation : the diminution in bulk could have no sensible effect but in a vertical line. The contraction of the parts in drying, therefore, and not the contained water forcing an issue, as has been alleged by some, is the cause of perpendicular fissures ; for it may be often remarked, that the sides of those fissures, through their whole extent, correspond as exactly as the two sides of a split piece of wood.

22. Perpendicular fissures vary greatly as to the extent of their openings. Some are about half an inch or an inch ; others a foot or two feet ; some extend several fathoms, and give rise to those vast precipices which so frequently occur between opposite parts of the same rocks, in the Alps and other high mountains. It is plain, that the fissures, the openings of which are small, have been occasioned solely by drying. But those which extend several feet are partly owing to another cause ; namely, the sinking of the foundation upon one side, while that of the other remains firm. If the base sinks but a line or two, when the height is considerable, an opening of several feet, or even fathoms, will be the consequence. When rocks are founded on clay or sand, they sometimes slip a little to one side ; and the fissures are of course augmented by this motion.

23. The large openings, however, and prodigious cuts,

which are to be met with in rocks and mountains, are to be ascribed to another cause. They could be produced no other way than by the sinking of immense subterraneous caverns, that were unable any longer to sustain their incumbent load. But these cuts or intervals in mountains are not of the same nature with the perpendicular fissures : they appear to have been ports opened by the hand of nature for the communication of nations. This seems to be the intention of all large openings in chains of mountains, and of those straits by which different parts of the ocean are connected ; as the straits of Thermopylæ, of Gibraltar, &c. the gaps or ports in mount Caucasus, the Cordilleras, &c.

24. But the greatest changes upon the surface of the earth are occasioned by rains, rivers, and torrents from the mountains. These derive their origin from vapours raised by the sun from the surface of the ocean, and which are transported by the winds through every climate. The progress of these vapours, which are supported by the air, and transported at the pleasure of the winds, is interrupted by the tops of the mountains, where they accumulate into clouds, and fall down in the form of rain, dew, or snow. At first, these waters descended into the plains without any fixed course ; but they gradually hollowed out proper channels for themselves. By the power of gravity they ran to the bottom of the mountains ; and penetrating or dissolving the lower grounds, they carried along with them sand and gravel, cut deep furrows in the plains, and thus opened passages to the sea, which always receives as much water by rivers as it loses by evaporation. The windings in the channels of rivers have uniformly corresponding angles on their opposite banks ; and as mountains and hills, which may be regarded as the banks of the valleys by which they are separated, have likewise sinuosities with corresponding angles, this circumstance seems to demonstrate, that the valleys have been gradually formed by currents of the ocean, in the same manner as the channels of rivers have been produced. Rivers produce considerable changes on the surface of the earth ; they carry off the soil, wear away the most solid rocks, and remove every thing that opposes their passage. The waters of the clouds also, which descend upon the mountains, by continually washing away some part of the earth, tend to level them with the plains ; and would undoubtedly do so, if time enough were allowed for that purpose.

25. From what has been advanced, we may conclude, that the flux and reflux of the ocean have produced all the mountains, valleys, and other inequalities on the surface of the earth : that currents of the sea have scooped out the valleys, elevated the hills, and bestowed on them the corresponding directions : that the same waters of the ocean, by transporting and depositing earth, &c. have given rise to the parallel strata : that the waters from the heavens gradually destroy the effects of the sea, by continually diminishing the heights of the mountains, filling up the valleys, and choking up the mouths of rivers ; and by reducing every thing to its proper level, they will in time restore the earth to the sea, which by its natural operations will again create new continents interspersed with mountains and valleys, and every way similar to those which we now inhabit.

Thus far our author preserves some degree of plausibility in his reasoning ; but in his account of the original formation of the earth, he certainly goes to the utmost verge of *probability*, or perhaps of *possibility*, in his suppositions. According to him, all the planets in our system were originally parts of the sun himself. They were detached from his body all at once by a mighty stroke of a comet. The possibility of driving off such a quantity of matter from the sun by a single stroke, he labours hard to prove ; but this is far from being the greatest difficulty in his system.—“ To this theory,” says he, “ it may

be objected, that if the planets had been driven off from the sun by a comet, in place of describing circles round him, they must, according to the law of projectiles, have returned to the same place from whence they had been forced; and therefore, that the projectile force of the planets cannot be attributed to the impulse of a comet.

"I reply, that the planets issued not from the sun in the form of globes, but in the form of torrents; the motion of whose anterior particles behaved to be accelerated by those behind, and the attraction of the anterior particles would also accelerate the motion of the posterior; and that this acceleration, produced by one or both of these causes, might be such as would necessarily change the original motion arising from the impulse of the comet; and that, from this cause, might result a motion similar to what takes place in the planets; especially when it is considered, that the shock of the comets removes the sun out of its former station. This reasoning may be illustrated by an example. Suppose a musket-ball discharged from the top of a mountain, and that the force of the powder was sufficient to send it beyond a semidiameter of the earth: it is certain that this ball would revolve round the earth, and return at every revolution to the place from whence it had been discharged. But, instead of a musket-ball, if a rocket were employed, the continued action of the fire would greatly accelerate the original impulsive motion. This rocket would by no means return to the same point like the ball; but, *ceteris paribus*, would describe an orbit, the perigee of which would be more or less distant from the earth in proportion to the greatness of the change produced in its direction by the accelerating force of the fire. In the same manner, if the original projectile force impressed by the comet on the torrent of solar matter was accelerated, it is probable, that the planets formed by this torrent acquired their circular or elliptical movements around the sun."

In like manner, he accounts for the formation and circulation of the secondary planets. The revolutions of the primaries on their axes, he accounts for from the obliquity of the original stroke impressed by the comet. The oblate spheroidal figure of the earth is easily deduced from its diurnal motion, and the fluidity of the whole at its first formation. The flattening at the poles he estimates at about one 230th part of the whole. As this computation differs considerably from the account given by the mathematicians who were sent to different parts of the world on purpose to determine the figure of the earth, and who made the flatness at the poles equal to one 175th part of the whole, he supposes this difference to have arisen from changes that have since taken place on the surface of the earth, occasioned by the causes already mentioned. He then proceeds to account for the formation of all things, in the following manner.—"It is therefore evident, that the earth assumed its figure when in a melted state: and, to pursue our theory, it is natural to think, that the earth, when it issued from the sun, had no other form but that of a torrent of melted and inflamed matter: that this torrent, by the mutual attraction of its parts, took on a globular figure, which its diurnal motion changed into a spheroid: that when the earth cooled, the vapours, which are expanded like the tail of a comet, gradually condensed, fell down in the form of water upon the surface, depositing at the same time a slimy substance mixed with sulphur and salts; part of which was carried by the motion of the waters into the perpendicular fissures of the strata, and produced metals; and the rest remained on the surface, and gave rise to the vegetable mold, which abounds in different places, with more or less of animal or vegetable particles, the organization of which is not obvious to the senses.

"Thus the interior parts of the globe were originally composed of vitrified matter; and, I believe, they are so at present. Above this vitrified matter were placed those bodies which the fire had reduced to the smallest particles, as sands, which are only portions of glass; and above these, pumice-stones, and the scoriae of melted matter, which produced the different clays. The whole was covered with water to the depth of 300 or 600 feet, which originated from the condensation of the vapours when the earth began to cool. This water deposited a stratum of mud, mixed with all those matters which are capable of being sublimed or exhaled by fire: and the air was formed of the most subtle vapours, which, from their levity, rose above the water.

"Such was the condition of the earth when the tides, the winds, and the heat of the sun, began to introduce changes on its surface. The diurnal motion of the earth, and that of the tides, elevated the waters in the equatorial regions, and necessarily transported thither great quantities of slime, clay, and sand; and by thus elevating those parts of the earth, they perhaps sunk those under the poles about two leagues, or a 230th part of the whole, as was formerly remarked: for the waters would easily reduce into powder, pumice-stones, and other spongy parts of the vitrified matter upon the surface; and by this means excavate some places and elevate others, which, in time, would produce islands and continents, and all those inequalities on the surface, which are more considerable towards the equator than towards the poles. The highest mountains lie between the tropics and the middle of the temperate zones, and the lowest from the polar circles towards the poles. Indeed, both the land and sea have most inequalities between the tropics, as is evident from the incredible number of islands peculiar to those regions."

From the preceding extracts, the theories of Drs. Burnet and Woodward, as well as Meir's, Whiston and Buffon, will be easily understood; but the deficiency of all of them must be exceedingly obvious even to the most superficial reader. They all assume only the powers of attraction and repulsion as agents; without considering, that these two powers, or indeed any other two with which mankind are acquainted, could only have composed matters nearly similar to each other. If the original particles of matter are homogeneous, and endowed with similar powers, all the matters we see ought to be homogeneous also. But this is far from being the case. Some parts of it we see are exceedingly hard, others proportionably soft. The parts of some bodies attract each other violently; those of others have hardly any attraction for each other, but are separable by the smallest force. And though it should be granted, that the powers of attraction and repulsion were originally different in different parts of matter, we have still to explain by what means the similar parts of matter found out each other in such a chaos as the earth originally was. This seems an insuperable difficulty in the systems of Drs. Burnet and Woodward; and is equally, though less conspicuously so, in those of Whiston and Buffon.

EARTH-NUTS, or GROUND-NUTS (*Encycl.*). The roots of the water-hemlock, a poisonous plant which bears some general resemblance to that of the arachis, are sometimes mistaken for the latter. See an instance of this under **POISONS** in this SUPPLEMENT.

EAR-WAX, or CERUMEN (*Encycl.*). Citizens Fourcroy and Vauquelin have analysed the ear-wax, and found that it consists of the following substances. 1. Of an oily matter, more resembling the fat which is contained in the gall than any other animal fat. 2. Of an albuminous animal substance. 3. Of a colouring principle, which, by its bitter taste and its close combination with fat, comes near to the colouring principle of the bile.

EASTBOURN, a town in Suffex, noted for plenty of the birds called wheatears, and as a place of resort for bathing. It is seated near the English Channel, 15 miles E.S.E. of Lewes, and 65 S.E. of London.

EAST-LOOE, a mean borough in Cornwall; 16 miles W. of Plymouth; 232 from London.

EASTON, a town of Pennsylvania, capital of the county of Northampton, seated at the confluence of the Leigh and Delaware, 46 miles N. by W. of Philadelphia. Long. 75. 17. W. Lat. 40 21. N.

EASTONNESS, the most easterly cape on the coast of Suffolk, and the N. point of Southwold Bay.

EAU-DE-LUCE (*Encycl.*), is prepared in the following manner: ten or twelve grains of white soap are dissolved in four ounces of rectified spirit of wine; after which the solution is strained. A dram of rectified oil of amber is then added, and the whole filtrated: with this solution should be mixed such a proportion of the strongest volatile spirit of sal-ammoniac, in a crystal glass bottle, as will, when sufficiently shaken, produce a beautiful milk-white liquor. If a kind of cream should settle on the surface, it will be requisite to add a small quantity of the spirituous solution of soap.—Those who may wish to have this liquor perfumed may employ lavender or Hungary water instead of the spirit of wine.

This composition is, however, seldom obtained in a genuine state when purchased at the shops. Its use, as an external remedy, is very extensive; for it has not only been employed for curing the bites of vipers, wasps, bees, gnats, ants, and other insects, but also for burns, and even the bite of a mad dog, though not always with uniform success. Besides, it affords one of the safest stimulants in cases of suffocation from mephitic vapours, and in that state of apoplexy which is termed *serous*, as likewise after excessive intoxication, and in all those paralytic complaints where the vessels of the skin, or the muscular fibre, require to be excited into action. Nevertheless, it ought to be used with due precaution.

Mr. Nicholson, in his Journal, has related the following experiments, made to procure this liquid. He considers *mastic* as a principal ingredient, and the great secret by which the *milkins* has been communicated to it.

One dram of the rectified oil of amber was dissolved in four ounces of the strongest ardent spirit of the shops; its specific gravity being .840 at 60 degrees of Fahrenheit. A portion of the clear spirit was poured upon a larger quantity of fine powdered mastic than it was judged could be taken up. This was occasionally agitated without heat; by which means the gum resin was for the most part gradually dissolved. One part of the oily solution was poured into a phial, and to this was added one part of the solution of mastic. No opacity or other change appeared. Four parts of strong caustic volatile alkali were then poured in, and immediately shaken. The fluid was of a dense opaque white colour, affording a slight ruddy tinge when the light was seen through a thin portion of it. In a second mixture, four parts of the alkali were added to one of the solution of mastic; it appeared of a less dense and more yellowish white than the former mixture. More of the gum resinous solution was then poured in; but it still appeared less opaque than that mixture. It was ruddy by transmitted light. The last experiment was repeated with the oily solution instead of that of mastic. The white was much less dense than either of the foregoing compounds, and the requisite opacity was not given by augmenting the dose of the oily solution. No ruddiness nor other remarkable appearance was seen by transmitted light. These mixtures were left at repose for two days; no separation appeared in either of the compounds containing mastic; the compound consisting of the

oily solution and alkali became paler by the separation of a cream at the top.

It appears, therefore, that the first of these three mixtures, subject to variation of the quantity of its ingredients, and the odorant additions which may be made, is a good eau-de-luce.

In a subsequent number of the same journal, we have the following recipe by one of the author's correspondents, who had often proved its value by experience. "Digest ten or twelve grains of the whitest pieces of mastic, selected for this purpose, and powdered, in two ounces of alcohol; and, when nearly dissolved, add twenty grains of elemi (see *AMYRIS*, *Encycl.*). When both the resins are dissolved, add ten or fifteen drops of rectified oil of amber, and fifteen or twenty of essence of bergamot; shake the whole well together, and let the fæces subside. The solution will be of a pale amber colour. It is to be added, in very small portions, to the best aqua ammoniac puræ, until it assumes a milky whiteness, shaking the phial well after each addition, as directed by Macquer. The strength and causticity of the ammoniac are of most essential consequence. If, upon the addition of the first drop or two of the tincture, a dense opaque coagulated precipitate is formed, not much unlike that which appears on dropping a solution of silver into water slightly impregnated with common salt, it is too strong, and must be diluted with alcohol. A considerable proportion of the tincture, perhaps one to four, ought to be requisite to give the liquor the proper degree of opacity."

EAUSE, an ancient town of France, in the department of Gers, 17 miles S.W. of Condon. Long. 10. 10. E. Lat. 43. 51. N.

EBENEZER, a town of the United States, in Georgia, situate on the Savannah, 25 miles N.N.W. of Savannah. Long. 81. 22. W. Lat. 32. 28. N.

EBENFURTH, a town of the archduchy of Austria, built by the Knights Templars, on the Leyta; 18 miles S. of Vienna.

EEBERBACH, a town of Germany, in the palatinate of the Rhine, remarkable for its wine. It is seated on the Neckar, 10 miles N.E. of Heidelberg. Long. 8. 56. E. Lat. 49. 26. N.

EEBERBERG, a castle of Germany, in the palatinate of the Rhine, seated at the confluence of the Nahe and Alsen, eight miles S.W. of Creutznach. Long. 7. 52. E. Lat. 49. 38. N.

EEBERSTEIN, a district and castle of Suabia, subject to the margrave of Baden. The castle is the chief place, six miles S.E. of Baden. Long. 8. 20. E. Lat. 48. 46. N.

EEBERSTEIN, a town of France, in the department of Lower Rhine, eight miles S.W. of Strasbourg. Long. 7. 46. E. Lat. 48. 29. N.

EEBERVILLE, a town of France, in the department of Puy-de-Dome, with a late rich Benedictine abbey. It is seated on the Scioule, eight miles N.E. of Riom. Long. 3. 15. E. Lat. 45. 59. N.

EBULLITION, the same with **BOILING**. The word is also used in a synonymous sense with **EFFERVESCENCE**.

EECLEFECHAN, a village in Dumfriesshire, noted for its great monthly market for cattle. It is 10 miles S.E. of Dumfries.

ECCLESAL, a town in Staffordshire, with a market on Friday. It is seated on a branch of the river Sow, and the bishop of Lichfield and Coventry has a castle here. It is six miles N.W. of Stafford and 143 of London. Long. 2. 9. W. Lat. 53. 2. N.

ECHTERNACH, a town of Luxemburg, on the river Sout, in a valley surrounded by mountains, 18 miles N.E. of Luxemburg. Long. 6. 33. E. Lat. 49. 50. N.

ECKEREN, a village of Brabant, five miles N. of Bra-

bant. A battle was fought here in 1703, between the French and the allies.

ECYA, or EXIA, an episcopal town of Spain, in Andalusia. It contains 20 convents, and about 9,000 inhabitants, whose principal trade is in wool and hemp. It is seated on the Xenil, 28 miles S.W. of Cordova. Long. 4. 27. W. Lat. 37. 39. N.

EDAM, a town of North Holland, famous for its red-rind cheeses; seated on the Zuider-Zee, 20 miles N. by E. of Amsterdam. Long. 4. 58. E. Lat. 52. 32. N.

EDDYSTONE, the name of some rocks in the English Channel, which cause variety of contrary sets of the tide or current in their vicinity. They are situate S.S.W. from the middle of Plymouth Sound, at the distance of 14 miles. They are almost in the line which joins the Start and the Lizard Points, and their situation with regard to the Atlantic is such, that all the heavy seas from the S.W. come uncontrolled upon the Eddystone rocks, and break over them with the utmost fury. On the principal rock (for the rest are under water) Mr. Winifley, in 1696, undertook to build a lighthouse; and he completed it in 1700. This architect was so certain of the stability of this structure, that he declared it to be his wish to be in it during the most tremendous storm. Unfortunately he had his wish: it was destroyed in the dreadful storm, November 27, 1703, when he perished in it. In 1709, another built of wood, but on a different construction, was erected by Mr. Rudyard, which was consumed by fire in 1755. Another, of stone, was begun by Mr. Smeaton, on April 2, 1757, and finished August 4, 1759. The rock, which slopes towards the S.W. is cut into horizontal steps, into which are dove-tailed, and united by a strong cement, Portland stone, and granite. The whole, to the height of 35 feet from the foundation, is a solid of stones, engrafted into each other, and united by every means of additional strength. The building has four rooms, one over the other, and at the top a gallery and lantern. The stone floors are flat above, but concave beneath, and are kept from pressing against the sides of the building by a chain let into the walls. It is nearly 80 feet high, and since its completion has been assailed by the fury of the elements, without suffering the smallest injury. Its distance from the Ram Head, the nearest point of land, is 12 miles. Long. 4. 24. W. Lat. 50. 8. N.

EDEN, a river which rises in Westmoreland, on the confines of Yorkshire, and running N. by Appleby and Carlisle, falls into Solway Frith.

EDENTON, a town of North Carolina, on the N. side of Albemarle Sound, with an episcopal church. It is the capital of the Chowan County, and 78 miles S. by W. of Willsborough. Long. 76. 40. W. Lat. 35. 58. N.

EDGHILL, a village in Warwickshire, where the first battle was fought between Charles I. and the parliament, in 1642. It is 14 miles S. of Warwick.

EDGWARE, a town in Middlesex, with a market on Thursday, eight miles N.W. of London. Long. 0. 14. W. Lat. 51. 37. N.

EDIKOFEN, a town of Germany, in the palatinate of the Rhine, near which a battle was fought between the French and Prussians on July 12, 1794; the contest was long and bloody, and the victory doubtful; but the battle was renewed the next day, and terminated in favour of the French.

EDINBURGH (*Encycl.*). As many of our readers may feel a satisfaction in being acquainted with the manner in which medical education is conducted in a seminary so much celebrated as that of Edinburgh, we here insert it, from vol. VI. of the Medical and Physical Journal.

The university of Edinburgh was founded by James the Fifth of Scotland, about the year 1581, and is denominated in

all official writings, *Academia Jacobi Sexti, Regis Scotorum quæ Edinburgi est*. It consists of a principal and professors, who have small salaries, and all of them, except the regius professors, are appointed by the town-council of Edinburgh, who have likewise the power of instituting new professorships when they shall see occasion. The principal, with the whole body of professors, form the *Senatus Academicus*, which enacts laws for the regulation of the college, and settles all matters relating thereto. Degrees are confirmed, at certain periods, by the principal with the consent and approbation of this body. There is an endowment of a few pounds per annum for a small and limited number of bursars, but there are no fellows.

Most of the professors, and the whole number of students, live in the town; the latter wear no particular drefs, are subject to no college laws, and may attend the lectures at such times only as they please. There is indeed a small fine for absence or inattention, at one or two of the junior classes, as the Latin and Greek. The college exercises, besides those of construing, translating, or demonstrating, at the Latin, Greek, or mathematical classes, are writing occasional essays on subjects connected with their studies; at the logic, the higher Latin and Greek classes, the divinity, and of late years at the moral philosophy. The only class, we believe, at which there is any examination on what has been previously heard, is the logic. It is rather to be lamented that there are not more frequent opportunities of competition in the various classes of this university; and it is a circumstance which must naturally excite considerable wonder among those who are informed of it, that there is not a single medal or prize of any kind ever offered for the best essay on any subject, whether literary or philosophical. When it is considered how great is the inducement afforded to industry by an honorary reward of this kind, how trifling is the expence attending it, and how very many there are of distinguished rank, fortune, and reputation, who have had the elements, if not the whole of their education, at this university, it is extremely singular that no endowment of this nature has ever been made. The professors themselves, who amount to a considerable number, and are highly respectable for their learning and talents, might, by a very small individual contribution, raise a sufficient sum annually for defraying the expence of a small number of prize medals.

The professorships in the university of Edinburgh are divided into four faculties, viz. the *faculty of theology*, of *law*, of *medicine*, and of *arts*; and the whole number of professors amounts to about twenty-four.

In the *faculty of theology* is comprised divinity, church history, Hebrew and oriental languages:

In the *faculty of law*, civil law, law of nature and nations, universal history, and Scott's law:

In the *faculty of medicine*, anatomy and surgery, practice of physic, chemistry, materia medica, theory of physic, botany, and midwifery.

In the *faculty of arts*, Latin or humanity (literæ humaniores), Greek, mathematics, logic, moral philosophy, natural philosophy, rhetoric and belles-lettres, natural history, practical astronomy, agriculture.

Till near the revolution there were no medical professors at this university, and even till the year 1720 they were merely titular. About that period the late celebrated Professor Monro commenced his anatomical lectures, and from that we may date the formation of the medical school in Edinburgh, which has gradually arisen to a degree of celebrity unequalled by any other in Europe.

From the above enumeration, it appears that the medical professorships are seven in number. That of midwifery is not however on the same footing with the others, as the pro-

feſſor has no ſhare in the medical examinations, nor is it neceſſary for a ſtudent to attend this claſs before he is eligible to a medical degree.

The lectures commence in the latter end of October, with the exception of midwifery, of which there are three courſes in the year, viz. two in the winter and one in the ſummer, and laſt until the latter end of April or the beginning of May. The botanical lectures are only given in the ſummer ſeaſon, during the months of May, June, and July, at the Botanical Garden, a ſhort diſtance from Edinburgh. The preſent profeſſor of chemistry has for ſome time given a ſummer courſe of lectures which laſts three months.

The firſt few lectures in the ſeaſon are always occupied with the hiſtory of the ſcience, by way of introduction: and as the ſacraments of the church of Scotland, which occur twice a year, give an interruption to them for a week in the beginning of November, the particular buſineſs of the courſe is not entered upon till about the 10th or 11th of that month. The lectures are an hour each in length, except the anatomical, which is an hour and a half at leaſt. They are given on every week-day except Saturday, and on that day ſome of the profeſſors have occaſion to lecture during a part of the ſeaſon, in order to get through the buſineſs of the courſe.

The following are the names of the preſent profeſſors, and the hours at which they lecture:

Dr. Monro	{ anatomy	- - - - -	1 P. M.
Dr. Monro, jun.			
Dr. Gregory	- - practice of medicine	- - -	9 A. M.
Dr. Hope	- - chemistry	- - -	10 A. M.
Dr. Duncan	- - theory or inſtitutes of med.	- - -	11 A. M.
Dr. Home	{ materia medica	- - -	8 A. M.
Dr. Home, jun.			
Dr. Rutherford	- botany	- - -	8 A. M.
Dr. Hamilton	{ midwifery	- { in winter	3 P. M.
Dr. Hamilton, jun.		- { in ſummer	10 A. M.

Any perſon who fees a claſs may attend the lectures; it is neceſſary, however, to be afterwards enrolled in the college books at the matriculation, to be able to procure any official document of academical education, and to have acceſs to the valuable collection of books of which the college library conſiſts. This noble library is enriched with a copy of every book which is entered at Stationers' Hall, and is aided by a ſmall ſum paid by each ſtudent at his matriculation. The books may be procured, to a limited number, by ſtudents, on their depoſiting the value with the librarian, who returns it on receiving the book.

The whole number of ſtudents at the univerſity is from 1000 to 1300, of whom between four and five hundred are medical. The profeſſor of anatomy has never fewer than three hundred attending him, and ſometimes many more. The other claſſes, particularly thoſe of the practice of medicine and chemistry, are alſo well attended.

To the profeſſor of anatomy belongs a very capital collection of preparations, which may be inſpected, by the ſtudents in the lecture-room, or in ſome cloſets adjoining it, in the courſe of the ſeaſon. He is always able to provide a ſufficient number of ſubjects for public demonſtration, but there are no opportunities of private diſſection afforded in the college.

Students who attend the midwifery claſs have the advantage of practice at the lying-in hospital. Connected with the medical education of the college is the attendance at the royal infirmary, which is a building capable of containing above two hundred patients, and ſupported principally by voluntary contributions. The medical and ſurgical patients are kept in different wards, and from the medical are ſeleſted about fifteen males, and as many females, with the moſt intereſting complaints, who are put into ſeparate wards, denominated *clinical*, and are attended by a medical profeſſor of the college, of whom there are generally four who take the duty alternately. The profeſſional buſineſs of the infirmary is performed by two ordinary phyſicians, appointed for a permanence, with ſalaries; two ſurgeons*, a clinical phyſician, two phyſicians' clerks, a houſe ſurgeon, and two clinical phyſicians' clerks. The phyſicians' clerks and houſe ſurgeon are appointed by the managers, and reſide in the hospital; the clinical phyſicians' clerks are appointed by the clinical phyſician for the time of his attendance, and do not reſide. The patients are ſeen by the phyſician or ſurgeon having the care of them, every day, except Sunday, at twelve o'clock.

The manner in which the buſineſs of the hospital is conducted, reflects much credit on all concerned in it, and is extremely conducive to the improvement of the ſtudent. On the admission of any patient, whether ſurgical or medical, the houſe ſurgeon or phyſicians' clerk, take down an accurate account of the ſymptoms, and hiſtory of the complaint, in a book for the purpoſe, in which are inſerted the daily progreſs and treatment, dictated by the attending ſurgeon or phyſician. Theſe books are, at certain times of the day, left in a particular room for the inſpection of the ſtudent; and as they are liable to the ſeverity of criticiſm, both as to ſtyle and accuracy, it is the intereſt of all parties that they ſhould be correct. The ſurgical caſes of the hospital form the baſis of a valuable courſe of lectures, given twice a week during the winter months, by Mr. Ruſſell.

Patients admitted into the clinical wards are the peculiar objects of attention. An accurate hiſtory of their complaints is taken by one of the clerks on their admission, and a very full report of the ſtate of the patient, with the progreſs and treatment of the diſeaſe, is every day dictated by the clinical phyſician, who alſo gives lectures on theſe caſes at the college every Tueſday and Friday, at five o'clock. There are two clinical phyſicians in winter and one in ſummer, each of them officiating in this ſituation three months.

The fee for the clinical, and each courſe of medical lectures at the college, is three guineas, with a ſmall ſum to the janitor and ſervants. Every part of the hospital, whether medical, ſurgical, or clinical, is open to the ſtudent for three guineas annually; and this fee, as well as that for the clinical lectures, is, we believe, leſſened after a certain attendance. The ſtudents are at liberty to viſit any part of the hospital, at any time of the day, to make their perſonal obſervations on the ſtate of the patients, and compare the reports dictated by the phyſicians or ſurgeons with the appearances of the diſeaſe.

Before any gentleman can be examined for a medical degree in Edinburgh, he muſt bring forward documents of hav-

* The care of the ſurgical patients of the hospital formerly belonged to the whole college of ſurgeons, who took the duty by rotation, for two months at a time; the ſucceſſor acting as an aſſiſtant until it became his turn to officiate. Dr. Gregory, while preſident of the college of phyſicians in Edinburgh, publiſhed an addreſs to the managers on the ſubject of the ſurgical attendance of the infirmary, and ſucceeded ſo far as to induce them to make material alterations in it. There are now on the eſtabliſhment ſix hospital ſurgeons, who are appointed for a permanence, with ſix aſſiſtant ſurgeons under them. Two of theſe ſurgeons act for two years at a time, and divide the patients. There is alſo a certain number of diſpenſers appointed by the ſurgeons.

ing studied medicine three years, at that or some other university. The testimonial of that part of his education which he received in Edinburgh, is given him from the records of the university by the secretary. As it may be acceptable to some of our readers to be informed of the regulations with regard to medical degrees in Edinburgh, we shall present them with nearly a literal translation of the statutes on this subject, known by the name of *Statuta Solemnia*.

Statutes of the university of Edinburgh on the subject of medical degrees; proposed by the faculty of medicine, and enacted by the senate.

1. No one shall be admitted to the degree of doctor of medicine, except on the 24th of June and the 12th of September, or the days immediately subsequent.

2. No one shall be admitted into the number of candidates unless he shall have, for the space of three years, studied, in this or some other university, medicine and the branches comprised in it, to wit, *anatomy and surgery, chemistry, botany, materia medica, and pharmacy, and the theory and practice of medicine*, and unless he shall have attended the clinical lectures given by the professors of medicine, on the cases in the infirmary.

3. Three months at least before the above-mentioned days, every one desirous of the honours of medicine, must deliver a *medical inaugural dissertation* to one of the medical professors, who is to read it over, amend it if necessary, and annex to it, in writing, his *perlegi*, or certificate of having read it, with the day on which it was received.

4. On or before the 20th of April, or July, he must communicate his with to the dean of the faculty of medicine*; and at the same time deliver to him his inaugural dissertation (with the certificate of the professor who has read it annexed), to be subjected to the opinion of the faculty of medicine, in order that they may, by this specimen, as well as by a private examination, be acquainted with his progress in learning, particularly in the science of medicine, before they admit him into the number of candidates.

5. On the 18th of May, or the 6th of August, the candidates shall be examined by the two medical professors before the faculty of medicine, in the various branches of medical science above enumerated.

6. Should the candidate be approved, an aphorism of Hippocrates shall be proposed to him by one of the medical professors, and a medical question by another. The former, explained and illustrated by a commentary; the latter, with an answer supported by proper arguments, he shall deliver on the 28th of May, or the 16th of August, to the professors who proposed them; and he shall defend his commentary and answer on the 30th of May, or the 18th of August, before the faculty of medicine.

7. Should the candidate be thus far approved, there shall be delivered to him by two professors, two histories of diseases, with questions annexed, that he may illustrate and answer them in writing. The cases thus illustrated, together with the answers, he shall deliver to the professors proposing them on the 12th of June or the 1st of September, and shall defend them before the faculty of medicine on the 15th of June or the 3d of September.

8. If the candidate be approved after the first trial on the 18th of May, or the 6th of August, he is at liberty to print his inaugural dissertation, and must deliver six correct copies of it (wanting the page which expresses the title and the authority of the university) to the dean of the faculty of medicine, on the 15th of June, or the 3d of September.

9. Should the candidate be a third time approved by the faculty of medicine, the dean of the faculty shall report to the senate every thing which has been done, and by their authority and approbation, he shall be ordered to publish and defend it, on the 24th of June or the 12th of September. He shall then, if agreeable to the senate, receive in the usual way, the reward of his studies and labour, the degree of doctor of medicine.

10. The faculty of medicine shall always meet at the college on the above-mentioned days at nine o'clock in the morning.

11. All the aforesaid examinations and exercises shall be in the Latin language.

No examinations can be conducted with more candour than those in Edinburgh. Questions are never asked with a view to puzzle or perplex, nor are any ever proposed which a student should not be able to answer. On the other hand, the examinations are not merely formal, as the professors never hesitate in rejecting a man, whom they do not conceive properly qualified. The principal examination is that mentioned as a private one at No. 4 of the Statuta Solemnia; it is held at the house of one of the professors; and is attended by the whole of the faculty of medicine as examiners. The gentleman at whose house the meeting is held, begins by an examination of the general functions of the body, and then selects a particular viscus, of the structure and uses of which he requires an explanation. The others confine themselves to practical and pathological questions on the diseases of this organ, in which the prognosis, diagnosis, treatment, and nature of the remedies employed in the cure, come under review.

The other examinations are in the college hall. The degree is conferred by the principal, after an oath taken by each graduate to practise his profession in a just and honourable way. The diplomas are signed by the principal and the whole of the members of the *Senatus Academicus*.

The graduation fees to the college amount to between thirteen and fourteen pounds, and are paid to the proper officer immediately after the examination at No. 5 of the statutes.

A gentleman who has passed this examination may, if he please, defer taking his degree for some time, and resume his exercises at the stage at which they were left off.

Having given this general account of the mode in which medical education is conducted in the college of Edinburgh, the same writer transmits the following supplementary observations on the subject. (Med. and Ph. Jour. No. 35.)

The opportunities afforded at this university of prosecuting the study of medicine are not confined to the college. Private lectures are also given in anatomy, surgery, physiology, and chemistry, by men of merit and eminence, which are of considerable advantage to the student, particularly in the study of anatomy. This science is the only one in which Edinburgh has not arrived at a considerable degree of eminence, and it is in a great measure owing to the difficulty there has been in procuring a sufficient number of subjects for private dissection. The exertions of the private teachers have, however, in some measure, done away this disadvantage, and the more frequent opportunities of prosecuting practical anatomy which are now enjoyed, must necessarily be of material service to the university. Anatomy cannot be learnt from lectures alone, for however perspicuous the demonstrations may be which accompany them, the ideas which they produce must remain in some measure indistinct and imperfect without the aid of dissection, and the more so when they are given to a very large number of students at one time, as is the case in Edinburgh.

* This is generally, if not always, the youngest professor of that faculty.

It is of extreme importance in the study of any science, that the first rudiments should be correct and distinct. Imperfect ideas are easily acquired, but they greatly retard the after-progress, and are sometimes never entirely removed. If there is, therefore, a desideratum in the medical education of Edinburgh, it is, that more opportunities should be afforded to the student of prosecuting the study of anatomy. There are certainly many obstacles in the way of procuring subjects sufficient to enable the greater number of medical students to cultivate practical anatomy, and it is not improbable that the popular prejudices against dissection, and the more limited opportunities of obtaining bodies in Edinburgh than in London, will make it always inferior to the latter as an anatomical school. The societies which are instituted in Edinburgh for discussing medicine and medical philosophy have a considerable tendency to encourage the desirable habits of study and investigation. It must be admitted, however, that they have their disadvantages; for to young men, who have just assumed the right of thinking for themselves, without having obtained that information which is necessary as the foundation of their opinions, they frequently hold out a dangerous and successful allurements, which diverts them from the more substantial parts of their studies, renders them disputatious, and encourages habits of self-complacency and conceit. It is, perhaps, a good deal owing to the effects of societies in general, that the students of Edinburgh obtained the character from Dr. Franklin of being, with lawyers, particularly fond of dispute. Upon the whole, however, it appears, that the more respectable of the medical societies are conducive to professional improvement, if they are only regarded as subservient to the other parts of education, if they are not attended too early, and if the student does not, as is too frequently the case, take a part in the discussion beyond his information.

The *royal medical*, and the *royal physical*, are two principal societies devoted to subjects connected with medicine. The former stands highest in point of general respectability and importance, and has, in the list of its members, many of the most distinguished medical characters in Europe. It was here, as Dr. Gregory remarks in his lectures, that the Boerhaavian doctrines were first freely discussed, and such objections urged against their solidity, as gradually led to their abandonment. The members assume the full right of freedom of discussion on any opinions, by whatever authorities they may be supported, and are extremely jealous of the smallest endeavour, on the part of the professors, to control them. During the time that the celebrated doctrines of Brown first began to be canvassed, the warmth of debate was carried on so far, as to render it necessary to pass a law (which still exists) to enact, that any gentleman who should challenge another, on account of any thing which might take place during debate, should be expelled the society.

The Royal Medical Society was instituted in the year 1737, and obtained a charter of corporation in 1778. It is governed by four presidents, and by committees chosen annually from the members by ballot. The meetings are held once a-week, and last from 7 in the evening till 12. An essay on a medical case, and a dissertation on some subject connected with medicine (which are written by the ordinary members in rotation, and are termed a set of papers), are discussed every evening, and not more than two sets of those papers are expected from any gentleman during the time of his being in the society. They are circulated among the members before discussion, and are copied into proper books, which are open to their inspection in the library. Fines are exacted for absence either during the whole or part of the evening, and these are so considerable as to enforce a pretty

punctual attendance. The admission fee is five guineas; one guinea is paid in the beginning of the second year of attendance, and half a guinea in the beginning of the third, after which no further sum is required. A member, after having written two sets of papers, and completed two sessions in the society, becomes extraordinary, and is then freed from fines or contributions.

This society is possessed of a very valuable library and philosophical apparatus, which are under excellent regulation. Periodical publications and new works lie a certain time upon the library table, for the use of the members, before they are put into the body of the library.

There are several circumstances which have tended to establish the reputation of Edinburgh, and to make it a very general resort for medical students. Two or three of those it may not be improper to mention.

The celebrity of its professors, without doubt, brought it first into notice, and on this, its estimation in the eyes of Europe must still depend. The establishment of professors in Edinburgh has a powerful tendency to preserve that zeal and activity in the prosecution of the subjects which they teach, so necessary to the advancement of science and the increase of personal reputation. The salaries are very small, their emoluments must therefore principally depend upon the manner in which their lectures are attended, and this again on the estimation in which they are held. In Edinburgh, too, the practice of a physician is very much limited. Lecturing is not, therefore, as is often the case in London, employed as an introduction merely to public notice, but is regarded as a profession to which a man feels it his interest to direct all his abilities and attention.

Without having the most distant intention of making any application on the subject, we may be allowed to observe, that, a more respectable phalanx of medical men could scarcely be brought together, than filled the professional chairs of this university a few years ago. Any one conversant with its history, must know that weallude to the period at which Dr. Calten, Dr. Black, Dr. Gregory, Dr. Hope, Dr. Monro, and Dr. Home, were all of them at one time engaged in teaching the different branches of medical science. It is extremely difficult to point out that mode of electing professors, which is, most likely to ensure their being properly qualified for their office.

The members of a town-council do not appear to be the men best adapted for this purpose, and yet it is with them, that the nomination rests. Hitherto, there has been little ground of complaint; it may easily however be seen, that the utmost circumspection is necessary to preserve the respectability of the professional chairs in the eyes of Europe, and that the system which has been adopted of late years, of appointing the son as the successor or colleague of his father, if carried too far, will be highly injurious to the interests of the university.

The habits of life, both of the students and the inhabitants in general of Edinburgh, are very favourable to the steady pursuit of scientific knowledge. The students are not men of fortune, who come to the university for the purpose of *loazing away* two or three years for the sake of form or fashion, but are such as depend for their success on their perseverance, assiduity, and attention in the pursuits to which they are devoted. Enquiry is encouraged by the professors, excited by the easy intercourse which takes place among the students, and readily gratified by the facility with which books can be procured, whether from the college-library or that of the royal medical society. The desire of distinction among themselves, and the wish to come off with credit on an application for a degree, have also a very considerable and salutary influence upon the students.

The inhabitants of Edinburgh are, in general, distinguished for information and propriety of behaviour, which may be attributed to a variety of causes. Learned and literary men, particularly those connected with the college, are held in great estimation, and are received with cordiality into the highest circles. By far the most numerous class of the respectable inhabitants are in the professions; and commerce, which sometimes suddenly raises ignorant and ill-educated men to affluence, has scarcely any place in the Scottish capital. These circumstances must be without some effect upon the minds of young men who go thither for the purpose of improvement.

The lectures themselves are more comprehensive than those which, as far as we know, are delivered in any other university in Europe; and the infirmary, as mentioned in a former place, is under regulations, which render it productive of much advantage to the student.

The estimation in which Edinburgh is held as a school of medicine, is sufficiently marked by the general resort of students to it from every part of Europe. Few medical men, who can boast of a regular course of study, have not enjoyed the advantages of this school; and by much the greater number of the most respectable physicians of this island, have graduated in Edinburgh. It may hardly be thought necessary to make any observations on the respectability of Edinburgh degrees, after the detail which we have given, and the general estimation in which they are held with the public; we think it proper however to observe, that, to the disgrace of an honourable profession, and of an enlightened nation, which ought, on account of its usefulness, to preserve its respectability, the right of practising medicine is at this time to be purchased at a Scotch university without study, attendance, or examination; simply by a certificate of fitness from two physicians, who, it is to be feared, too often sign it from courtesy, without being adequately informed of the education or acquirements of the person whom they recommend. It ought therefore to be recollected by those who, from this circumstance, depreciate the value of Scotch degrees, that it is unfair and uncandid to class the university of St. Andrew's with that of Edinburgh, where the eligibility to examination for a degree can only be obtained by three years' regular study, and where the examination itself is well adapted to discover how far the student has availed himself of the opportunities he has enjoyed.

It seems highly preposterous, that a qualification to practise a liberal profession, like that of medicine, which has not only its general character for learning to support, but which also requires no small share of study and application to become acquainted with its principles, should be able to be purchased by any one who chooses to be at the expence of it; for though it be admitted, that the certificate of qualification be in some measure a check upon the introduction of any improper persons to the honours of medicine, yet is it to be imagined, that medical men cannot occasionally be found, who will so far forget their own honour and the honour of their profession, as to recommend men very ill adapted to support its credit and respectability? In the professions of law and divinity, it is required that a man should spend a certain time in the study of his profession before he is admitted to practise it; or, at least, that he should be of so long a standing as to give him a full opportunity of having turned his attention to it; and even then a certificate of fitness is required previous to admission. If such be proper or necessary in the professions which we have mentioned, is it not doubly so in that of medicine, where the health or the life of individuals depend upon the knowledge and judgment of one man, and where there is often no time for looking into sources of information, or endeavouring to supply a deficient knowledge of the subject? The evil is

serious; and it is the duty of every good man, who wishes well to the profession of medicine and to the public, to do his endeavours to remedy it. For though some individual instances may occur, in which a man may be possessed of every qualification necessary for a physician, and would be much inconvenienced by not having a medical degree without the loss of time incurred by an attendance at an university for the purpose of obtaining it, yet the possibility of such an occurrence ought not to prevent any measure of universal public and professional advantage. It would not be thought sufficient for a person in a subordinate part of the law, who had been all his life engaged in the practice of his profession, to say, that he expected to be once admitted to the bar, because he conceived himself qualified to practise as a counsel. He would be expected to pursue the same course, as if he had been just entering upon the study of the law, however inconvenient might be the delay. And it does not appear particularly unreasonable, that when a profession is either entered upon or changed, a sacrifice of two or three years should be made, in order to obtain a qualification to practise it, though it may occasionally be attended with some personal inconvenience.

The Royal College of Physicians of London seem perfectly convinced of the propriety of requiring a certain academical attendance from every one, previous to examination for the liberty of practising in the metropolis; when they make it necessary for such as present themselves, to produce documents of having studied two years at the same university where they graduated. This by-law appears to be founded upon the most judicious principles, and does credit to the judgment of that learned body. The latter part of it is clearly with a view to prevent those from applying for admission as licentiates, who were rejected on their examination for a degree at the university where they were educated, and afterwards procured one by purchase.

The Royal College of Physicians of Edinburgh have a defect in their charter, which prevents their being able to adopt the same salutary regulations with that of London, on the mode of admitting licentiates or fellows. By their charter it is enacted, that not only graduates of Edinburgh, but of any other Scotch university, shall be admitted by right a licentiate of the college, without examination; and by the constitution of the college, a licentiate, after remaining twelve months in that probationary state, is admitted a fellow as a matter of course.

That Edinburgh graduates should be admitted without examination into the college of physicians, is not improper, because the heads of this college are members of the faculty of medicine of the university, and the persons who on examination thought him duly qualified to practise medicine. But, that any person who has purchased a St. Andrew's degree, should be able to claim the same privilege, completely does away any idea of honour from a connection with that body. The absurdity of the clause above mentioned, more clearly appears from a case which is not only possible, but may at any time occur. A student may be thought unqualified for the honour of a degree in Edinburgh, and may be rejected. He may afterwards procure a degree from St. Andrew's, and insist upon admission into the college of physicians of Edinburgh, though he will be there associated with the very men who thought him unworthy of a degree from the university. Thus it appears, that the degree of doctor from the university is more honourable than that of fellow of the royal college of physicians, a circumstance far from being generally known, though it may be very fairly inferred from the respectable evidence of Dr. Gregory, who made the observation to which we alluded above, when actually president of the college.

On a comparison of the advantages afforded by Edinburgh and the English universities, in the study of medicine, there can be no hesitation in preferring the former. As an argument in favour of Oxford and Cambridge, much stress has been laid upon the length of time which it is necessary to be connected with those universities, before the degree of doctor can be obtained. But in this point of view, the balance must be on the side of Edinburgh, for a great part of the attendance at the English universities is merely nominal, half terms only being sufficient before taking the degree of bachelor of medicine; and from that time until the period at which the degree of doctor is conferred, no attendance is necessary at all. Does the period of absolute attendance, therefore, which is necessary previous to taking a doctor's degree, predominate in Edinburgh, or in the English universities? Much of the advantages derived from a place of education, necessarily depends upon the time and punctuality of attendance; and this applies more strongly in medicine, than perhaps any other profession. When we therefore consider that the period of *actual attendance* in Edinburgh is equal to that which is requisite at either of the English universities; and when we also recollect, that during the whole of that attendance, the time is occupied in the proper business of the profession, little doubt can exist on the comparative merits of those seminaries as schools of medicine. It is usual, and indeed necessary, that gentlemen educated to physic at either of the English universities, should prosecute the study of their profession elsewhere; but is it not a circumstance of a most singular nature, that the only advantage in medicine from those illustrious seminaries, is the obtaining a degree? and that the previous acquirements which are necessary to qualify a man to practise with honour to himself, or advantage to the world, must be made in another place?

Establishment for the poor.—There has been opened at Edinburgh, an house for the employment and relief of the poor. Notice had been publicly given that mendicity would no longer be permitted in that city; there being both employment and the means of subsistence in the house, for every beggar and destitute person who was disposed to work. They were also informed that they would receive the full amount of their earnings, with such additional gratuitous assistance, as might, in the whole, be equal to their decent maintenance.

From the 22d of January, 1801, to the 16th of March, ninety persons of different ages were admitted into the house. The number has since been considerably increased. Of these, few, comparatively speaking, were of the ordinary class of beggars; they, in general, fled upon the alarm; and retired to quieter situations, in London, and other municipalities, where similar measures of prudential charity have not been adopted. Of those distressed persons who have been admitted into the house, almost all have been received on their own application; many of them widows advanced in life, whom the high price of provisions, and the want of occupation, had compelled to dispose of the greater part of their furniture and clothes, for immediate subsistence;—or young women, who, with characters apparently unimpeached, were exposed to a course of pilfering and prostitution.

It was fixed that they should have the *whole produce of their earnings*; besides they receive *gratis*, a cheap dinner, and two pence a-day each in money. The pecuniary allowance has, for the present, been rendered expedient by the peculiar circumstances of the times, the high price of food, and the state of weakness and indigence to which the poor are reduced. The continuance of that part of the relief, it is to be hoped, will not be universally necessary.

Their earnings are small;—but it is not a small object to be obtained, that such a class of persons should be virtu-

ously and industriously employed; that they should be *earning something*, and acquiring the habit and skill to earn more. They express very generally, and very strongly, their gratitude for the advantages, which they derive from the charity; and look forward to its continuance with eager and solicitous expectation. Only two of them have merited serious reprehension; and they are now dismissed the house, to the advantage and apparent satisfaction of the rest.—Of the ninety persons admitted, seventy-four have been employed in spinning flax,—three in spinning hemp,—and one in spinning wool: all of these have been furnished by the manufacturer with the raw materials, and are paid by him, according to the usual rates, for the quantity they respectively spin.—Besides these, six have been employed in making lace, three in knitting stockings, two in reeling yarn, and assisting in the house, and one (a joiner with five children in great distress for want of work) in mending the spinning-wheels, and in making a variety of little articles for sale.

To occupation, and the means of subsistence, the directors of this excellent charity have added medical advice and aid. Of this department, an eminent physician, Dr. William Farquharson, has taken the direction; the institution being put to no other expence, than that of the wholesale price of the medicines which the poor may require.

The establishment is supported by voluntary contributions, not only of money, but of clothing and spinning-wheels, supplied by public bodies at Edinburgh, as well as by individuals. In consequence of a report made by the Rev. Dr. Baird (*principal of the university* at Edinburgh, and a most active conductor of the charity) the society lately established at Edinburgh, “for encouraging the industry and increasing the comforts of the poor,” has taken this charity under its peculiar patronage and administration; and has added considerably to its funds.

BDNAM, a village near Kelfo, in Roxburghshire, seated on the Tweed. It is the birth-place of the poet Thomson.

EFFINGHAM, a village in Surrey, 12 miles N.E. of Guildford. It was once, according to tradition, a populous town, containing 16 churches. There are, certainly, proofs of its having been a much larger place; for wells and cavities like cellars, have been frequently found in the neighbouring fields and woods; and in the church are some ancient stalls and monuments.

EGG, a fertile little island, one of the Hebrides of Scotland, to the S. of Syke.

EGHAM, a village in Surrey, four miles N.N.W. of Chertsey. Here is a neat almshouse for six men and six women, with a school for the education of 20 boys, founded by Mr. Henry Strobe, in 1706; and another almshouse, for six men and six women, founded by Judge Denham, father of the poet of that name. Near this place is the celebrated Runnymede.

EGLINGEN, a town of Suabia, capital of a lordship of the same name, six miles N. of Dillengen.

GLISAU, an ancient town of Switzerland, in the canton of Zurich, seated on the Rhine, 13 miles N. of Zurich. Long. 8. 30. E. Lat. 47. 33. N.

EGMONT BAY, a bay on the S.W. of the Island of St. John, in the gulf of St. Lawrence. Long. 64. 0. W. Lat. 46. 30. N.

EGMONT ISLAND, a low woody island in the South Pacific Ocean. Long. 138. 30. W. Lat. 19. 20. N.

EGREMONT, a town in Cumberland, with a market on Saturday. It is seated near the Irish Sea, on the river Ehen, over which are two bridges; and on the peak of a hill is a castle. It sent members to parliament in the reign of Ed-

ward I. and is 14 miles S.W. of Cockermonth, and 299 N.W. of London. Long. 3. 35. W. Lat. 54. 32. N.

EGYPTEN, a town of the duchy of Courland, 100 miles S.E. of Mittau. Long. 26. 40. E. Lat. 56. 2. N.

EHIGEN, the name of two small towns of Susbia, the one near the Danube, and the other on the Neckar. They belong to the House of Austria. The former is in long. 9. 45. E. lat. 48. 18. N. and the latter in long. 8. 45. E. lat. 48. 25. N.

EHRENBREITSTEIN, a very ancient fortress, in the electorate of Treves, on the E. bank of the Rhine, opposite Coblenz. It stands on the summit of a stupendous rock, not less than 800 feet above the level of the river, and is thought, when supported by a competent garrison, to be impregnable. It has a communication with Coblenz by subterraneous passages cut out of the solid rock; and is plentifully supplied with water from a well 280 feet deep. In the centre of a large square in this fortress, is placed a cannon, supposed to be the largest in Europe; it was cast in 1528, weighs 300 quintals, and projects a ball of 180 pounds, upwards of 12 miles. The prospect from this castle is majestic, extensive, and variegated; and the stream at its foot is decorated with two small islands, on each of which is a convent. In the vale of Ehrenbreitstein is the old palace of the elector. The fortress surrendered to the French, after a long siege, and a blockade of above a year's continuance, in February 1799.

EHRENFELS, a fortress of Bavaria, in the duchy of Neuburg, which gives name to a lordship. It is 13 miles N.W. of Ratibon.

EJECTION, in Scots law, is the turning out the possessor of any heritable subject by force; and is either *legal* or *illegal*. Legal ejection is where a person having no title to possess, is turned out by the authority of law. Illegal ejection, is one person's violently turning another out of possession without lawful authority.

EILENBURG, or EULENBURG, a town of Upper Saxony, 12 miles N.E. of Leipzig.

EIMBECK, a town of Germany, in the territory of Grubenhagen, 25 miles S. of Hildesheim. Long. 10. 0. E. Lat. 51. 46. N.

EIMEO, one of the Society Isles, in the S. Pacific Ocean, lying near Otaheite. The products of the two islands, and the manners of the people, are much the same. Eimeo has steep rugged hills, running in different directions, leaving large valleys, and gently rising ground about their sides. The hills, though rocky, are generally covered with trees almost to their tops.

EISLEBEN, a town of Upper Saxony, in the county of Mansfeld, famous as the birth-place of Luther. It is five miles E. of Mansfeld.

EISNACH, a town of Thuringia, capital of a district of the same name, with a celebrated college, 36 miles W. of Erfurt. Long. 10. 25. E. Lat. 50. 59. N.

EITHAN, or YTHAN, a river in Aberdeenshire, which crosses that county in a S.E. direction, and falls into the British Ocean at Newburgh.

EKERFORD, a town of Denmark, in the duchy of Sleswick, seated on the Baltic, 12 miles S.E. of Sleswick. Long. 10. 30. E. Lat. 54. 56. N.

ELBA, an island on the coast of Tuscany, remarkable for mines of iron and loadstone, and quarries of marble. It is subject to the Prince of Piombino, under the protection of the King of Naples, who is in possession of Porto-Longone; and the Grand Duke of Tuscany has Porto-Ferrajo.

ELEASSANO, a town of Turkey in Europe, in Albania, 45 miles S.E. of Durazzo. Long. 20. 9. E. Lat. 41. 34. N.

ELBOGEN, a town of Bohemia, capital of a circle of the

same name, with a citadel, on the river Eger, 16 miles N.E. of Egra. Long. 13. 0. E. Lat. 50. 16. N.

ELBURG, a town of the United Provinces, in Guelderland, on the E. coast of the Zuider-Zee, 10 miles N.E. of Harderwick. Long. 5. 50. E. Lat. 52. 30. N.

ELCATIE, a sea-port of Arabia Felix, on the W. coast of the gulf of Perlia, 300 miles S. of Bufohar. Long. 53. 5. E. Lat. 26. 0. N.

ELCHE, a town of Spain, in Valencia, 20 miles S.W. of Alicante. Long. 0. 23. W. Lat. 38. 7. N.

ELECTRICITY, GALVANIC. See GALVANISM in this SUPPLEMENT.

ELECTRICAL DOUBLER, an ingenious and useful invention of Mr. Bennet, well known to electricians, and much improved by Mr. Cavallo. The original instrument would be freed from its principal imperfections, we apprehend, by interposing a plate of air between the three plates of the doubler. Thus, if we stick on one of the plates three very small spheres, made from a capillary glass tube, or from a thread of sealing-wax; the other plate, when laid on, will rest merely on so many points; and there will be scarcely any friction capable of hindering the process of the experiment. Mr. Nicholson's contrivance for expediting the effect of the doubler is very ingenious.

ELECTROPHORUS, a machine, represented in Plate 26, the phenomena of which are somewhat singular. It consists of two plates, A and B, usually of a circular form; though they may be made square, or of the figure of a parallelogram, with more ease, and with equal advantage. At first the under plate was of glass, covered over with sealing-wax; but there is little occasion for being particular either with regard to the substance of the lower plate, or the electric which is put upon it. A metallic plate, however, is perhaps preferable to a wooden one, though the latter will answer the purpose very well. This plate is to be covered with some electric substance. Pure sulphur answers very near as well as the dearer electrics, sealing-wax, gum-lac, &c.; but it hath this bad quality, that, by rubbing it, some exceeding subtle steams are produced, which infect the person's clothes, and even his whole body, with a very disagreeable smell, and will change silver in his pocket to a blackish colour. The upper plate of the electrophorus is a brass plate, or a board or piece of pasteboard covered with tinfoil or gilt paper, nearly of the same size with the electric plate, though it will not be the worse that it is somewhat larger. It is furnished with a glass handle (I), which ought to be screwed into the centre. The manner of using this machine is as follows.—First, the plate B is excited by rubbing its coated side with a piece of new white flannel, or a piece of hare's skin. Even a common hard brush, having the hair a little greased, will excite sulphur extremely well. When this plate is excited as much as possible, it is set upon the table with the electric side uppermost. Secondly, the metal plate is laid upon the excited electric, as represented in the figure. Thirdly, the metal plate is touched with the finger or any other conductor, which, on touching the plate, receives a spark from it. Lastly, the metal plate A, being held by the extremity of its glass handle (I), is separated from the electric plate; and, after it is elevated above that plate, it will be found strongly electrified with an electricity contrary to that of the electric plate; in which case, it will give a very strong spark to any conductor brought near it. By setting the metal upon the electric plate, touching it with the finger, and separating it successively, a great number of sparks may be obtained apparently of the same strength, and that without exciting again the electric plate. If these sparks are repeatedly given to the knob of a coated phial, this will presently become charged.

"As to the continuance of the virtue of this electric plate, (says Mr. Cavallo), when once excited, without repeating the excitation, I think there is not the least foundation for believing it perpetual, as some gentlemen have supposed; it being nothing more than excited electric, it must gradually lose its power by imparting continually some of its electricity to the air, or other substances contiguous to it. Indeed its electricity, although it could never be proved to be perpetual by experiments, lasts a very long time, it having been observed to be pretty strong several days, and even weeks, after excitation. The great duration of the electricity of this plate, I think, depends upon two causes: first, because it does not lose any electricity by the operation of putting the metal plate upon it, &c. and, secondly, because of its flat figure, which exposes it to a less quantity of air, in comparison with a tick of sealing-wax, or the like, which, being cylindrical, exposes its surface to a greater quantity of air, that is continually robbing the excited electric of its virtue.

"The first experiments that I made, relative to this machine, were with a view to discover which substance would answer best for coating the glass plate, in order to produce the greatest effect. I tried several substances either simple or mixed; and at last I observed, that the strongest in power, as well as the easiest, I could construct, were those made with the second sort of sealing-wax, spread upon a thick plate of glass. A plate that I made after this manner, and no more than six inches in diameter, when once excited, could charge a coated phial several times successively, so strongly as to pierce a hole through a card with the discharge. Sometimes the metal plate, when separated from it, was so strongly electrified that it darted strong flashes to the table upon which the electric plate was laid, and even into the air, besides causing the sensation of the spider's web upon the face brought near it, like an electric strongly excited. The power of some of my plates is so strong, that sometimes the electric plate adheres to the metal when this is lifted up, nor will they separate even if the metal plate is touched with the finger or other conductor. It is remarkable, that sometimes they will not act well at first, but they may be rendered very good by scraping with the edge of a knife the shining or glossy surface of the wax. This seems analogous to the well-known property of glass, which is, that new cylinders or globes, made for electrical purposes, are often very bad electric at first; but that they improve by being worked, *i. e.* by having their surface a little worn. Paper also has this property.

"If, after having excited the sealing-wax, I lay the plate with the wax upon the table, and the glass uppermost, *i. e.* contrary to the common method; then, on making the usual experiment of putting the metal plate on it, and taking the spark, &c. I observe it to be attended with the contrary electricity: that is, if I lay the metal plate upon the electric one, and, while in that situation, touch it with an insulated body, that body acquires the positive electricity; and the metallic, removed from the electric plate, appears to be negative; whereas it would become positive, if laid upon the excited wax. This experiment, I find, answers in the same manner if an electric plate is used which has the sealing-wax coating on both sides, or one which has no glass plate.

"If the brass plate, after being separated from, be presented with the edge toward the wax, lightly touching it, and thus be drawn over its surface, I find that the electricity of the metal is absorbed by the sealing-wax, and thus the electric plate loses part of its power; and if this operation is repeated five or six times, the electric plate loses its power entirely, so that a new excitation is necessary in order to revive it.

"If, instead of laying the electric plate upon the table, it is

placed upon an electric stand, so as to be accurately insulated, then the metal plate set on it, acquires so little electricity, that it can only be discovered with an electrometer; which shews, that the electricity of this plate will not be conspicuous on one side of it, if the opposite side is not at liberty either to part with, or acquire more of the electric fluid. In consequence of this experiment, and in order to ascertain how the opposite sides of the electric plate would be affected in different circumstances, I made the following experiments:

"Upon an electric stand E, I placed a circular tin-plate, nearly six inches in diameter, which by a slender wire H communicated with an electrometer of pith-balls G, which was also insulated upon the electric stand F. I then placed the excited electric plate D of six inches and a quarter in diameter, upon the tin-plate, with the wax uppermost; and on removing my hand from it, the electrometer G, which communicated with the tin-plate, *i. e.* with the under side of the electric plate, immediately opened with negative electricity. If, by touching the electrometer, I took that electricity off, the electrometer did not afterwards diverge. But if now, or when the electrometer diverged, I presented my hand open, or any other uninsulated conductor, at the distance of about one or two inches, over the electric plate, without touching it, then the pith-balls diverged; or, if they diverged before, came together, and immediately diverged again with positive electricity:—I removed the hand, and the balls came together;—approached the hand, and they diverged: and so on.

"If, while the pith-balls diverged with negative electricity, I laid the metal plate, holding it by the extremity K of its glass handle, upon the wax, the balls came, for a little time, towards one another, but soon opened again with the same, *i. e.* negative electricity.

"If, whilst the metallic rested upon the electric plate, I touched the former, the electrometer immediately diverged with positive electricity; which if, by touching the electrometer, I took off, the electrometer continued without divergence.—I touched the metal plate again, and the electrometer opened again; and so on for a considerable number of times, until the metal plate had acquired its full charge. On taking now the metal plate up, the electrometer G instantly diverged with strong negative electricity.

"I repeated the above-described experiments, with this only difference in the disposition of the apparatus, *i. e.* I laid the electric plate D with the excited sealing-wax upon the circular tin-plate, and the glass uppermost; and the difference in their result was, that where the electricity had been positive in the former disposition of the apparatus, it now became negative, and *vice versa*; except that, when I first laid the electric plate upon the tin, the electrometer G diverged with negative electricity, as well in this as in the other disposition of the apparatus. I repeated all the above experiments with an electric plate, which, besides the sealing-wax coating on one side, had a strong coat of varnish on the other side, and their result was similar to that of those made with the above-described plate."

This is Mr. Cavallo's account of the electrophorus; but there is one part of it in which he must certainly be mistaken. He tells us, that "instead of laying the electric plate upon the table, it is set upon an electric stand, so as to be accurately insulated, then the metal plate set on it acquires so little electricity, that it can only be discovered by an electrometer." In what manner this gentleman came to mistake a plain fact so egregiously, is not easy to determine; but it is certain, that an electrophorus, instead of having its virtue impaired by being insulated, has it greatly increased, at least the sphere of its activity is greatly enlarged. When lying on the table,

Escapement

Electrophorus

Eracaria Agallocha

If the upper plate is put upon it without being touched with the finger, it will not shew much sign of electricity. But as soon as it is put on the electric stand, both the upper and under side appear strongly negative. A thread will be attracted at the distance of eight or ten inches. If both the upper and under side are touched at the same time, a strong spark will be obtained from both, but always of the same kind of electricity, namely, the negative kind. If the upper plate is now lifted up, a strong spark of positive electricity will be obtained from it; and on putting it down again, two sparks of negative electricity will be produced.

The singularity of this experiment is, that it produces always double the quantity of negative electricity that it doth of the positive kind; which cannot be done by any other method yet known. Another very surprising circumstance is, that when the electrophorus remains in its insulated situation, you need not always touch the upper and under side of the plates at once, in order to procure positive electricity from the upper plate: it is sufficient to touch both sides only once. On lifting up the upper plate, a spark of positive electricity is obtained as already mentioned. On putting it down again, a spark of the negative kind is obtained from the upper plate, even though you do not touch the lower one. On lifting up the upper plate, a spark of positive electricity is obtained, but weaker than it would have been had both sides been touched at once. Putting down the upper plate again without touching both, a still weaker spark first of negative and then of positive electricity will be obtained from the upper one. Thus, the sparks will go on continually diminishing, to the number perhaps of two or three hundred. But at last, when the electricity of the whole machine seems to be totally lost, if both sides are touched at once, it will instantly be restored to its full strength, and the double spark of negative, with the single one of positive electricity, will be obtained without intermission as before.

To account for all these phenomena very particularly, is perhaps impossible, without a greater degree of knowledge concerning the internal fabric of bodies than we have access to attain. In general, however, it is evident, that the phenomena of the electrophorus arise from the disposition that the electric matter hath to keep up an equilibrium within itself throughout every part of the universe. In consequence of this, no motion of the electric matter can be produced upon the one side of a body, but it must immediately be balanced by a corresponding one on the opposite side; and in proportion to the strength of the one, so will the strength of the other be. When the under plate of the electrophorus is excited, the negative electricity, or vibratory action of the electric matter towards the excited side, is produced; and the moment that such an action is produced on one side, it is resisted by a similar one on the opposite side, and thus the electrophorus becomes negatively electrified on both sides. As long as the under part of the machine communicates with the earth, the vibratory motion is impeded by the progressive one towards the earth. This makes the resistance on the under side less, and therefore the vibratory motion on the upper part extends but a small way. When the plate is insulated, the electric matter has not an opportunity of escaping to the earth as before, because it is strongly resisted by the air; a vibration therefore takes place on both sides, and extends to a great distance from the plate. When the upper plate is set upon the electrophorus, the same kind of electricity, viz. the negative kind, is communicated to it. When both sides are touched, with the finger, or with any other conducting substance, both electricities are suddenly taken off, because the electric matter running along the conducting substance on both sides, puts an end to the vibratory motion in the air, which constitutes the

very essence of what we call electricity. There is now a quiet and equal balance of the electric matter on both sides, and therefore no signs of electricity are shewn. But as soon as the upper plate is taken off, this balance is destroyed. The fluid in the metal plate had not been able to penetrate the electric substance in such a manner as to put a stop to the vibrations of what was within it. As soon then as the plate is taken off, the electricity, or vibratory motion towards the electric, breaks out at that side. But this motion inwards to the electric, which constitutes negative electricity, necessarily becomes outward from the plate; and as no motion of the fluid can be produced on one side of a body, but what is immediately communicated to the other, the upper plate becomes electrified positively, and the under one negatively on both sides.

ELEVATOR, a mechanical contrivance for raising any thing to an height from the surface of the earth.—The following description of a machine called a *speedy elevator*, invented by Dr. Collin, appears in the Transactions of the American Philosophical Society, and the doctor was honoured with the Magdallian gold medal for this invention.

The main body of the base is a rectangular solid floor. (See F. W. Plate 27). To its corners are jointed four horizontal legs, of equal thickness with it, but half the length, having their nether sides even with its bottom. When the machine is used, these are displayed so that their ends form a rectangle; the diagonals of which may be on those of the main body, or vary from them in a position most promotive of stability.

The pillars A A stand vertical on the long diameter of the base, equally distant from its ends. Their feet enter into it, and are by strong fastenings incorporated with its body. These pillars are pairs. Their form is a rectangular parallelepiped. Their inner sides have grooves from top to bottom, which terminate by offsets in cylindric segments. Near the tops are central embrasures, whose sides are fortified with iron plates that reach within the solid parts above and below. The pulleys are of metal, with steel axes and brass naves for easy turning, and deep channels for securing the cords.

The pillars are joined by three pairs of ribs. These are rectangular; and wide, but comparatively thin; placed horizontally, between the tops and embrasures, above the middles, and near the feet. Their ends are closely fitted within the pillars, and well fastened.

The piers B B are more slender than A A; with shorter heads; but the length of their bodies is equal to the whole of these. They have similar grooves, embrasures, pulleys, and joining ribs. Their faces are parallel rectangles. The backs of their bodies have tongues along the middles that fit the grooves of A A. These are vertical rectangular ridges, and parts of the very pieces, formed by cutting down both sides to a proper level. These lower surfaces, being even and smooth, will thus move close along the corresponding plain parts of A A while the tongues glide in contact with the sides of the grooves.

The cords a a are well paired in length and texture; They ply over the pulleys of A A in the said hollows behind the grooves; having their ends fixed under the feet of B B, and on the boxes of the windlafs. This is well secured in the base, close to and right beneath the pillars.

The cords b b are fastened by one end on the heads of A A. They pass over the pulleys of B B, and reach as far below them as a a reach below the pulleys of A A, which is the distance of these pulleys from the base. Their other ends are tacked a little above the bottoms of the piers C C.

These piers are with their apparatus framed like B B; have less bulk and shorter heads. Their pulleys clear the tops of B B when the machine is down.

The cords c c have the same length with b b, below the

pulleys of CC; plying over these; fastened on the heads of BB, and somewhat above the bottom of the pier D.

This is a single piece. It has two backs to fit the grooves of CC, formed like the backs of the other pieces.

A frame is accurately fixed and poised on the top of D. In this the load L is placed, so that its centre of gravity is exactly or very nearly over the centre of the frame.

When the power begins to wind the cords *aa*, these raise the piers BB. As they rise, their pulleys recede from the tops of AA, and by stretching the cords *bb* lift the piers CC. These recede at the same time from the tops of BB, and lift the pier D. Thus while BB are wound up from the base to the height of the pulleys of AA, D rises treble that height; and, however great may be the number of moving pieces, it multiplies the celerity and acquired elevation of the uppermost by that of the first.

As the duration and celerity of all the movements is the same, the lengths of all the cords below the respective pulleys must be equal.

As the whole acquired elevation is by those parts of the piers which are drawn out of their folds, these ought to have a very great proportion. Therefore BB reach the base when down; and the heads of AA are but long enough to keep them safe in their grooves, when drawn up. Again, as the ends of the cords *bb* will be above the base according to the length of the heads of AA, the heads of BB are shortened, and the bodies of CC are prolonged below those ends, in order to save room, and yet afford these piers a secure depth in the grooves of BB, when drawn up. On the same principle the heads of CC are shortened, and a part of D left under the ends of *cc*. As these additions of said pairs cannot increase the elevation, the cords ought to be fixed above them in order to shorten the bearings, and so far make the bodies firmer. In a longer series of piers this shortening of the heads can only be continued to the limit of depth necessary to support the frames.

The pier D prels the cords *c c* by its own weight, and the load L. This pressure causes an equal pulling and consequential resistance in the tops of the piers BB. The pulleys of the piers CC must bear this double pressure $= 2L + 2D$. These therefore press the cords *bb* with said weight and their own $= 2L + 2D + CC$. This doubled $= 4L + 4D + 2CC$ is the pressure on the pulleys of BB; but their heads are pulled up by $L + D$: the difference of these forces added to their own weight is the pressure of these piers on the cords *aa*, $= 3L + 3D + 2CC + BB$. The power on the windlafs must be equal to this.

In any series the power must lift a weight equal to the first piers, double the second, and so forth, till the last pier and its load multiplied by the number of moving pieces.

The pulleys, cords, and ribs, have some weight, and are to be counted as parts of their respective piers. A competent allowance is likewise required for the friction of the pulleys, which impedes the ascent, though the descent is advantageously retarded by it.

The pressure on the pulleys of the pillars AA is double the power. The strain in their tops is half of the weight on the pulleys of BB. The difference of these forces, $= 4L + 4D + 3CC + 2BB$, added to their own weight, is the pressure on the base.

The strain in the tops of any piers in a series is equal to what the power would be, if the pair next above was the last. The weight on the pulleys of the same pair is double the strain in the tops of the pair next below. The strain on their feet is equal to the strain in the tops of the pier two ranks below.

It is very necessary to compute the strains and pressures in

order to secure all the parts, and to save needless bulk, which would be a great disadvantage in the piers by the additional expence of power. The pressure of vertical pieces by their own weight must be counted, though not as equal to the same quantity of external burthen laid upon them: its operation is visible in high massive beams, which bend without any load; but in short though slender pieces it is not sufficient to break the internal cohesion of the parts. The effect of external weight is according to its quantity, and to the height and firmness of the piers; but not in uniform proportions. Divers kinds of wood have also different degrees of weight, and of vertical firmness: some are both stiff and light to an admirable degree: piers made of these can under slender forms bear weights many times greater than their own. These qualities are in their blended effects of different value in this machinery: the pillars are the most pressed, but they cause no weight to the power, and therefore their bulk is the less detriment. BB being the heaviest laden piers are the most solid, but they have only a simple moment: CC bearing less are lighter, but their moment is double: D has a treble moment, but the lightest burthen, and thus the least weight of its own. These continually growing increments of solidity are necessary consequences of the constant double bearings; but ought to be small in comparison to the pressures thus produced, which become very great, when the load to be lifted and the elevation are considerable. Lightness is then most beneficial in the upper ranks, and firmness in the lower, at these must lift but these be lifted many times: accordingly different sorts of wood may be chosen by their degrees of lightness and firmness; they being otherwise proper, especially for close and smooth folding.

On account of the grooves and tongues, the pieces cannot have those regular forms that give the greatest solidity; nor can the pulleys be placed exactly over the line of central strength. In practice, these defects must not exceed necessary limits. Moreover, when the pressures and strains on the several parts of the pieces are estimated, hollows may be contrived in places that can bear it.—These niceties cannot be marked in a model.

When the load, the elevation, and quality of the wood, are given; the lightest series of piers is found by computing the results from different numbers. A greater number must effect a greater proportion of the whole elevation than a smaller, because the pillars, by becoming shorter, contribute less; this addition is a new expence of power. The weight of the load is essential, as it must be multiplied by the whole number of piers; it imparts the same moment to its own pier of competent bulk; and in conjunction with it thickens with continual increase all the others. On the other hand the firmness of piers affects greatly with the decrease of their height within certain limits. Some species of wood have also corresponding degrees of strength. The co-operation of these advantages may therefore render a considerable number of short piers light, and proportionally so in their respective multiple moments. The more numerous the piers are, the sooner is the machine wound up, and let down, which is an advantage, so far as men can make greater exertions for a short time.

The form of the windlafs determines, in combination with the preceding, the speed of operation, and the degree of power. It admits various modes: for example, one might be placed on either side of the pillars, with long handles on the winches; by which eight men can work together. This model is intended to shew considerable effects from an easy apparatus: accordingly two men lift another, and three tiers of piers: they are aided by a sufficient projection of the winches beyond the semidiameter of the boxes: this has such proportion to the height of the pulleys in the pillars, and the equal

Fire Escape

Elevator

length of the cords *aa* below them, that the whole winding is done by a few turns. The dimensions of the piers are not effected, as my experiments are not sufficient; but I estimate them so, that the elevation is at least fifty feet. The power increases, though the velocity decreases, by lessening the width of the boxes; and this can be done while their length can so correspond, that the rounds of the cords *aa* have sufficient room, when the machine is wound up.

Oblique pressures cannot arise from the principles of construction; but happen from inevitable imperfection of materials and workmanship in a small degree, which is not an object of exact calculation, but should have full allowance for its effects on the machine. The obliquity will be the greater as the folding is shallow, and the fitting is loose. The effect results jointly from the angle of declination, the length of the pier, and its moment of weight. The oblique bearings on the ends of the tongues, when the machine is wound up, will be dangerous, if these have not a competent solidity. All the piers with their moments of weight bear on the pillars; and the pressure on their pulleys is the difference between double the power and the strain of their heads, which balance is very great. This pressure remains there when the machine is wound up, in every stage of the elevation, however great. The common centre of gravity of the pulleys thus pressed, the pillars themselves, and the base, is below the pulleys. Thus the machine has a great stability, and the base is accordingly not extensive.

This machine combines these advantages: ready approach to heights otherwise not accessible without great trouble: speedy ascent and descent: convenient folding for keeping under cover, and for easy conveyance. It can be applied to several useful purposes:—Quick hoisting and lowering of things on many occasions; particularly saving of goods from upper stories in cases of conflagration: high elevation and speedy descent of signals: these being light may be raised three hundred feet, and above interjaect hills: elevation of a person for taking views; and quick descent when required; as on reconnoitring an enemy within shot: a machine calculated for lifting him at least one hundred feet by eight men can be light enough for carrying on a waggon by two horses.

ELEUTHES, a kingdom of Tartary, lying to the N.W. of Chinese Tartary. It was conquered, in 1759, by the Emperor of China. See KALMUCKS.

ELIAS, the prophet, memorable for having escaped the common catastrophe of mankind; being taken up alive into heaven, in a fiery chariot, about 895 B. C. See the Bible.

ELICHMAN (John), a native of Silesia in the 17th century, who practised physic at Leyden, and was remarkable for understanding 16 languages. He supported an opinion, that the German and Persian languages were derived from the same origin. His Latin translation of the *Tablet of Cebes*, with the Arabic version and the Greek, was printed at Leyden in 1640, under the care of Salmassius, who prefixed thereto a very ample preface.

ELISHA, the prophet, famous for the miracles he performed, died about 830 B. C. See the Bible.

ELIZABETH, queen of England, daughter of Henry VIII. and Anna Boleyn, was born at Greenwich, September 7th, 1533. According to the humour of the times, she was early instructed in the learned languages, first by Grindal, who died when she was about 17, and afterwards by the celebrated Roger Ascham. She acquired likewise considerable knowledge of the Italian, Spanish, and French languages. Dr. Grindal was also her preceptor in divinity, which she is said to have studied with uncommon application and industry. That Elizabeth became a protestant, and her sister Mary a papist, was the effect of that cause which determines the religion of all mankind; namely,

the opinion of those by whom they were educated: and this difference of opinion in their tutors, is not at all surprising, when we recollect, that their father Harry was of both religions, or of neither.

But the studies of our illustrious princess were not confined merely to languages and theology: she was also instructed in the political history of the ancients; and was so well skilled in music, as to sing and play "artfully and sweetly."

After the short reign of her brother Edward, our heroine being then about 20 years of age, her sister *firebrand* according to the crown, Elizabeth experienced a considerable degree of perfection, so as to be not a little apprehensive of a violent death. She was accused of nobody knows what; imprisoned; and, we are told, inhumanly treated. At last, by the intercession of King Philip of Spain, she was set at liberty; which she continued to enjoy, till, on the death of her pious sister, she, on the 17th of November, 1558, ascended the throne of England. Her political history, as a queen, is universally known and admired: but her attention to the government of her kingdom did not totally suspend her pursuit of learning. Ascham, in his *School-master*, tells us, that, about the year 1563, five years after her accession, she being then at Windsor, besides her perfect readiness in Latin, Italian, French, and Spanish, she read more Greek in one day, than some prebendaries of that church did read Latin in a whole week (p. 21).—She employed Sir John Fortescue to read to her, Thucydides, Xenophon, Polybius, Euripides, Æschines, and Sophocles. (*Ballard*, p. 219.)—That the Latin language was familiar to her, is evident from her speech to the university of Oxford, when she was near sixty; also from her spirited answer to the Polish ambassador in the year 1598.—And that she was also skilled in the art of poetry appears, not only from the several scraps which have been preserved, but likewise from the testimony of a cotemporary writer, Puteham, in his *Art of Engl. Poetry* (a very scarce book). These are his words:—"But, last in recital, and first in degree, is the queen, whose learned, delicate, noble muse, easily surmounteth all the rest, for sense, sweetness, or subtilty, be it in ode, elegy, epigram, or any other kind of poem," &c. In this author are to be found only a specimen of 16 verses of her English poetry. "But," says Mr. Walpole, "a greater instance of her genius, and that too in Latin, was her extempore reply to an insolent prohibition delivered to her from Philip II. by his ambassador, in this tetraic:

Te veto ne pergas bello defendere Belgas:
Quæ Dracus eripuit, nunc restituantur oportet:
Quas pater everit, jubeo te condere cælas:
Religio papæ fac restituantur ad unguem.

"She instantly answered him, with as much spirit as she used to return his invasions,

Ad Græcos, bone rex, sient mandata calendæ."

Being earnestly pressed by a Romish priest, during his peripetia, to declare her opinion concerning the real presence of Christ's body in the wafer, she answered,

Christ was the word that spake it;
He took the bread, and brake it;
And what that word did make it,
That I believe, and take it.

Fuller's Holy State.

She gave the characters of four knights of Nottinghamshire in the following distich:

Gervase the gentle, Stanhope the stout,
Markham the lion, and Sutton the lout.

Walp. Cat.

Coming into a grammar-school, the characterised three classic authors in this hexameter :

Perfius a crab-staff; bawdy Martial; Ovid a fine wag;
Full, Worth. of Warw. 126.

Sir Walter Raleigh having wrote on a window,

Fain would I climb, yet fear I to fall;

She immediately wrote under it,

If thy heart fail thee, climb not at all.

Worth. of Devonsh. 261.

Doubleless, she was a woman of singular capacity, and extraordinary acquirements; and, if we could forget the story of the Scottish Mary, and of her favourite Essex, together with the burning a few Anabaptists, we might pronounce her the most illustrious of illustrious women. She died in her palace at Richmond, the 24th of March, 1602, aged 70, having reigned 44 years; and was interred in the chapel of Henry VII. in Westminster Abbey. Her successor James erected a magnificent monument to her memory.—She wrote, 1. *The mirror, or glass of the sinful soul*. This was translated out of French verse into English prose, when she was eleven years old. It was dedicated to Queen Catharine Parr. Probably it was never printed; but the dedication and preface are preserved in the *Sylloge epistolarum*, in Hearne's edition of *Livii Fori Julenſis*, p. 161. 2. *Prayers and meditations*, &c. Dedicated to her father, dated at Hatfield, 1545. Manuscript, in the royal library. 3. *A dialogue out of Xenophon, in Greek, between Hiero a king, yet some time a private person, and Simonides a poet, as touching the life of the prince and private man*. First printed, from a manuscript in her Majesty's own handwriting, in the Gentleman's Magazine for 1743. 4. Two orations of Isocrates, translated into Latin. 5. Latin oration at Cambridge. Preserved in the king's library; also in Holinshed's Chron. p. 1206; and in Fuller's Hist. of Cambr. p. 138. 6. Latin oration at Oxford. See Wood's Hist. and Antiq. of Oxf. lib. 1. p. 289, also in Dr. Jebb's Append. to his life of Mary queen of Scots. 7. A comment on Plato. 8. *Boethius de consolatione philosophiæ*, translated into English anno 1593. 9. *Salustii de bello Jugurthino*, translated into English anno 1590. 10. A play of Euripides translated into Latin, *Cut. of Royal Auth.* 11. A prayer for the use of her fleet in the great expedition in 1590. 12. Part of Horace's art of poetry, translated into English, anno 1598. 13. *Plutarch de curiositate*, translated into English. 14. Letters on various occasions to different persons; several speeches to her parliament; and a number of other pieces.

ELIZABETH PETROWNA (daughter of Peter the Great), empress of Russia, distinguished herself by her signal clemency. She made a vow, that no person should be put to death in her reign, and she strictly observed it. The example was followed, and confirmed by law, under the late Sovereign of Russia, Catharine II. Elizabeth died in 1762, in the 21st year of her reign and 52d of her age.

ELIZABETH ISLAND, an island on the coast of Massachusetts Bay, having Cape Cod to the N. and the island of Nantucket to the E. The natives are chiefly employed in the fisheries. Long. 69. 3. W. Lat. 42. 0. N.

ELIZABETH TOWN, one of the oldest towns of the state of New Jersey; purchased of the Indians in 1664, and settled soon after. It has a handsome Presbyterian church, an episcopal church, and an academy. It is 15 miles S.W. of New York.

ELKHOLM, a sea-port of Sweden, in Blekingen, seated on the Baltic, 24 miles W. of Carlscroon. Long. 14. 50. E. Lat. 56. 20. N.

ELLERENA, an episcopal town of Spain, in Estremadura, 54 miles N. of Seville. Long. 5. 20. W. Lat. 38. 26. N.

ELLESMERE, a town in Shropshire, with a market on Tuesday. It is seated on a large mere, in a small but fertile district of the same name, 16 miles N.N.W. of Shrewsbury, and 176 N.W. of London. Long. 2. 53. W. Lat. 53. 53. N.

ELlichPOUR, a town of Hindoostan, in Berar, capital of a Circar of the same name, subject to the nizâm of the Deccan. It was formerly the capital of Berar, and is 744 miles N.E. of Aurangabad. Long. 78. 5. E. Lat. 21. 12. N.

ELLORE, the capital of one of the Northern Circars, in the peninsula of Hindoostan, 32 miles N. of Malaputnam. Long. 81. 15. E. Lat. 16. 43. N.

ELM (*Adia.*). Cit. Boucher, in a memoir read before *la Société d'Emulation at Abbeville*, has given some observations on elm-trees. These trees are frequently attacked by ulcers, from which, at length, a great number of them perish. *Du Hamel* had already endeavoured to find out the cause of this disease, and ascribed it to a plethora of the sap, an opinion which Cit. Boucher has confirmed by numerous experiments. He proposed at the same time a remedy, which he successfully applied to it. He observed that the local ulcer never attacked the trees on their north side, but always on the south side; it acts principally on trees planted in a boggy soil, and along the sides of rivers. Its seat is generally not far from the ground. This ulcer, owing to a superabundant sap, differs from a similar one, described in *Journal d'Agriculture Naturelle*, No. 5, 1789, as in this the liquor exuded to the air; soon takes the consistency of a gum, and has the flavour of sugar.—The remedy consists in boring every tree attacked by the disease, at the ulcer itself; and in applying a tube in the hole, occasioned by the borer, penetrating about nine lines in depth. The sound trees, which are also bored, afford no liquor, whereas those that are ulcerated yield it in great abundance, increasing particularly in fine weather, and when the wound is exposed to the south. Stormy weather and great winds stop the infusion. In this manner, he remarks that the ulcers dry and heal in 48 hours. It is probable, that such a trephination, tried on other vegetables, and particularly on fruit trees, will produce the same effects. Pliny, Columella, and Palladius, have already mentioned this expedient being employed by the ancients, which, however, has not been practised for many years. Cit. Boucher concludes by remarking, that this tree is a native of Europe, and has not been lately introduced into France, as is commonly supposed; but the writings of the ancients prove, that it existed there long ago.—The chemical analysis which he made of the sap, shewed that it contained a considerable quantity of acetite of potash, a little acetite of lime, a certain quantity of vegetable or mucro-faccharine matter, and a considerable proportion of muriate of lime; slight traces of sulphate and muriate of potash were likewise perceived.

ELMADIA, or MAHADIA, a town of the kingdom of Tunis, seated on the gulf of Capes. It is surrounded by the sea, is well fortified, and has a good harbour. It was taken by Emperor Charles V. but retaken soon after. Long. 8. 47. W. Lat. 35. 4. N.

ELME, St. a castle of the isle of Malta, seated on a rock near the city of Waletta, at the mouth of a very fine harbour.

ELMO, FORT, St. a fortress of France, in the department of the Eastern Pyrenees, seated on the river Tet, five miles N. of Collioure. It was taken by the Spaniards, in 1793, but retaken the next year.

ELPHIN, a town of Ireland in the county of Roscommon, and (the see of a bishop), eight miles N. of Boyle, and 16 N. of Roscommon.

ELRICH, a town of Upper Saxony, formerly the capital of the county of Klettenburg. Here are some considerable manufactures. It is 6 miles N.W. of Nordhausen.

ELSFLETH, a town of Westphalia, seated at the conflux of the Hunte and Weser, 17 miles N.E. of Oldenburg.

ELTEMAN, a town of Franconia in the bishopric of Wurtzburg, on the river Maine. Long. 10. 52. E. Lat. 50. 8. N.

ELTENBERG, a lofty and extensive mountain in the duchy of Cleves. On it is an ancient fortress. It stands at the extreme point of a promontory, six miles E. of Cleves; and is the termination of a large chain of hills that runs parallel to the E. shore of the Rhine, at the distance of ten miles from its borders.

ELTHAM, a town in Kent, with a market on Monday, eight miles S. of London. Here are the remains of a palace, in which Edward II. often resided, and his son, John of Eltham, was born. Its stately hall, till entire, is converted into a barn.

ELTZ, a town of Germany, in the bishopric of Hildesheim, seated on the Leina, ten miles S.W. of Hildesheim. Long. 10. 5. E. Lat. 52. 5. N.

ELWANGEN, a town of Suabia, with a chapter, whose provost is a prince of the Empire, and lord of the town. It is seated on the Jaxt, 17 miles S.E. of Halle, and 25 S.W. of Anspach. Long. 10. 28. E. Lat. 49. 2. N.

EMBALMING, (*Enceyl.*). On the subject of embalming, the following directions are given in the **EDINBURGH PRACTICE OF PHYSIC AND SURGERY**, &c. lately published.

"After evisceration, as has been directed in opening a dead body, and continuing the incision further upwards, even into the mouth, and, if possible, without cutting the skin of the neck, all the cavities are to be well cleansed, and the humidity sucked up with sponges, then washed with *tinct. myrrhe*, and filled with spices compounded of fragrant herbs, aromatic drugs, and gums reduced to powder not very fine, first restoring the heart to its former residence, after having opened its ventricles, cleansed and washed them with the tincture, stuffed them with the spices, and sewed them up; and then the cavities are to be stitched very close with the gloves' or spiral future. Large and deep incisions are also to be made in all the most fleshy parts, cleaning and washing them with the tincture in the same manner, filling them with the antiseptic spices, and stitching them up. Then the head, trunk, and limbs, are to be perfectly well covered with cereloth; putting a piece under the chin, to be secured by sewing on the top of the head, after having well adjusted the cap of the skull, sewed the scalp together, and cleaned the mouth, as has been directed for the other parts, and putting in some of the spices. The cereloth is to be prepared, according to art, with a composition made of wax, rosin, storax, and painters' drying oil. After the application of the cereloth, with great care and exactness, cut into suitable pieces according to the respective parts, and closing them well every-where, the face being close shaved, is to be covered with some of the above composition melted, and laid on with a brush of a proper degree of heat, and of a moderate thickness; which may have a faint flesh-colour given it with vermilion; and when it is grown cold and stiff upon this part, it may be lightly covered with hard varnish; or this varnish, applied thick, may here serve the purpose alone. A cap is to be well adapted to the head, falling down upon the neck, and to be sewed under the chin, making a few circular turns about the neck with a roller of a proper breadth. All the rest of the corpse is to be inclosed in a sheet, to be artfully cut, and sewed on very close and smooth, with the finest tape, and the *flat seam* mentioned in the preceding chapter; over which an appropriate dress is to

be put, as the relations or friends think fit to direct and appoint, and then laid into the coffin, which should be in readiness: but when it is some great personage, who is to lie in state for public view before the funeral rites are solemnized, the dress must be appropriated to his dignity and character. The brain and other viscera are to be put with some of the spices into a leaden box. Sometimes the heart, prepared as has been directed, to preserve it from putrefaction, is deposited in an urn by itself.

EMANATION, the act of flowing or proceeding from some source or origin; or the thing that proceeds from that action.

EMBANKMENT, a raised mound or body of earth, thrown up to preserve land from inundation, and thus render it fit for agricultural purposes. This is a very important branch of rural economy, and has been much encouraged in this country.

The following account of an embankment against the sea, by Mr. Anthony Tatlow, is taken from the communications to the Hon. Board of Agriculture.

"The embankment against the sea," says Mr. Tatlow, "that I mentioned when last at the Museum, is upon the estate of the earl of Ashburnham, at Pembrey, in the county of Carmarthen, whither his lordship sent me upon his coal and other business, and with directions to see if I could devise any method of preventing the sea from making further incroachment upon his property, which it had been doing for many years; and particularly in October 1795, had broke in and covered many hundred acres, damaged the houses, buildings, stack-yards, and gardens; and it was the general opinion, that a regular embankment must be formed, which would cost some thousand pounds, he having several miles of coast. The view that I first took was upon a very windy day, and the shore an entire sand, which extended at low water many miles. In riding along, I perceived that any piece of wood, or accidental impediment to the course of the land, raised a hill: it immediately occurred to me, that by making a hedge at the weak and low places, with wings to catch the sand as the wind blew it in different directions, I should obtain the desired effect. I therefore directed stakes nine feet long to be cut, and driven one foot and a half into the sand, at two feet and a half distance from each other; betwixt which I had furze interwove, so as to form a regular furze hedge seven feet and a half high. Of this, since last June, I have done eleven hundred and thirty-seven yards; and in October last when I was there, a great deal of the hedge was covered, and since that time I am informed by letter, that a great deal more of it is so; and that the neighbouring inhabitants draw great comfort to themselves, from the security my furze embankment gives them, as its present appearance plainly evinces, that at a trifling expence I can secure Lord Ashburnham's estate from being inundated; for, whenever the first hedge is not high enough to prevent the sea overflowing, another may be built upon the sand formed by that hedge, and so on in succession, till it is perfectly safe."

EMBO, a village near Brora, on the E. coast of Sutherlandshire. Here a person was burnt, in 1727, for the imaginary crime of witchcraft; the last instance of these fanatic executions in Scotland.

EMBOLY, a town of Macedonia, with a Greek archbishop's see. It is the ancient Amphipolis; and is sometimes called Christopolis. It is seated on the Stromona, 40 miles N.E. of Salonichi. Long. 23. 55. E. Lat. 40. 59. N.

EMBS, a river of Westphalia, which rises in the county of Lippe, and falls, at Embden, into the Dollart, a bay of the German Ocean.

EMBS, or **EMS**, a town of Suabia, capital of a county of the same name. Near it are some baths impregnated with sulphur. It is 10 miles S. of Bregentz.

EMERALD (*Encycl.*). Cit. Vauquelin has lately discovered *chrome and a new earth in the emerald*, and asserts that he formerly found these substances in the beryl. He also states the analysis of the pulverulent chlorite, which contains 26 parts of silex, 18.5 of alumine, 8 of magnesia, 43 of oxyd of iron, 2 of muriate of soda, or potash, and 2 of water; a result which is different from all that have hitherto been given in the analysis of chlorites. He attributes this difference, rather to the nature of this apparently mixed earth than to the inaccuracy of chemical operations.

EMESSA, a town of Syria, in the government of Damascus. There are still noble ruins, that shew it was anciently a magnificent city.

EMPOLI, a town of Tuscany, with a bishop's see, seated on the Arno, 17 miles S.W. of Florence. Long. 11. 6. E. Lat. 43. 42. N.

ENCKHUYSEN, a sea-port of N. Holland, on the Zuider-Zee. It was once a flourishing place; but its harbour being now obstructed by sand, it has lost its former consequence. It is 25 miles N.E. of Amsterdam. Long. 5. 4. E. Lat. 52. 45. N.

ENDEAVOUR STRAIT, a strait of the S. Pacific Ocean, which separates New Guinea from New Holland. It received its name from Captain Cook, who explored it in 1770. Its length is 10 leagues, and its breadth about five, except at the N. E. entrance, where it is contracted to less than two miles, by the islands called Prince of Wales' Islands.

ENDINGEN, a town of Suabia, in Austrian Brigauf, formerly free and imperial. It is seated near the Rhine, 10 miles below Brisaach.

ENFIELD, a town in Middlesex, with a market on Saturday. It was once famous for an extensive royal chase, disforested in 1779. Here was a royal palace, whence Edward VI. went in procession to the Tower, on his accession to the throne. After the death of Queen Elizabeth, it was alienated from the crown; and only a small part of it is left standing, the whole of the front having been taken down, in 1792, and its site occupied by some houses. It is 10 miles N. of London. Long. 0. 2. E. Lat. 51. 41. N.

ENGADINA, a country of the Grisons, in the mountains of the Alps. It is divided into Upper and Lower, extending along the banks of the river Inn, from its source to the Tyrolite. Upper Engadina is a beautiful valley; yet, on account of its elevation, produces nothing but rye and barley. The winter sets in early, and ends late here, during which time sledges are the common vehicles. Even in summer, the air is cold and piercing, and the corn occasionally much damaged by the hoar frost.

ENGELBERG, a valley of Switzerland, 10 miles long, entirely surrounded by very lofty and barren mountains, and bounded by the cantons of Bern, Uri, and Unterwalden. It is subject to the abbot of a Benedictine monastery of the same name, who is under the protection of the cantons of Lucern, Uri, Schwitz, and Unterwalden; but in spiritual concerns he submits to the jurisdiction of the Bishop of Constance. His revenues are very considerable, and arise principally from his commerce in cheeses. The naturalist will find this a very interesting country. Glaciers, of a very great extent, and extremely diversified, are found on the sides of very fertile mountains, and exhibit singular points of view. There is abundance of fine black marble, white veined; a vitriolic earth, slate impregnated with vitriol; small crystals, called Swiss diamonds; silver, and vitriol. The abbey is 12 miles S.W. of Altdorf. See **TITLISBERG**.

ENGERS, a town of Germany in the electorate of Treves, capital of a county of the same name. It is seated on the Rhine, 10 miles N. of Coblenz. Long. 7. 32. E. Lat. 50. 35. N.

ENGHEIN, a town of Austrian Hainault, near which was fought the famous battle of Steenkirk. It is 15 miles S.W. of Brussels. Long. 4. 5. E. Lat. 50. 42. N.

ENGIA, or **ENGINA**, an island of Turkey in Europe, in a gulf of the same name, between Livadia and the Morea. There is a town upon it of the same name, 22 miles S. of Athens. Long. 23. 59. E. Lat. 37. 45. N.

ENGROSSING, the writing a deed over fair, and in proper legible characters. Among lawyers it more particularly means the copying fair upon parchment, or stamped paper, any writing or legal instrument or conveyance. Engrossing is the business of the law-stationer.

ENKIOPING, a town of Sweden, in Uppland, on the N. side of Lake Maelar, 21 miles S.W. of Upsal.

ENNIS, a borough of Ireland, in the county of Clare. It is large and populous, and situate on the Fergus, which is navigable for large boats from the Shannon, and adds greatly to the trade of the town. It is 17 miles N.W. of Limerick. Long. 8. 54. W. Lat. 52. 49. N.

ENNISCORTHY, a borough of Ireland, in the county of Wexford, where is a manufacture of coarse woollen cloth, and some considerable iron works. It is situate on the Slaney, close under Vinegar-hill, where the Irish rebels were entirely defeated on June 21, 1798. It is 10 miles N. of Wexford, and 27 N.E. of Waterford.

ENO, or **ENOS**, a town of Romania, near the gulf of Enos, with a Greek archbishop's see, 125 miles W. of Constantinople. Long. 26. 15. E. Lat. 40. 46. N.

ENOCH (the Prophecy of); an apocryphal book, of which there remains but a few fragments.

Enoch was certainly one of the most illustrious prophets of the first world, since Moses says of him, that *he walked with God*. This prophet is famed in, the church for two things: The first is, his being taken up into heaven, without seeing death (Heb. xi. 5.); the second is, his prophecy; a passage of which St. Jude has cited in his epistle, ver. 14. The ancients greatly esteemed the prophecy of Enoch. Tertullian, on the authority of this book, deduces the original of idolatry, astrology, and unlawful arts, from the revolted angels, who married with the daughters of men. And it is on the testimony of this book, that the fathers of the 2d and 3d centuries, as Irenaeus, Cyprian, and Lactantius, received for true this fable of the marriage of the angels with the daughters of men. St. Augustin, who was less credulous, allows, indeed, that Enoch wrote something divine, because he is cited by St. Jude; but insinuates, that the authority of this book is doubtful, and that it cannot be proved that it was really written by Enoch. Indeed, the account it gives of giants engendered by angels, and not by men, has manifestly the air of a fable; and the most judicious critics believe, it ought not to be ascribed to Enoch.

ENSENE, a town of Egypt, on the E. side of the Nile, 120 miles S. of Cairo. Long. 30. 54. E. Lat. 28. 5. N.

ENSKIRKEN, a town of Germany, in the duchy of Juliers, 15 miles S.W. of Cologne. Long. 6. 19. E. Lat. 51. 0. N.

ENSTORF, a town of the upper palatinate of Bavaria, 22 miles N. of Ratibon.

ENT (Sir George), an eminent English physician, born at Sandwich in Kent in 1604. He was educated at Sidney College, Cambridge; and, afterwards travelling into foreign countries, received the degree of doctor of physic at Padua. After his return he obtained great practice, was made president of the College of Physicians in London, and at length received the honour of knighthood from King Charles II. He was extremely intimate with Doctor Harvey; whom he learnedly defended in a piece entitled, *Apologia pro Circulatione Sanguinis, contra Æmilium Panisæum, Animadversiones in Malacchie*

Thrustoni; and some observations in the Philosophical Transactions. Glanville, speaking of his Plus Ultra of the modern improvements in anatomy, numbers Sir George Ent, Doctor Glisson, and Doctor Wallis, with the most celebrated discoverers in that science. The two former were among the first members of the Royal Society. Sir George Ent died in October 1689.

ENTRE-DOUERO-E-MINHO, a province of Portugal, 45 miles in length, and 35 in breadth. Braga is the capital.

ENTRY of an *Heir*, in Scots law, that form of law by which an heir vests in himself a proper title to his predecessor's estate.

EPERIES, a town of Upper Hungary, capital of the county of Saros, remarkable for its mines of salt. It is seated on the Tuzsa, 20 miles N. of Cassovia. Long. 21. 13. E. Lat. 49. 8. N.

EPERNAY, an ancient town of France, in the department of Marne. It was taken by Henry IV. in 1592, when Marshal Biron was killed, while that monarch had his hand on his shoulder. The wines produced in its neighbourhood are very exquisite. It is 17 miles N.W. of Chalons. Long. 4. o. E. Lat. 49. 6. N.

EPINAL, a town of France, in the department of the Vosges, and famous for its paper mills. It was taken by Marshal Cressy, in 1670, when its fortifications were dismantled. It is seated on the Moselle, near the mountains of the Vosges, 35 miles S.E. of Nancy. Long. 6. o. E. Lat. 48. 4. N.

EPIPHANIUS (St.), an ancient father of the church, born at Befanducan, a village in Palestine, about the year 332. He founded a monastery near the place of his birth, and presided over it. He was afterwards elected bishop of Salamis; when he sided with Paulinus against Meletius, and ordained in Palestine, Paulinian, the brother of St. Jerom; on which a contest arose between him and John bishop of Jerusalem. He afterwards called a council in the island of Cyprus, in which he procured a prohibition of the reading of Origen's writings; and made use of all his endeavours to prevail on Theophilus bishop of Alexandria to engage St. Chrysostom to declare in favour of that decree: but not meeting with success, he went himself to Constantinople, where he would not have any conversation with St. Chrysostom; and formed the design of entering the church of the apostles, to publish his condemnation of Origen: but being informed of the danger to which he would be exposed, he resolved to return to Cyprus; but died at sea, in the year 403. His works were printed in Greek, at Basil, 1544, in folio; and were afterwards translated into Latin, in which language they have been often reprinted. Petavius revised and corrected the Greek text by two manuscripts, and published it together with a new translation at Paris in 1622. This edition was reprinted at Cologne in 1682.

EPIRUS (*Encyel.*). This country, according to Josephus, was first peopled by Donanion, the son of Javan and grandson of Japhet. The people were very warlike: but they continued in their savage state long after their neighbours were civilized; whence the Islanders used to threaten their offenders with transportation to Epirus. Their horses were in great request among the ancients, as well as the dogs produced in one of the divisions called *Molossus*; and hence these dogs were called by the Romans *Molossi*.

The history of Epirus commences with the reign of Pyrrhus, the son of Achilles by Deidamia the daughter of Lycomedes king of Scyros. He is said to have behaved with great bravery at the siege of Troy; but it would appear that he behaved with no less barbarity. After the city was taken, he is said to have killed old King Priam with his own hand; to have thrown Aityanax the son of Hector and Andromache headlong

from an high tower; and sacrificed Polyxena the daughter of Priam on the tomb of her father. He carried Andromache with him into Epirus, where he settled by the advice of the famous soothsayer Helenus, one of Priam's sons, who had served during the Trojan war both under his father and himself. The only remarkable period of the history of Epirus is the reign of Pyrrhus II. who made war upon the Romans. He was invited into Italy by the Tarentines; and embarked about 280 B.C. After having escaped many dangers by sea, he landed in that country, and with great difficulty gained a victory over the Romans; but he was afterwards utterly defeated by them, and obliged to return into his own country. To retrieve his honour, he then undertook an expedition against Macedon; where he overthrew Antigonus, and at last made himself master of the whole kingdom. He then formed a design of subduing all the other Grecian states; but met with such an obstinate resistance at Lacedaemon, that he was obliged to drop the enterprise; and was soon after killed at the siege of Argos, by a woman, who from the wall threw a tile upon his head. Deidamia, the grand-daughter of Pyrrhus, was the last that sat on the throne of Epirus. She is said to have been murdered after a short reign; upon which the Epirotes formed themselves into a republic.

Under the new form of government Epirus never made any considerable figure, but seems rather to have been dependent on the kingdom of Macedon. The Romans having conquered Philip king of that country, restored the Epirotes to their ancient liberty; but they, forgetful of this favour, soon after took up arms in favour of Perseus. As a punishment for this ingratitude, the Romans gave orders to Paulus Emilius, after the reduction of Macedon, to plunder the cities of Epirus, and level them with the ground. This was punctually executed throughout the whole country on the same day, and at the same hour. The booty was sold, and each foot-soldier had 200 denarii, that is, six pounds nine shillings and two pence, and each of the horse the double of this sum. An hundred and fifty thousand men were made slaves, and sold to the best bidder for the benefit of the republic. Nor did the vengeance of Rome stop here; all the cities of Epirus, to the number of 70; were dismantled, and the chief men of the country carried to Rome, where they were tried, and most of them condemned to perpetual imprisonment. After this terrible blow, Epirus never recovered its ancient splendor. Upon the dissolution of the Achaean league, it was made part of the province of Macedon; but when Macedon became a diocese, Epirus was made a province of itself, called the province of *Old Epirus*, to distinguish it from *New Epirus*, another province lying to the east of it. On the division of the empire, it fell to the emperors of the East, and continued under them till the taking of Constantinople by the Latins, when Michael Angelus, a prince nearly related to the Greek emperor, seized on Etolia and Epirus, of which he declared himself despot or prince; and was succeeded by his brother Theodorus, who took several towns from the Latins, and so far enlarged his dominions, that, disdaining the title of *despote*, he assumed that of *emperor*, and was crowned by Demetrius archbishop of Bulgaria. Charles, the last prince of this family, dying without lawful issue, bequeathed Epirus and Acarnania to his natural sons, who were driven out by Amurath the Second. Great part of Epirus was afterwards held by the noble family of the Castriots; who, though they were masters of all Albania, yet styled themselves princes of Epirus. Upon the death of the famous George Castriot, surnamed *Scanderbeg*, Epirus fell to the Venetians, who were soon dispossessed of it by the Turks; in whose hands it still continues, being now known by the name of *Albania*, which comprehends the Albania of the ancients, all Epirus, and that part of Dalmatia which is subject to the Turks.

EPISCOPIUS (Simon), one of the most learned men of the 17th century, and the chief supporter of the Arminian sect, was born at Amsterdam in 1583. In 1612 he was chosen divinity professor at Leyden, in the room of Gomarus, who resigned; and the functions of his office, with his private studies, were light burthens to him, compared with the difficulties he sustained on account of the Arminian controversy: which, though it began in the universities, soon flew to the pulpits, from whence it spread and inflamed the people. The states of Holland having invited Episcopius to take his place at the synod of Dort, he went thither accompanied by some remonstrant ministers; but the synod would not allow them to sit as judges, nor to appear in any other capacity than as persons summoned before them: they submitted, were deposed from their functions, and banished the territories of the commonwealth. Episcopius and his persecuted brethren retired to Antwerp; but the times growing more favourable, he returned to Holland in 1626, and was made minister of the church of the Remonstrants at Rotterdam: in 1634, he was chosen rector of the college founded by his sect at Amsterdam, where he spent the remainder of his days. He died in 1643, of the same disorder which had killed his wife before, a retention of urine; having lost his sight some weeks previous to his end. The learned have bestowed great eulogiums on Episcopius; but he did not always write with that moderation which might have been wished. His works make two volumes in folio, of which the second consists of posthumous publications.

EPPING, a town in Essex, with a market on Friday. The butter made in this neighbourhood, and called Epping butter, is highly esteemed in London. Epping is seated at the N. end of a forest of the same name, 17 miles N.N.E. of London. Long. 0. 9. E. Lat. 51. 46. N.

EPING-FOREST, a fine forest in the S.W. of Essex, formerly a much more extensive district, that contained a great part of the county. It then went by the name of the Forest of Essex; and afterwards, when its boundaries had been considerably contracted, it had the name of Waltham Forest, from its vicinity to Waltham Abbey.

EPPINGEN, a town in Germany, in the palatinate of the Rhine, with a castle, seated on the Elfsat, 20 miles N.E. of Philipburg. Long. 9. 0. E. Lat. 49. 24. N.

EPULONES, in Roman antiquity, ministers who assisted at the sacrifices, and had the care of the sacred banquet committed to them.

EPWORTH, a village of the Isle of Axholm, in Lincolnshire, nine miles N. of Gainsborough. It is the birth place of John Wesley, one of the founders of the sect of the methodists.

ERBACH, a town of Franconia, capital of a county of the same name, 16 miles N.N.E. of Heidelberg, and 20 N.E. of Mannheim.

ERIBOL, Loch, an arm of the sea, on the N. coast of Sutherlandshire, capable of affording a safe retreat to the largest vessels. It receives several streams; particularly that which flows from a lake called Loch Hope.

ERICHT, Loch, a lake in the district of Athol, Perthshire. It extends several miles into Invernesshire. Near this place wandered the fugitive Pretender, in 1746, lurking in caves, and among rocks. The waters of this lake descended into another, called Loch Rannoch.

ERISSO, a town of Macedonia, with a bishop's see, at the bottom of the gulf of Monte Sancto.

ERITH, a village in Huntingdonshire, on the Ouse, five miles E.N.E. of St. Ives. Near this place is a piece of antiquity called Belfar's Hill, an artificial mount, generally supposed to be the place where the people took up arms against

William the Norman, in 1066, after he defeated Harold at the battle of Hastings.

ERIVAN, a city and the capital of Persian Armenia, in a province of the same name, with an Armenian patriarch. It is defended by a fortress, in which is the governor's palace, and by a castle, on the river Zengui, near a lake of its own name, which is very deep, and 60 miles in circumference. The Meidan is an open square, 400 paces over, wherein are very fine trees. The baths and caravansaries have their beauties, but the churches of the Christians are small, and half under ground. It is 105 miles N.W. of Astrabad. Long. 44. 10. E. Lat. 40. 20. N.

ERKELENS, a town of Westphalia, in the duchy of Juliers, with a castle, seated on the Roer, 10 miles N.W. of Juliers. Long. 6. 35. E. Lat. 51. 4. N.

ERLANG, a town of Franconia, in the marquisate of Culmbach, seated on the Regnitz, 12 miles N.W. of Nuremberg. Long. 11. 5. E. Lat. 49. 35. N.

ERMELEND, a country surrounded by Prussia, formerly subject only to the bishop and chapter, and called the bishopric of Ermeland, but now become a province of Prussia.

ERNEE, a town of France, in the department of Mayenne, situate on the Mayenne, 15 miles N.N.W. of Laval. Long. 0. 48. W. Lat. 48. 19. N.

ERPACH, a town of Franconia, capital of a county of the same name, with a castle, 30 miles S.E. of Francfort. Long. 0. 10. E. Lat. 40. 32. N.

ERQUIKO, a sea-port of the Red Sea, on the coast of Abex, subject to Turkey. It is 320 miles S.W. of Mecca. Long. 39. 5. E. Lat. 17. 30. N.

ERROMANGO, one of the New Hebrides, in the South Pacific Ocean. Long. 169. 19. E. Lat. 18. 47. S.

ERZERUM, a city of Turkish Armenia, with Armenian and Greek episcopal sees. It is situate between the two sources of the Euphrates, in a beautiful plain, at the foot of a chain of mountains, fruitful in all sorts of corn. It is surrounded by double walls, defended by square towers. The Turks, who are all janissaries, are about 12,000 in number; but most of them are tradesmen, and receive no pay. The Armenians have two churches, the Greeks but one: the latter are mostly braziers, and live in the suburbs. A great trade is carried on here in furs, Persian silks, cottons, calicoes, and drugs. This town is a thoroughfare, and a resting-place for the caravans to the East Indies. It is 104 miles S. by E. of Trebizond. Long. 40. 35. E. Lat. 39. 56. N.

ESCALONA, a town of Spain, in Old Castile, 14 miles N.N.E. of Sagovia.

ESCALONA, a town of Spain, in New Castile, surrounded with walls. It is situate on an eminence, in a fertile country, near the Albreche, 20 miles N.W. of Toledo, and 32 S.W. of Madrid.

ESCAPE, or **FIRE-ESCAPE**, a contrivance for removing persons and their property safely from the upper windows of a house on fire. Several methods of doing this have been suggested by different persons. The following description of a machine for saving persons from the upper stories of a house on fire, by Dr. Collin, appears in the Transactions of the American Philosophical Society, who rewarded the inventor with their gold medal.

A BCC (Plate 27) is a trunk with a socket from top to bottom, and two pulleys *a, a*, in the sides C, C. In this cylindrical shaft DE moves, supported on the pulleys by two ropes. These are by one end tacked to the foot of the shaft, and by the other to the axes of the windlasses I, I, which stand below. The cranks, winding the ropes round the axes, lift the foot of the shaft to the pulleys, and by unwinding let it down to the bottom.

FE $\bar{G}$ is a lever, turning on its fulcrum, which is fixed on the top of the shaft, by the iron tire d . The long arm is pressed by the frame at its end: the short one is held in balance by the rope GH, which is fastened on the base of the machine. As the lever descends with the shaft, the rope slackens on the short arm; then the other, no longer balanced, descends round the fulcrum, and by this motion turns the short one upwards tight against the rope. Their angular contrary movements continue thus, until the shaft reaches the bottom of the socket; and the basket at the same time comes to the ground.

The base is a rectangular plank floor with a compact frame underneath. The trunk is fixed in it, by several braces c , and other usual fastenings, both above and below, stranding somewhat from the centre towards the rope GH, in order to counteract its raising that end.

The windlasses are firmly set in the floor, near the trunk, directly under the pulleys.

The wheels are low and strong, placed near the corner of the base. They have locks, to be used when the machine is loading.

The basket is breast-high, and wide enough for four persons. The three iron rods keep it more steady than cords would; and their openings admit one person at a time. It hangs free from the end of the lever.

The principles of this construction arise from the requisite properties of this machine: it must be speedily brought; readily fitted; practicable in confined places; want no support from the wall; reach a considerable height, and also project over obstacles on or above the ground; take down several persons at once, and without any exertion of theirs. The two vertical pieces folded, with the lever oblique, can both be hoisted and easily carried: when put in action, they expand gradually; and the lever is high when at full length. The base may be convenient, because its own weight, with the trunk and the four men at the windlasses keep the centre of gravity pretty low; and all the pressures bear perpendicular on the longer face. Besides, people may sit down on the sides, or hold it by handspikes, which may be kept on it, and when wanted, put into holes near the margins, so as to project outwards. A level position being very necessary, a plumb rule should also be hung on the trunk.

The cylindrical form of the shaft and socket procures an easy gliding motion, that lessens the occasional sideway bearings. It is also less alterable by wear, and change of weather; it makes the shaft more solid, and thus requires less bulk in both pieces. The two quarters of the trunk which are fit for a communication of the ropes with the shaft, will yet be strong enough by the solid piers that bear the pulleys. The other two have sufficient firmness against oblique pressures, arising from the action of the machine, or from the casual inclination of the base. The part from the brim to the pulleys inclusively is fortified by the iron-band BB, to secure the shaft when drawn up. The height of that piece, its own weight, the pressure on its head, and the obliquity of the frame at the time, together with probable external accidents, will determine the width; it need perhaps not exceed a fifth of the part below.

The trunk and shaft require stiff and hard materials. The lever being made of tough wood, may be further strengthened by iron plates. The solidity and shape of the fulcrum and arms must be carefully proportioned to their respective weights.

The shaft, when down, reaches beyond the trunk so much as to clear the lever of the piers. This added to the distance of the brim from the pulleys, is the difference between the shaft and their height aa . The altitude aE is therefore aa

doubled and that surplus. If the shaft bore a greater proportion in effecting this altitude, it must be longer; consequently it would, when standing, hold the arm further from the ground, and render that piece, with itself, less portable; and, when up, increase the weight on the fulcrum, and the pressure against the socket.

The arm EF rises from aE on an angle about fifty degrees with the horizon, thus making a good projection, and a considerable increase of altitude. Its proportion to the shaft and angle with it when down, are such as to set the basket on the ground.

These angles, the shaft, and the space aa (its elevation), accord in adjusting the proportion of $E\bar{G}$, and the position of the rope. When the lever descends, the arm EG opens and throws out the rope, keeping it stretched all the while. This makes it describe a circular arch. The lever having come to a horizontal position, the arm by the continued rotation returns towards the line aE , and makes the rope retrace the arch until the shaft is down. If the reversed angle of the arm is then equal to $aE\bar{G}$, the rope comes to the point G , from whence it went, if less it goes beyond. In the first case $E\bar{G}$ is the side of a triangle which has aa for its base and two angles equal to $aE\bar{G}$; in the second it is less than this side. As the elevation of EF is not above 50, its complement $aE\bar{G}$ (40) is greater than the angle of EF with the shaft, which with that span would hold the arm too high from the ground. It consequently exceeds the reversed angle, which (being opposite) is equal with this. Therefore the short arm is less than the said side, but the difference is not great.—The situation of the shaft being most critical in the highest elevation, the rope should then allow the lever very moderate rotation, and thus lessen the kicking of the weight against the fulcrum. Its position will therefore be nearly perpendicular, when the descent begins, that the arch, immediately falling, or rising very little, may keep down the end of $E\bar{G}$. This position requires a moderate elevation of EF, for if the angle $DE\bar{G}$ is too contracted, $E\bar{G}$ will project far beyond the foot of the rope, in and about its horizontal passage; and thus produce a detrimental obliquity. It also limits the fall of EF, by regulating the reversed angle; for the nearer the point G returns to the shaft, the further it goes from the rope, and the more oblique is the outward draught.

The obliquity of draught admitted in this machine, appears easy on the model: trials may prove a greater elevation of the lever practicable. The proportion of the short arm is sufficient while the whole weight to be wound up does not exceed that of twelve persons: for so much, at least, four hands at the windlasses are competent. If the rope is drawn by hands, this arm must still, for the sake of convenient carriage, be much shorter than the other; and accidents of mismanagement might happen, which the fixed rope prevents: it is prudent to adjust the machine with all the powers it can exercise; especially as it must be used on the dismal occasion of nocturnal conflagrations.

In considerable towns the houses differ so much in height, that machines of two sizes are necessary. The larger should be competent for the third or fourth stories in the highest buildings, according to their dimensions, and the practicable size of the three pieces; and the smaller for those in the lowest. As both have several degrees of elevation, they will also suit inferior stories respectively, and thus take in all the different heights. The basket must ascend so near beneath the window, that the persons may, without fear, get in, and descend so low that they may get out. For the last arm cannot be long enough, when great altitudes demand very high shafts; then a rope ladder may be fixed on the basket, and let down when the machine stops; ten feet from the ground,

if necessary. As the dimensions of the lever and shaft of large machines demand great solidity, their weight will bear a considerable proportion of the whole that is wound up. One or two persons more in the basket would proportionably less increase the whole. Their bafes will also be wide enough for two men at each of the four cranks. The smaller machines must support the weight of four full-grown persons, as the fire may prevent a second going up. Their bafes are to be fitted for narrow alleys, and crowded places.

Much property might be saved from the fire by machines of a similar construction with this, having a capacious basket, and capstans instead of windlasses. The combination of perpendicular and lateral movements may also be applied to many other valuable purposes.

Perpendicular lines being dropped from the point G to the bafe, the squares of these, and the squares of the distances of their ends from the foot of the rope, are jointly equal to the square of the rope. The square of EG is likewise equal to those of its lines. When the shaft is drawn up, the perpendicular height of the rope differs from the joint heights of the shaft and pulleys by the cosine of DEG; and when the shaft is down, it is equal to the height of this piece, joined to the cosine of the reversed angle. The sines of these angles are equal to the distances between the ends of the said perpendiculars and the centre of the trunk's bottom. Taking the value of the rope in the two cases, gives this equation:

$$\begin{aligned} a^2 + 2 \text{ shaft} \times a a &= \\ 2 a E \times \cos. DE & \\ + 2 f h \times \cos. \text{rev. ang.} & \\ + 2 a H \times \sin. DEG - \sin. \text{rev. a.} & \end{aligned} \quad \left. \begin{array}{l} \\ \\ \\ \end{array} \right\} EG.$$

This will guide the choice of angles, proportion of EG, and position of the rope.

ESCAPEMENT (*Encycl.*), a part of the machinery of a watch. See WATCH. The following description of a new escapement for watches appears in the Transactions of the Society for the Encouragement of Arts, Manufactures, and Commerce; and thirty guineas were voted to Mr. De LaFont for this invention.

"Having considered the perfection of chronometers," says the author, "to consist more in giving an equal impulse to the balance than to any other general cause, I present to the society the model of a new escapement, which has not only the property of correcting the errors of the main-spring, train of wheels, &c. and giving an equal power to the balance, but likewise the wheels are locked, without spring-work, perfectly safe from getting out of order, and are unlocked with less power than in any escapement I know, as the wheels do not bear against the locking with more than a tenth part of the whole pressure from the main-spring; a circumstance I believe to be perfectly new.

"Although the giving an equal impulse to the balance has been already most ingeniously done by Mr. Mudge and Mr. Haley (from whose great merit I would not wish to detract), yet the extreme difficulty and expence attending the first, and the very compound locking of the second, render them far from completing the desired object.

"The perfections and advantages arising from my improvements on the remontoire detached escapement for chronometers, which gives a perfectly equal impulse to the balance, and not only entirely removes whatever irregularities arise from the different states of fluidity in the oil, from the train of wheels, or from the main-spring, but does it in a simpler way than any with which I am acquainted. I trust it will not be thought improper in me to answer some objections made at the examinations before the committee, as I am fully persuaded the more mathematically and critically the improvements are investigated, the more perfect they will prove to be.

"It was first observed, that my method did not so completely detach the train of wheels from the balance as another escapement then referred to. I beg leave to remark, that the train of wheels in mine is prevented from pressing against the locking, by the whole power of the remontoire-spring; so that the balance has only to remove the small remaining pressure, which does away that objection, and also that of the disadvantage of detents, as this locking may be compared to a light balance turning on five pivots, without a pendulum-spring; and has not only the advantage of banking safe at two turns of the balance, and of being firmer, and less liable to be out of repair than any locking where spring-work is used, but likewise of unlocking with much less power.—It was then observed, it required more power to make it go than usual. Permit me to say, it requires no more power than any other remontoire escapement, as the power is applied in the most mechanical manner possible.—And, lastly, it was said, that it set or required the balance to vibrate an unusually large arch before the piece would go. This depends on the accuracy of the execution, the proportionate diameter and weight of the balance, the strength of the remontoire-spring, and the length of the pallets. If these circumstances are well attended to, it will let but little more than the most generally detached escapements."

In plate 26, A. shews the escape-wheel.

B. the level pallet, on an arbor with fine pivots, having at the lower end.

C. The remontoire or spiral spring fixed with a collar and stud, as pendulum-springs are.

D. The pallet of the verge, having a roller turning in small pivots for the lever pallet to act against.

E. Pallets to discharge the locking; with a roller between, as in fig. 4.

F. The arm of the locking pallet continued at the other end to make it poise, having studs and screws to adjust and bank the quantity of motion.

a and b. The locking pallets, being portions of circles, fastened on an arbor turning on fine pivots.

G. The triple fork, at the end of the arm of the locking pallets.

The centre of the lever-pallet in the draft, is in a right line between the centre of the scape-wheel and the centre of the verge, though in the model it is not: but may be made so or not, as best suits the calliper, &c.

The scape-wheel A, with the tooth 1, is acting on the lever-pallet B, and has wound up the spring C; the verge-pallet D (turning the way represented by the arrow) the moment it comes within the reach of the level pallet, the discharging pallet E, taking hold of one prong of the fork, removes the arm F, and relieves the tooth 3 from the convex part of the lock a. The wheel goes forward a little, just sufficient to permit the lever-pallet to pass, while the other end gives the impulse to the balance: the tooth 4 of the wheel is then locked on the concave side of the lock b, and the lever-pallet is stopped against the tooth 5, as in fig. 3. So far the operation of giving the impulse, in order again to wind the remontoire-spring (the other pallet at E, in the return, removing the arm F the contrary direction), relieves the tooth 3 from the lock b. The wheel again goes forward, almost the whole space, from tooth to tooth, winds the spiral-spring again, and comes into the situation of fig. 1, and thus the whole performance is completed. The end of the lower pallet B resting on the point of the tooth 1, prevents the wheel exerting its full force on the lock a, as in fig. 1. The same effect is produced by the pallet laying on the tooth 5, by preventing the wheel from pressing on b; and thus the locking becomes the tightest possible. This escapement may be much simplified by putting a spring with a pallet made in it, as in fig. 5, instead of the lever-pal-

let, and spiral-spring. The operation will be in other respects exactly the same, avoiding the friction of the pivots of the lever-pallet. This method I prefer for a piece to be in a state of rest, as a clock; but the disadvantage, from the weight of the spring in different positions, is obvious.

The locking may be on any two teeth of the wheel, as may be found most convenient.

ESCHELLES, a town of Savoy, on the frontiers of Dauphiny, 10 miles S.W. of Chambery. Long. 5. 45. E. Lat. 45. 30. N.

ESCHWEGEN, a town of Germany, in the Landgrave of Hesse-Cassel, seated on the Werra, 22 miles S.E. of Hesse-Cassel. Long. 10. 6. E. Lat. 51. 9. N.

ESCHWEILER, a town of Westphalia, in the duchy of Juliers, 6 miles S. of Juliers.

ESENS, a town of Westphalia, in East Friesland, on the German Ocean, 20 miles N. of Embden. Long. 7. 14. E. Lat. 53. 47. N.

ESFARAIN, a town of Persia, in Korasan, famous for the great number of writers it has produced. It is 90 miles E. of Afrabad. Long. 41. 23. E. Lat. 36. 48. N.

ESGUEYRA, or **ESCUERIA**, a town of Portugal, in Beira, eight miles S. of Aveiro.

ESHER, a village in Surrey, on the river Mole, five miles S.W. of Kingston. It is distinguished by a noble Gothic mansion, the two towers of which are as they were originally built by Cardinal Wolsey.

ESKDALE, the most easterly division of Dumfriesshire, so named from the river Esk, which flows through it, in a course of 20 miles, to the town of Langholm.

ESKISHEHR, a town of Natolia, on the river Sakaria, 176 miles S.E. of Constantinople. Long. 30. 58. E. Lat. 39. 48. N.

ESLINGEN, a large Imperial city of Suabia, in the duchy of Wirtemberg. Here are several convents, but the inhabitants are chiefly Protestants. It is seated on the Neckar, eight miles S.E. of Stutgard. Long. 9. 20. E. Lat. 48. 47. N.

ESOPUS, a town of the state of New York, on a river of the same name, 76 miles N. of New York.

ESPALION, a town of France, in the department of Aveiron, 14 miles N.N.E. of Rhodéz. Long. 2. 40. E. Lat. 43. 32. N.

ESPERIE, a town of Hungary, near which are some famous salt mines. It is 22 miles N. of Cschaw. Long. 21. 38. E. Lat. 49. 5. N.

ESPERNON, a town of France in the department of Eure and Loire, seated on the Gueule, 12 miles N.E. of Chartres. Long. 1. 44. E. Lat. 48. 36. N.

ESPIERS, a town of Austrian Flanders, where a river of the same name falls into the Scheld, eight miles N. of Tournay. Long. 3. 25. E. Lat. 50. 53. N.

ESPOSENDA, a sea-port of Portugal, in Entre-Duero-e-Minho, at the mouth of the Cavado, 22 miles N. of Oporto, Long. 8. 21. W. Lat. 41. 32. E.

ESSECK, a trading town of Sclavonia, with a strong castle. It has a bridge over the marshes, 8865 geometrical paces in length and 15 in breadth, with towers at a quarter of a mile distant from each other, and handiomey raised on each side. It is a difficult pass, and there have been several battles fought here between the Turks and Germans. There are trees in all the streets of the town, which was taken from the Turks in 1687, since which time it has continued in the hands of the house of Austria. It is seated on the river Drave, 80 miles W. by N. of Belgrade, and 175 S. by E. of Vienna. Long. 19. 58. E. Lat. 45. 40. N.

ESSEN, a town of Westphalia in the duchy of Cleves, formerly Imperial, but now subject to the abbots of Essen.

It is eight miles E. of Duisburg. Long. 7. 4. E. Lat. 51. 22. N.

ESTAPO, a strong town of New Spain, seated at the mouth of the river Tlaluc, 230 miles S.W. of Mexico. Long. 103. 5. W. Lat. 17. 30. N.

ESTAVAYER, a town and bailiwick of Switzerland, in the canton of Friburg, on the borders of the lake of Neuchatel, with a fine castle. In the 15th century it belonged to the duke of Savoy, who, taking part against the Swiss, they besieged and sacked the town in 1473. It is 13 miles W. of Friburg. Long. 6. 56. E. Lat. 46. 55. N.

ESTE, a town of Italy, in the Paduan, 15 miles S.W. of Padua. Long. 12. 44. E. Lat. 45. 55. N.

ESTELLA, an episcopal town of Spain, in Navarre, capital of the territory of the same name; seated on the Ega, 15 miles W. of Pampeluna. Long. 2. 0. W. Lat. 42. 40. N.

ESTEPA, a town of Spain, in Andalusia, with an ancient castle, on a mountain, 62 miles N. by W. of Malaga. Long. 4. 19. W. Lat. 37. 16. N.

ESTEPONA, a town of Spain, in Granada, near the coast, 20 miles W.S.W. of Marbella.

ESTHWAITE-WATER, a lake in Lancashire, between Hawkhead and Windermere Water. It is two miles and a half long, and half a mile broad, intersected by a peninsula from each side, jutting far into the lake. On the banks are villages and scattered houses, pleasantly situated under woods, and hanging grounds, clothed with verdure; all heightened by the deep shade of the woods, and the strong back-ground of rocky mountains. At the head of a gentle slope, a handsome modern house, called Belmont, commands a delightful view of the lake and its environs. The fish are pike, perch, eel, and trout; but no char is found in this lake, though it is connected with Windermere-water.

ESTREMOS, a town of Portugal, in Alentejo, divided into the upper town and the lower. The upper is commanded by a citadel, on the top of a hill, strongly fortified, and surrounded by a large ditch. The houses are white, and the principal are adorned with fine marble pillars: there is also a tower of marble, finely polished. The lower town is the newest, and has a large square, in the middle of which is a basin. An earthen-ware is made here, greatly esteemed for its beauty and fine smell. The Portuguese gained a complete victory over Don John of Austria near this place, 1763. It is seated on the river Terra, which falls into the Tago, 15 miles W. of Badajoz, and 75 E. of Lisbon. Long. 7. 16. W. Lat. 38. 44. N.

ESWEGEN, a town of Germany, in the landgrave of Hesse Cassel, 25 miles S.E. of Cassel. Long. 10. 9. E. Lat. 51. 11. N.

ETAINE, a town of France, in the department of Meuse, 15 miles N.E. of Verdun. Long. 5. 35. E. Lat. 49. 15. N.

ETAMPES, a town of France, in the department of Seine and Oise, seated on the river Olet or Etampes, which abounds with cray-fish. It is 15 miles E. of Chartres. Long. 2. 10. E. Lat. 48. 30. N.

ETAPLES, a sea-port of France, in the department of the Straits of Calais; situate near the mouth of the Canche, 23 miles S. of Boulogne. Long. 1. 56. E. Lat. 50. 46. N.

ETAYA, a town of Hindoostan Proper, in the province of Agra, situate on a high bank of the Jumna. Many parts of the bank are 60 feet high, the sides of which consist of what in India is called concha, which is originally sand; but the constant action of the sun, in the dry season, forms it almost into a vitrification. On the top, near the river, are the remains of a fort. The town is large, but very wretched, having but two tolerable houses. It is 62 miles S.E. of Agra. Long. 79. 25. E. Lat. 26. 43. N.

ETHIOPIA, a name by which a vast region of Africa has been distinguished by some geographers, who have divided it into Upper and Lower Ethiopia. The first includes Abyssinia and Nubia; the second all the countries of the equinoctial line; as far as Lower Guinea, Monomugi, Monomotapa, &c.

ETIENNE (Str.), a city of France, in the department of Rhone and Loire, remarkable for its manufactures in iron and steel, for the tempering of which the water of the brook Eurens, on which it is seated, is extremely good. Beside the manufacture of arms, hardware, and cutlery (the most considerable in France), the weaving of ribands forms a considerable article of its commerce. Coal is found in its neighbourhood, and also a soft stone fit for grind-stones. Its merchandise is conveyed to Paris, Nantes, and Donkirk, by the Loire, which begins to be navigable for small barges at St. Lambero. St. Etienne is 22 miles S.E. of Fuers, and 260 S. by E. of Paris. Long. 4. 30. E. Lat. 45. 22. N.

ETLINGEN, an ancient town of Suabia, in the margravate of Baden-Dourlach, seated at the confluence of the Wirim and Entz, three miles S. of Dourlach, Long. 9. 30. E. Lat. 48. 59. N.

ETOLIA (*Encycl.*). The Etolians were a restless and turbulent people; seldom at peace among themselves, and ever at war with their neighbours; utter strangers to all sense of friendship, or principles of honour; ready to betray their friends upon the least prospect of reaping any advantage from their treachery; in short, they were looked upon by the other states of Greece no otherwise than as outlaws and public robbers. On the other hand, they were bold and enterprising in war; inured to labour and hardships; undaunted in the greatest dangers; jealous defenders of their liberties, for which they were on all occasions willing to venture their lives, and sacrifice all that was most dear to them. They distinguished themselves above all the other nations of Greece, in opposing the ambitious designs of the Macedonian princes; who, after having reduced most of the other states, were forced to grant them a peace upon very honourable terms. The constitution of the Etolian republic was copied from that of the Achæans, and with a view to form, as it were, a counter alliance; for the Etolians bore an irreconcilable hatred to the Achæans, and had conceived no small jealousy at the growing power of that state. The Cleonic war, and that of the allies, called the *social war*, were kindled by the Etolians in the heart of Peloponnesus, with no other view but to humble their antagonists the Achæans. In the latter, they held out, with the assistance only of the Eleans and Lacedæmonians, for the space of three years, against the united forces of Achæa and Macedon; but were obliged at last to purchase a peace, by yielding up to Philip all Acarnania. As they parted with this province much against their will, they watched all opportunities of wresting it again out of the Macedonian's hands; for which reason they entered into an alliance with Rome against him, and proved of great service to the Romans in their war with him; but growing insolent upon account of their services, they made war upon the Romans themselves. By that warlike nation they were overcome, and granted a peace on the following severe terms: 1. The majesty of the Roman people shall be revered in all Etolia. 2. Etolia shall not suffer the armies of such as are at war with Rome to pass through her territories, and the enemies of Rome shall be likewise the enemies of Etolia. 3. She shall, in the space of 100 days, put into the hands of the magistrates of Corcyra all the prisoners and deserters she has, whether of the Romans or their allies, except such as have been taken twice, or during her alliance with Rome. 4. The Etolians shall pay down in ready money, to the Roman general in Etolia, 200 Euboic talents, of the same value as

the Athenian talents, and engage to pay 50 talents more within the six years following. 5. They shall put into the hands of the consul 40 such hostages as he shall choose; none of whom shall be under 12, or above 40, years of age; the pretor, the general of the horse, and such as have been already hostages at Rome, are excepted out of this number. 6. Etolia shall renounce all pretensions to the cities and territories which the Romans have conquered, though those cities and territories had formerly belonged to the Etolians. 7. The city of Oenis, and its district, shall be subject to the Acarnanians.

After the conquest of Macedon by Paulus Æmilius, they were reduced to a much worse condition; for not only those among them, who had openly declared for Perseus, but such as were only suspected to have favoured him in their hearts, were sent to Rome, in order to clear themselves before the senate. There they were detained, and never afterwards suffered to return to their native country. Five hundred and fifty of the chief men of the nation were barbarously assassinated by the partisans of Rome, for no other crime but that of being suspected to wish well to Perseus. The Etolians appeared before Paulus Æmilius in mourning habits, and made loud complaints of such inhuman treatment; but could obtain no redress: nay, ten commissioners, who had been sent by the senate to settle the affairs of Greece, enacted a decree, declaring, that those who were killed had suffered justly, since it appeared to them that they had favoured the Macedonian party. From this time those only were raised to the chief honours and employments in the Etolian republic, who were known to prefer the interest of Rome to that of their country; and as these alone were countenanced at Rome, all the magistrates of Etolia were the creatures and mere tools of the Roman senate. In this state of servile subjection they continued till the destruction of Corinth, and the dissolution of the Achæan league; when Etolia, with the other free states of Greece, was reduced to a Roman province, commonly called the *province of Achæa*. Nevertheless, each state and city was governed by its own laws, under the superintendency of the pretor, whom Rome sent annually into Achæa. The whole nation paid a certain tribute, and the rich were forbidden to possess lands any-where but in their own country.

In this state, with little alteration, Etolia continued under the emperors, till the reign of Constantine the Great, who, in his new partition of the provinces of the empire, divided the western parts of Greece from the rest, calling them *Nova Epirus*, and subjecting the whole country to the *prefectus prætorii* for Illyricum. Under the successors of Constantine, Greece was parcelled out into several principalities, especially after the taking of Constantinople by the western princes. At that time, Theodorus Angelus, a noble Grecian, of the imperial family, seized on Etolia and Epirus. The former he left to Michael his son; who maintained it against Michael Palæologus, the first emperor of the Greeks, after the expulsion of the Latins. Charles, the last prince of this family, dying in 1430, without lawful issue, bequeathed Etolia to his brother's son, named also Charles; and Acarnania to his natural sons, Memnon, Turnus, and Hercules. But, great disputes arising about this division, Amurath II. after the reduction of Thessalonica, laid hold of so favourable an opportunity, and drove them all out in 1432. The Mahometans were afterwards dispossessed of this country by the famous prince of Epirus, George Castriot, commonly called *Scanderbeg*; who, with a small army, opposed the whole power of the Ottoman empire, and defeated those barbarians in 22 pitched battles. This hero, at his death, left great part of Etolia to the Venetians; but they not being able to make head against such a mighty power, the whole country was

soon reduced by Mohammed II. whose successors hold it to this day.

ETTENHEIM, a town of Germany, in the bishopric of Strasburg, 15 miles N. of Friburg, and 19 S.S.E. of Strasburg. Long. 7. 26. E. Lat. 48. 25. N.

ETTILINGEN, or **ETTINGEN**, a town of Suabia, on the Albe, six miles S.S.W. of Dourlach. Long. 9. 26. E. Lat. 48. 58. N.

ETTRICK, a river in Selkirkshire, which rises from the mountainous region in the S.W. and having formed a junction with the Yarrow, their united streams meet the Tweed, where that river enters Roxburghshire. From the woods, formerly on the banks of this river, the county obtained the name of Ettrick Forest. Ettrick Banks are the subject of a pastoral Scotch ditty.

EU, a sea-port of France, in the department of Lower Seine, with a strong castle, and a handsome square. The principal trade is in ferges and lace. It is seated in a valley, on the river Brele, 15 miles N.E. of Dieppe. Long. 1. 30. E. Lat. 50. 3. N.

EVAPORATION (*Encycl.*). In addition to what has been said on this subject, we purpose to give the experiments on evaporation made by Dr. Wistar, an account of which appears in the Transactions of the American Philosophical Society.

"In an essay published in the last volume of the Transactions of the Society," says the doctor, "I described a species of evaporation which was excited by suspending ice, at the melting point, in air reduced to the temperature of 0° of Fahrenheit's scale; and considered as the effect of a general law of nature, in consequence of which an inelastic vapour (which commonly is visible) arises from water, and from wet substances, whenever they are warmer than the atmosphere which surrounds them.

"From facts stated in the same paper it was inferred, that this inelastic vapour does not depend upon any positive quantity or degree of sensible heat in the evaporating body, but upon a relative degree; exceeding that of the atmosphere to which it is exposed; and that it is produced by the passage of heat from the moist body into the contiguous air.—If this theory be true, it follows that a slow distillation may be performed, with the common apparatus, by applying cold to the receiver or refrigeratory, without increasing the heat of the retort or substance to be distilled, as there will be a continual passage of heat from the body to be evaporated or distilled, into the air of the receiver.

"Although, for the reasons there given, I had no doubt of the truth of the doctrine advanced in my former paper, I was desirous of submitting it to the test of this experiment, because it has been suggested that the vapour which appeared to arise from ice might have risen from the mixture of different proportions of air of different temperatures: whereas by distilling or evaporating in a luted retort and receiver, there can be no mixture of warm and cold air; and by using a substance which is not contained in the atmosphere, we shall avoid all suspicion that the vapour which arises from it may have originated from the air in the vessels.

"With these views I poured an ounce and half of vitriolic ether into a retort, and luted it to a receiver with a long neck, which was placed in a mixture of salt and snow, while the retort was surrounded by air of the temperature of 50° of Fahrenheit. The frigorific mixture, from the impurity of the salt, was seldom below 10°, so that the difference between the ether in the retort and the air in the receiver did not exceed 40°.

"When the apparatus had been thirty hours in this situation the frigorific mixture was removed, and one-third of the ether was found distilled into the receiver.

"I believe no cause can be assigned for this distillation but the passage of heat through the ether into the cold air of the receiver; and to be certain that the application of cold to the receiver really produced it, I prepared a similar distilling apparatus, in the same manner precisely, and placed the retort in contact with that of the other apparatus, while the receiver, instead of being chilled by the cold mixture, stood in air of the same temperature with the retorts, viz. 50°; but no distillation took place during thirty hours.

"To vary the experiment, I placed some camphor in another apparatus prepared as above, and fixed the receiver in the frigorific mixture, while the retort stood in air of the temperature of 50°; at the expiration of thirty hours some of the camphor was found sublimed, and the sublimate had those arborescent appearances which usually attend it when produced by heat."

EVAUX, a town of France, in the department of Creuse, 20 miles from Mount Laçon. Long. 2. 55. E. Lat. 46. 12. N.

EUDIOMETER (*Encycl.*). When it was discovered that common atmospheric air contained about 21 parts of vital air, or oxygen, and 79 of azote, or nitrogen, in 100 by measure; it was hastily concluded by physiologists, that we had acquired a power of ascertaining the comparative salubrity of atmospheric air, during different winds, and in different places. For it was believed that the salubrity was proportional to the quantity of oxygen, and that this quantity admitted of considerable variation in different situations. It was however soon found, by the experiments of Dr. Priestley and Mr. Cavendish, and since confirmed by many others, that the air of open seas, or the tops of high mountains, does not differ considerably, in the proportion of those constituents, from that of the streets of London. But when we say the streets of London, we do not mean to include the rooms, theatres, exhibitions, &c. where either respiration or combustion, or both, are going on. This source of contaminated air is, however, by no means confined to the metropolis; for wherever well-jointed fashies, double doors, double windows, or any other means of excluding fresh supplies of air from inhabited rooms, are employed, there a deterioration of it must take place. The means of analyzing and correcting the water we use, are generally known; but the best means of ascertaining the proportion of oxygen contained in the air we breathe, is known only to a few chemists. We shall, therefore, present our readers with Mr. Davy's new Eudiometer, an account of which appears in the Journals of the Royal Institution:

"The dependence (he says) of the health and existence of animals upon a peculiar state of the atmosphere, and the relations of this state to processes connected with the most essential wants of life, have given interest and importance to enquiries concerning the composition and properties of atmospheric air.

"This elastic fluid has been long known to consist chiefly of oxygen and nitrogen, mingled together, or in a state of loose combination, and holding in solution water.

"A variety of processes have been instituted, with the view of determining the relative proportion of the two gases, but most of them have involved sources of inaccuracy; and lately, all, except two (the slow combustion of phosphorus, and the action of liquid sulphurets), have been generally abandoned.

"Both phosphorus and solution of sulphuret of potash absorb the whole of the oxygen of atmospheric air at common temperatures, and they do not materially alter the volume, or the properties of the residual nitrogen; but their operation is extremely slow; and in many cases it is difficult to ascertain the period at which the experiment is completed.

"I have lately employed as an eudiometrical substance the solution of green muriat, or sulphat, of iron, impregnated with nitrous gas; and I have found that it is in some respects superior to many of the bodies heretofore used, as it rapidly condenses oxygen without acting upon nitrogen, and requires for its application only a very simple and a very portable apparatus.

"This fluid is made by transmitting nitrous gas through green muriat, or sulphat, of iron, dissolved to saturation in water. As the gas is absorbed, the solution becomes of a deep olive brown, and when the impregnation is completed it appears opaque and almost black. The process is apparently owing to a simple elective attraction; in no case is the gas decomposed; and under the exhausted receiver it assumes its elastic form, leaving the fluid with which it was combined unaltered in its properties.

"The instruments necessary for ascertaining the composition of the atmosphere, by means of impregnated solutions, consist simply of a small graduated tube, having its capacity divided into one hundred parts, and greatest at the open end; and of a vessel for containing the fluid.

"The tube, after being filled with the air to be examined, is introduced into the solution; and, that the action may be more rapid, gently moved from a perpendicular towards a horizontal position. Under these circumstances the air is rapidly diminished; and, in consequence of the dark colour of the fluid, it is easy to discover the quantity of absorption. In a few minutes the experiment is completed, and the whole of the oxygen condensed by the nitrous gas in the solution in the form of nitrous acid.

"In all eudiometrical processes with impregnated solutions, the period at which the diminution is at a stand must be accurately observed; for, shortly after this period, the volume of the residual gas begins to be a little increased, and, after some hours, it will often fill a space greater by several of the hundred parts on the scale of the tube, than that which it occupied at the maximum of absorption.

"This circumstance depends upon the slow decomposition of the nitrous acid (formed during the experiment), by the green oxide of iron, and the consequent production of a small quantity of ætiform fluid (chiefly nitrous gas)*; which, having no affinity for the red muriate, or sulphate, of iron produced, is gradually evolved, and mingled with the residual nitrogen.

"The impregnated solution with green muriate is more rapid in its operation than the solution with green sulphate. In cases when these salts cannot be contained in a state of absolute purity, the common or mixed sulphate of iron may be employed. One cubic inch of moderately strong impregnated solution is capable of absorbing five or six cubic inches of oxygen, in common processes: but the same quantity must never be employed for more than one experiment.

"A number of comparative experiments, made on the constitution of the atmosphere at the Hotwells, Bristol, in

July, August, and September, 1800, with phosphorus, sulphurets of alkalies, and impregnated solution, demonstrated the accuracy of the processes in which the last substance was properly employed. The diminutions given by the sulphurets were indeed always greater by a minute quantity than those produced by phosphorus and impregnated solutions: but the reason of this will be obvious to those who have studied the subject of Eudiometry. In no instance was it found that 100 parts in a volume of air contained more than 21 of oxygen: and the variations connected with different winds, and different states of temperature, moisture, &c. were too small, and too often related to accidental circumstances, to be accurately noticed.

In analysing the atmosphere in different places, by means of impregnated solutions, I have never been able to ascertain any notable difference in the proportions of its constituent parts. Air, collected on the sea at the mouth of the Severn, on October the 3d, 1800, which must have passed over much of the Atlantic, as the wind was blowing strong from the west, was found to contain 21 per cent of oxygen in volume; and this was nearly the proportion in air sent from the coast of Guinea to Dr. Beddoes, by two furgeons of Liverpool.

"If we compare these results with the results gained more than twenty years ago by Mr. Cavendish, from experiments on the composition of atmospheric air, made at London and Kensington; considering, at the same time, the researches of Berthollet in Egypt, and at Paris, and those of Marti in Spain; we shall find strong reasons for concluding, that the atmosphere, in all places exposed to the influence of the winds, contains very nearly the same proportions of oxygen and nitrogen: a circumstance of great importance; for, by teaching us that the different degrees of salubrity of air do not depend upon differences in the quantities of its principal constituent parts, it ought to induce us to institute researches concerning the different substances capable of being dissolved or suspended in air, which are noxious to the human constitution; particularly as an accurate knowledge of their nature and properties would probably enable us, in a great measure, to guard against, or destroy, their baneful effects.

"The most obvious impregnation of the atmosphere is that with distilled water; and many people have taken up an opinion, that, independent of *miasmata*, the only noxious qualities of the atmosphere depend on its moisture, or the quantity of water diffused through it, when the thermometer is near 32°, or, as they express it, "when cold and moisture are combined; but we shall endeavour to shew, on some future occasion, that this opinion is not well founded."

Cit. Berthollet has made several observations relating to Eudiometry, in a memoir presented to the National Institute of France. The celebrated Mr. Humboldt having examined and compared the different substances employed for knowing the quantity of oxygen contained in a given quantity of atmospheric air, gave the preference to the nitrous gas, which has been proposed by Fontana, as absorbing the oxygen better than other substances employed for the same purpose. It contains, however, sometimes a greater or less quantity of azote, which renders its effect not so sure; a circumstance which may be remedied, after the repeated experiments of Mr. Humboldt, by washing the gas intended for use with a solu-

* The decomposition of nitrous acid, by solutions containing oxide of iron, at its minimum of oxidation, is a very complex process. The green oxide, during its conversion into red oxide, not only decomposes the acid, but likewise acts upon the water of the solution; and ammoniac is sometimes formed, and small portions of nitrous oxide and nitrogen evolved with the nitrous gas.

tion of sulphat of iron, which absorbs all the nitrous gas, but not the azote that is mixed with it. It is this action of the sulphat of iron that Cit. Berthollet has examined; and he has found, that in this case, the nitrous gas is not only absorbed, but decomposed, and by being deprived of a part of its azote, it is changed into nitrous acid. He thinks, on the whole, that the nitrous gas may differ in the proportions of its two principles, the oxygen and the azote, but that it never contains the azote in simple mixture.

The following experiments with the Eudiometer, made at Martinique, by Dr. Davidson, were communicated to Dr. Mitchell, in a letter dated Fort Royal, April 7th, 1798.

"There is," says he, "a large proportion of oxygen, contained in the atmospheric air within the tropics. With equal measures of nitrous air, obtained from brass wire and atmospheric air, there was an absorption of 67.100; but with two measures of atmospheric air, there was somewhat less, from 52.100, to 58.100, that is to say, from three measures, or three hundred parts, there were left two and 42.100, to 48.100. I have also tried a mixture of sulphur and iron filings, in a cylindrical glass tube, and found above four-tenths of the air diminished. As those experiments were made in the presence of a number of medical gentlemen, who have certified the fact, as they have observed it themselves, I can therefore with confidence speak to the result of our experiments.

"We shall now be more easily able to account for the speedy rusting of metals, without having recourse to the action of supposed muriatic foda dissolved in the air. The rancidity of oils, and the speedy fermentation of vinous liquors, may, perhaps, be also owing to the greater heat of the climate; but metals would be less apt to contract rust from the greater heat, if the air contained only the proportion of oxygen, which it contains in Europe. Consumptions here are also more quickly fatal than they are in Europe. On some of the West-India islands, such as Barbadoes and Antigua, where less rain falls, and where the heat of the air is kept at a steady temperature by their smallness, and the trade-winds blowing over the whole island, without being diverted by high or woody land, consumptions are not less fatal than in the larger and moister islands. This is a fact, of which all writers upon diseases of the West Indies take notice; and which we would principally endeavour to account for, from the air being more highly charged with oxygen, than it is in Europe. If people labouring under pulmonary consumption, are sometimes benefited by sea voyages within the tropics, we are to look for the temporary relief afforded, in the sea-sickness; the irritable state of the stomach, by sympathy preventing the lungs acting in decomposing and absorbing oxygen; and in the determination to the surface carrying off the redundancy by the skin. Their costive habit, whilst at sea, proves that there is more than usual determination to the surface—hence relief to the lungs."

Certificates of these facts are subjoined, with the signatures of Dr. Chisholme, and other respectable persons.

Among the articles contained in the extracts lately published from the Memoirs of the School of Medicine at Paris, we find an ingenious essay by Citizen Jurine, with observations by Citizen Seguin, on the following important question:

"What advantages can medicine derive from the modern discoveries in the art of ascertaining the purity of the air, by the different eudiometers?"

Citizen Jurine's memoir, which gained the prize in 1787, is divided into four parts: 1. The first relates to the modification of atmospheric air by respiration. 2. The second treats of the air which is exhaled by the skin, and of the nature of ambient air in different diseases. 3. The third ex-

plains the difference of atmospherical air, the air of hospitals and sick rooms. We shall examine each of these sections of Cit. Jurine's works successively, taking notice at the same time of the principal observations made by Seguin.

In the first place, Jurine remarks on the opinions, the views, and the several discoveries of Priestley, the Abbé Fontana, Scheele, Bergmann, and Morozzo, and the solid and luminous theory of Lavoisier and Laplace. He next explains the extent and capacity of the lungs, after Hales and Jurine. Afterwards he analyzes the air expired in different circumstances of life and health. The means of analysis were lime water, nitrous gas, and the flame of a wax candle.

Experiments were in the first place made to ascertain the difference relative to age, sex, the state of fasting, and the effect of digestion. The air produced by the most complete expiration was then divided into four parts, and successively submitted to a comparative analysis. The other experiments were intended to ascertain the changes produced in the air expired in fever, the last stage of consumption, blood-letting, respiration in pure oxygen, or in air rendered less respirable from previous respiration. Citizen Halle having already published a part of the results of these experiments, under the article *Air* in the *Dictionnaire de Médecine, de l'Encyclopédie Méth.* it is unnecessary to repeat them. To this first part of Citizen Jurine's memoir, Citizen Seguin directs his principal objections, which directly attack the accuracy of the eudiometers, the lime water, and nitrous gas, employed.

In the second part, Citizen Jurin explains several experiments made upon himself, the results of which were, that he disengaged a certain quantity of carbonic gas by the skin. Citizen Seguin thinks, on the contrary, that the carbonic gas does not issue through the skin, but is only that formed by the act of respiration, which, defending by its specific weight, in the bath where the Geneveve physiologist made his experiments, had displaced the atmospheric air from the vessels he employed.

Citizen Hallé has again offered the principal facts deduced from the experiments contained in the third part. The objection of Citizen Seguin against their result in general, that there is uniformly produced a kind of *mephités* in the intestinal canal, is, that, on the contrary, the predominance of azote in the large intestines, according to the experiments of Jurine, ought not to be attributed to the atmospheric air contained in the stomach and intestines losing a portion of oxygen, and the azotic gas becoming by that means more abundant.

The fourth part of this work exhibits a short view of the improvements medicine has received from pneumatic chemistry, which, in the report, is brought down to the present period.

The memoir of M. Gattoni, like the preceding, is intended to give a solution of the physiological problem proposed by the Medical Society, and contains the particulars of a variety of researches and experiments. The author, after relating the history of the nitro-aërial eudiometer, and shewing the incorrectness of that instrument, and its general insufficiency to ascertain the change of the air by the different kinds of inflammation, adopts the eudiometer of Volta, which he describes. The experiments made with this latter instrument, like those made with all the others, have only elucidated the different proportions of azote, oxygen, and carbonic acid gas variously modified, by different airs, or by the state of the patient on whom the experiments were tried, or by the different causes of disease.

EVE, the mother of all mankind; who, being deluded by the serpent, occasioned the fall, and all its dismal consequences. See ADAM.

EVERDING, a town of Upper Austria, seated on the

Danube, 12 miles W. of Linz. Long. 13. 46. E. Lat. 48. 19. N.

EVERFIELD, a town of Westphalia in the duchy of Berg, seated near the Wipper, 18 miles E. of Dusseldorf.

EVERSHOT, a town in Dorsetshire, with a market on Friday, 12 miles N.W. of Dorchester, and 129 W. by S. of London. Long. 2. 55. W. Lat. 50. 52. N.

EUGUBIO, an episcopal town of Italy, in the duchy of Urbino, 35 miles S. of Urbino, and 87 N. of Rome. Long. 13. 37. E. Lat. 43. 18. N.

EVIAN, a town of Savoy, in Chablais, resorted to in the summer for its mineral waters. It is seated on the S. side of the lake of Geneva, 22 miles N.E. of Geneva. Long. 6. 50. E. Lat. 46. 21. N.

EUMENES, the most worthy of Alexander's successors and generals; was safely delivered up by his own troops to his rival Antigonus, and by him put to death, 315 B. C.

EUMENES II. king of Pergamus, a valiant general, patron of learning, and founder of the famous library at Pergamus, on the model of that at Alexandria. He died 159 B. C. after a reign of 39 years.

EVOLI, an ancient town of Naples, in Principato Citereiore, 12 miles E. of Salerno. Long. 15. 16. E. Lat. 40. 46. N.

EVORA, a fortified city of Portugal, capital of Alentejo, with an archbishop's see, and a university. Some remains of the ancient Roman wall are visible, and the famous aqueduct built by Sertorius still conveys a noble stream of water to the city. Evora is seated in a country which, though a little unequal, is very pleasant, surrounded on all sides by mountains, and planted with large trees of divers sorts. It is 65 miles E. by S. of Lisbon. Long. 7. 30. W. Lat. 38. 28. N.

EVORAMONTE, a town of Portugal in Alentejo, situate on a rock, eight miles S.W. of Estremoz, and 15 N.E. of Evora.

EUPATORGIA, a town of Russia, in the government of Taurida, on the Black Sea, 68 miles S.W. of Precop. Long. 33. 14. E. Lat. 45. 40. N.

EUPHEMIA, a sea-port of Naples in Calabria Ulteriore, seated on a bay, 50 miles N.E. of Reggio. Long. 16. 32. E. Lat. 38. 44. N.

EURVILLE, a town of France, in the department of Upper Marne, five miles S.E. of Dizier.

EUTAM, a small island of the West-Indies, near the E. coast of Porto Rico. Long. 64. 41. W. Lat. 18. 18. N.

EUTIM, a town of Holstein, with a castle, where the bishop of Lubec resides. It is seven miles N. of Lubec.

EWELL, a town in Surrey, with a market on Thursday, seated on a rivulet which empties itself into the Thames, at Kingston. It is 10 miles N.N.E. of Dorking, and 13 S.S.E. of London. Long. 0. 15. W. Lat. 51. 26. N.

EXCHANGE, *BILLS OF* (*Encycl.*). On promissory notes, drafts, or orders, by 31 Geo. III. c. 25; 37 Geo. III. c. 90; and 41 Geo. III. c. 10, the following duties are payable, viz.

On bills and notes payable on demand.] For every piece of vellum, parchment, or paper, upon which any bill of exchange, draft, or order for the payment of money on demand, shall be written, &c. where the sum amounts to 40s. and does not exceed 5l. by 31 Geo. 3. c. 25, three-pence; 37 Geo. 3. one penny; 41 Geo. 3. c. 10, two-pence.—Total 6d.

Above 5l. 5s. and not exceeding 30l. by 31 Geo. 3. c. 25, six-pence; 37 Geo. 3. c. 90, two-pence; 41 Geo. 3. c. 10, four-pence.—Total 1s.

Above 30l. and not exceeding 50l. by 31 Geo. 3. c. 25, nine-pence; 37 Geo. 3. c. 90, three-pence; 41 Geo. 3. c. 10, six-pence.—Total 1s. 6d.

Above 50l. and not exceeding 100l. by 31 Geo. 3. c. 25, one shilling; 37 Geo. 3. c. 90, four-pence; 41 Geo. 3. c. 10, eight-pence.—Total 1s.

Above 100l. and not exceeding 200l. by 31 Geo. 3. c. 25, one shilling and six-pence; 37 Geo. 3. c. 90, six-pence; 41 Geo. 3. c. 10, one shilling.—Total 3s.

For every promissory, or other note, for payment of money to the bearer on demand, which may be re-issuable, after payment, at the place where the same was first issued, where the sum amounts to 40s. and does not exceed 5l. by 31 Geo. 3. c. 25, three-pence; 37 Geo. 3. c. 90, one penny; 41 Geo. 3. c. 10, two-pence.—Total 6d.

Above 5l. 5s. and not exceeding 30l. by 31 Geo. 3. c. 25, six-pence; 37 Geo. 3. c. 90, two-pence; 41 Geo. 3. c. 10, four-pence.—Total 1s.

Above 30l. and not exceeding 50l. by 31 Geo. 3. c. 25, nine-pence; 37 Geo. 3. c. 90, three-pence; 41 Geo. 3. c. 10, six-pence.—Total 1s. 6d.

Above 50l. and not exceeding 100l. 31 Geo. 3. c. 25, one shilling; 37 Geo. 3. c. 90, four-pence; 41 Geo. 3. c. 10, eight-pence.—Total 2s.

Above 100l. and not exceeding 200l. by 31 Geo. 3. c. 25, one shilling and six-pence; 37 Geo. 3. c. 90, six-pence; 41 Geo. 3. c. 10, one shilling.—Total 3s.

When these promissory notes shall be paid by the person by whom the same shall have been made or signed, and first issued, and at the place where the same were first issued, the person so paying the same, notwithstanding such payment may at any time afterwards, and so often as there shall be occasion after every such payment thereof, but not otherwise, again issue and negotiate such notes; and every such note is declared to be after payment, but not otherwise, issuable and negotiable. But if such notes shall be paid by any other than the person making or signing the same, or at any place other than the place of issuing, such note shall be construed to be vacated and satisfied, and shall be no longer negotiable but cancelled; and if any person shall again issue any such note after payment by any person other than the person making the same, or at any place other than the place of issuing, or if any person named in such note for payment thereof, shall after payment neglect or refuse to cancel the same, such person shall forfeit 20l. And if such note shall not be cancelled, then, and as often as it shall be again issued, there shall be due, answered, and paid the like duty as was first charged on such note, to be payable by and charged on the person who shall again issue and negotiate such note, f. 7.

For any promissory or other note, payable to the bearer on demand, which may be re-issued, after payment at the same, or any other place than where first issued, where the sum shall amount to 40s. and not exceed 5l. by 31 Geo. 3. c. 25, six-pence; 37 Geo. 3. c. 90, two-pence; 41 Geo. 3. c. 10, four-pence.—Total 1s.

Above 5l. 5s. and not exceeding 30l. by 31 Geo. 3. c. 25, one shilling; 37 Geo. 3. c. 90, four-pence; 41 Geo. 3. c. 10, eight-pence.—Total 2s.

[It is declared that these notes may, as often as occasion shall require, be again issued by the person making the same, notwithstanding such notes have been paid by the person making the same, or any other person in pursuance of any appointment for the payment thereof.]

Bills and notes payable after date.] For every bill of exchange, draft, or order, payable otherwise than on demand, or any promissory or other note payable otherwise than to the bearer on demand, where the sum shall amount to 40s. and not exceed 30l. by 31 Geo. 3. c. 25, six-pence; 37 Geo. 3. c. 90, two-pence; 41 Geo. 3. c. 10, four-pence.—Total 1s.

Above 30l. and not exceeding 50l. by 31 Geo. 3. c. 25, nine-pence; 37 Geo. 3. c. 90, three-pence; 41 Geo. 3. c. 10, six-pence.—Total 1s. 6d.

Above 50l. and not exceeding 100l. by 31 Geo. 3. c. 25,

one shilling; 37 Geo. 3, c. 90, four-pence; 41 Geo. 3, c. 10, eight-pence.—Total 2s.

Above 100l. and not exceeding 200l. by 31 Geo. 3, c. 25, one shilling and six-pence; 37 Geo. 3, c. 90, six-pence; 41 Geo. 3, c. 10, one shilling.—Total 3s.

Bills and notes exceeding 200l. value. And for every bill of exchange, promissory, or other note, draft, or order, payable on demand or otherwise, where the sum shall exceed 200l. there shall be charged by 31 Geo. 3, c. 25, two shillings; 37 Geo. 3, c. 90, eight-pence; 41 Geo. 3, c. 10, one shilling and four-pence.—Total 4s.

Which duties shall be paid by the person making or signing such bills, &c.

Foreign bills of exchange. Drawn in sets, according to the custom of merchants, where the sum shall not exceed 100l. shall be charged by 31 Geo. 3, c. 25, six-pence; by 37 Geo. 3, c. 90, three-pence; 41 Geo. 3, c. 10, four-pence.—Total 1s. 1d. —Exceeding 100l. and not 200l. 31 Geo. 3, c. 25, nine-pence; 37 Geo. 3, c. 90, three-pence; 41 Geo. 3, c. 10, six-pence.—Total 1s. 6d. —And exceeding 200l. by 31 Geo. 3, c. 25, one shilling; 37 Geo. 3, c. 90, four-pence; 41 Geo. 3, c. 10, eight-pence.—Total 2s. —And every bill of each set so drawn is said to be chargeable with the duty.

N. B. The time limited in the act 41 Geo. 3, for the commencement of the new duties, is from and after April 5, 1801.

The exemptions from the foregoing duties, are these:

1. Drafts or orders, payable to bearer on demand, bearing date on or before the day on which the same shall be issued, and at the place from which the same shall be drawn and issued, and drawn upon any banker, or person acting as a banker and residing and transacting business as a banker, within ten miles of the place where such draft or order shall be actually drawn and issued.

2. All notes and bills whatever issued by the bank of England, upon condition of their paying into the exchequer the annual sum of 12,000l. half yearly, on Oct. 10 and April 5.

New regulations in 31 Geo. 3, c. 25.

If any bill, &c. shall be written on paper not stamped, or stamped with a stamp of lower value than directed; then there shall be due and paid the full duty hereby chargeable; which shall be payable by and charged upon all persons who shall draw or make, and utter and negotiate such bill, &c. f. 6. And all persons who shall write or sign, or cause to be written or signed, or who shall accept or pay, or cause to be accepted or paid, any bill, &c. without being first stamped with a proper stamp, or upon which there shall not be some stamp resembling the same, shall forfeit 20l. f. 10.

Every promissory or other note, payable to the bearer on demand, which shall be issued after payment under this act, shall notwithstanding be payable to the person holding the same; and such person may maintain an action thereupon. f. 9.

The 18th section declares, that no bill, &c. shall be available in law or equity, unless stamped with the lawful stamp; and that it shall not be lawful for the commissioners to stamp any paper, &c. after any bill, &c. shall be written thereon, under any pretence whatever.

But it shall be lawful for any person who shall be the holder of any bill, note, draft, or order, made after July 20, 1797, which shall be stamped with a stamp of a different denomination than required, if the same shall be of equal or superior value to the stamp required, to produce the same within the times herein-after mentioned, to the head office or such officer as the commissioners shall appoint; and the commissioners may direct the proper officer, upon payment of the duty, and such penalty as is after mentioned, over and above the duty, to stamp such bill, note, draft, or order, with the proper stamp, and to

give a receipt for the duty and penalty, so paid, on the back of such bill, note, draft, or order.

If any such bill, note, draft, or order, shall be produced before the same shall be payable, the same shall be stamped on payment of the said duty, and the penalty of 40s.; but if the same shall be payable before the production thereof to the commissioners, then the same shall not be stamped, unless on payment of the duty and 10l. for the penalty.

The method of recovering the penalties is the same as under the receipt tax—which fee under the head RECEIPTS in this SUPPLEMENT.

Note also, that by 41 Geo. 3, c. 10, no note re-issuable on March 24, 1801, shall be so after June 5, 1801, until properly stamped with the new duty.

EXCOECARIA (*Encycl.*). Of the Excoecaria Agallocha, Professor Willdenow, of Berlin, has given the following account in a late publication.

The agallochum, which is known by the name of aloë-wood, or the aromatic aloë, is one of the most valuable spices imported from the East, and has been in high estimation, even in the earliest ages. According to the different species of the plant, it is called *lignum aloës*, *agallochi xeri*, *agallochi*, and *calam bæ*, all of which differ remarkably in their sensible properties. It is, however, very difficult to ascertain the botanical character of these various species.

The aromatic wood of aloë is properly a resin, which has pervaded the pores of the tree. The genuine sort of this resinous wood is as precious as gold, and is used only by the great and affluent in the East Indies, China, and Japan, as an agreeable perfume, with which they fumigate houses: hence it is but rarely imported into Europe. It is black, and variegated with grey veins, swims on water, and if strongly rubbed on glass, leaves behind resinous particles, which neither water, saliva, expressed oils, nor an alkaline lye, but spirit of wine only will dissolve and remove. Its odour is very grateful.

This substance has, in former times, been much used as a medicine, not only in biliary complaints, diseases of the liver and stomach, and dysentery, but likewise as a remedy for the maw-worm; but at present it is entirely neglected—a revolution to which several of the ancient remedies have been subject, and which is likely to take place with many of the modern.

Father DE LOUREIRO assures us, that he discovered, in the province of Cochinchina, the tree which affords the true aloë. This aromatic wood is found in resinous masses, only in old, half-decayed, hollow trees. According to this writer, the tree belongs, in the system of LINNÆUS, to the first division of the tenth class, the Decandria Monogynia: he called it *Aloëxylum Agallochum*. It grows on the highest mountains of Cochinchina, on the banks of the river Lav, which flows through the whole of that province. Loureiro had no opportunity of seeing the blossoms on the tree; he could only once obtain them dried, and transmitted by a friend, so that the parts of fructification were much bruised and lacerated on a long journey, and he could with difficulty give the following description:—

ALOEXYLMUM AGALLOCHUM. Differ. spec. Aloë. *foliis lanceolatis*, *altissimis: pedunculis polyfloris*, *terminalibus*.

Hab. *Arbor magna: truncus et ramis erectis, altissimis: cortice cannabino, fusco, glabro, nec crasso.*

Folia lanceolata, obli polyes longa, integerrima, plana, glabra, subcoriacea, alterna, petiolata. Flores terminalis, pedunculis polyfloris.

Ufus. *Ligni hujus suffumens inter omnia maximè æstimatur apud nationes Orientales. Ex arboris cortice fit vulgaris charta, in quâ Cochinchinenses scribunt, sicut in Japonia fit ex cortice Mori.*

Virtus medica. *Excitans, corroborans, cephalica, cardiaca.*

Suffitus valet contra vertiginem et paralyfism. Pulvis cohibet vomitum et fluxus ventris, præcipue Lientricos, quod non proprie astringendo, fed corroborando agit.

This tree is not of a poisonous nature, and yields no milky sap when perforated. With respect to the *genuine* wood of aloe, Loureiro maintains that the various species differ remarkably, both in colour and flavour. By some botanists, this aromatic wood has been confounded with the *Lignum Aquilæ*, which is likewise esteemed for its agreeable odour, and like the *Agallochum verum*, Calambac, and Garo de Malacca, affords different species of perfume. KÆMPFER and LAMARCK have given a particular description of the genuine aromatic aloe. CAVANILLES, an eminent botanical writer, calls the plant that produces this valuable drug *Aquilaria ovata*.

In Plate 26 we have given a representation of this plant: *a* is a branch of the natural size, with the catkins just opened: *b* a catkin in full blossom.

EXCULPATION LETTERS OF, in Scots law, a writ or summons issued by authority of the court of judicatory, at the instance of a pannel, for citing witnesses to prove his defences, or his objections to any of the jury or witnesses cited against him.

EXECUTOR, in Scots law, signifies either the person entitled to succeed to the moveable estate of one deceased, or who by law or special appointment is entrusted with the administration of it.

EXECUTRY, in Scots law, is the moveable estate falling to the executor. Under executry, or moveables, is comprehended every thing that moves itself, or can be moved; such as corn, cattle, furniture, ready money, &c.

EXERCITOR, in Scots law, he who employs a ship in trade, whether he be owner, or only freights her from the owner.

EXETER, a town of N. Carolina, on the N.E. branch of Cape Fear River, 30 miles N. of Wilmington.

EXETER, a town of New Hampshire, on Exeter River, with a good harbour, 15 miles S.W. of Portsmouth.

EXIDEUIL, a town of France, in the department of Dordogne, 20 miles N.E. of Périgueux, and 32 S. of Limoges. Long. o. 54. E. Lat. 45. 24. N.

EXILLES, a strong fort of France, in the department of the Upper Alps. It was taken by the Duke of Savoy in 1708, but restored by the treaty of Utrecht. It is an important passage, six miles W. of Suza, and 40 N.E. of Embrun.

EXMOOR, a forest in Somersetshire, in the N.W. corner of that county, extending thence into Devonshire.

EXMOUTH, a village in Devonshire, on the E. side of the bay which forms the mouth of the river Ex, 10 miles S. by E. of Exeter. It is much frequented for the benefit of sea-bathing.

EXPANSION (*Encycl.*). The following paper on the expansion of wood by heat, by Dr. Rittenhouse, appears in the Transactions of the American Philosophical Society.

"In the present state of experimental philosophy," says the doctor, "it is well known that bodies in general enlarge their dimensions, or expand, on being heated, and contract in cooling. From some experiments heretofore made, wood has been thought to make an exception to the general rule, and this opinion has so prevailed that many curious persons have applied wooden pendulum rods to their time-pieces, to prevent the variation in their rate of going, arising from the expansion and contracting of a metal rod. From my own observations, however, as well as those of some of my friends, the wooden pendulum rod does not appear to answer the expectations formed on it. I had in my possession for several years an excellent time-piece, made for this society by an ingenious workman and worthy member of the society. The result of my constant attention to this clock was, that though its regular variations with heat and cold were probably much less than

those of metal pendulums, it nevertheless went always faster in winter than in summer, and was liable to very sudden and considerable variations; arising, no doubt, from the combined effects of heat and cold, moisture and dryness. This determined me to make some careful experiments with a pyrometer capable of receiving a piece of wood of the length of a second pendulum. Several years ago, I made some experiments of this kind, perfectly corresponding with those I have lately made, and which I now communicate to the society.

"I took a straight-grained piece of white hickory, green, for I could not procure any seasoned, its length 39 inches, and about $\frac{3}{4}$ of an inch square. This I placed in my pyrometer, and kept it fully extended by a weight fastened to a string, going over a pulley. To the pyrometer I applied the tube and glasses of a good compounded microscope, and a micrometer, the value of the smaller divisions whereof I found to be nearly .00053 parts of an inch, each.

"The rod of wood being placed in the pyrometer, I poured sand all around it, heated to about 250 of Fahrenheit, which degree of heat I found the wood would bear without scorching. On pouring in the hot sand, the rod expanded very much, but soon began to contract, even before the sand was sensibly cooled, which I suppose arose from the hot sand extracting the moisture of the wood. It continued to contract as the whole grew cool, so that when the rod had acquired its first temperature it was near 30. of the above divisions shorter than at first. I repeated the operation a second and third time, and had then reason to conclude, that the wood was nearly as dry as it would become by lying long in a dry air. I now let it cool to the temperature of the atmosphere, which was 75° and heating the sand to 200 only, I poured it around the rod. In a few minutes it expanded 16 divisions. In half an hour the sand had cooled to 125, and the rod had contracted 11 divisions. In an hour more the sand was 80, and the rod shortened full 4 divisions more, being nearly equal to its length when the sand was first applied. On the whole I conclude that very dry wood expands with heat pretty regularly, though certainly in a much less degree than any of the metals or even glass.

"The rod above mentioned having been kept in a dry place for twelve months, I again tried it with the pyrometer, having fixed near one end of it a small graduated scale of ivory, 360 divisions whereof were equal to one inch. This scale was viewed with the microscope, furnished with a cross hair, and I thought this method preferable to the screw micrometer used before.

"The rod was placed in the pyrometer when the temperature of the air was about 60°. On pouring sand around it, heated a little higher than boiling water perhaps, it immediately expanded $\frac{1}{2}$ a division, but in less than a minute it began to contract, and continued to do so for an hour, when I drew off the sand. It was now full 10 divisions shorter than at first, so that it had imbibed a great deal of moisture from the air, which it again parted with to the heated sand. Three hours afterwards, when the rod was cool, I again poured the sand on it, heated as before. It now continued to expand for about three minutes, when its length was increased $3\frac{1}{2}$ divisions, it then began to contract, and became full 3 divisions shorter than when the sand was poured on it. I cauled the sand to run off once more, and let the rod cool. Then heating the sand 250° by a thermometer, I poured it on the rod, and in a few minutes it expanded $3\frac{1}{2}$ divisions, it then began to contract slowly, and in 15 minutes it became $\frac{2}{3}$ of a division shorter than at first. On the whole, I conclude that the expansion of wood, in its length, will be irregular, corresponding partly to the warmth, and partly to the moisture of the atmosphere."

EYE, a river, which rises in the N. W. part of Berwickshire, and falls into the British Ocean, at Eyemouth.

EYESDALE, a small island on the coast of Argyleshire, to the S. E. of Mull. It is noted for its slate quarries.

EYMOUTIERS, a town of France, in the department of Upper Vienne, containing about 2000 inhabitants, with a considerable trade in skins, leather, and rags. It is seated on the

Vienne, 20 miles N. of Limoges. Long. 1. 10. E. Lat. 46. 10. N.

EYMOUTIERS, a town of France, in the department of Dordogne, 15 miles S. of Perigueux.

EYNDHOVEN, a town of Dutch Brabant, in the district of Bois-le-Duc, at the confluence of the Eyns and Dommel, 13 miles S. E. of Bois-le-Duc. Long. 5. 26. E. Lat. 51. 31. N.

F.

F A C

F AABORG, a sea-port of Denmark, on the south coast of the island of Funen, 17 miles S. of Odensee. Long. 10. 16. E. Lat. 55. 12. N.

FABRIANO, a town of Italy, in the marquisate of Ancona, famous for its excellent paper. It is 25 miles N. E. of Foligno. Long. 12. 32. E. Lat. 43. 10. N.

FACE-ACH, a name popularly given to any slight rheumatic affection of the face. The term, however, more properly belongs to a most formidable chronic disorder of that part, which, not being understood by physicians, has hitherto gone by the quaint and untechnical appellation of DOLOR FACIÆ.

This dreadful disease, which is commonly styled the *Dolor Faciæ* of Fothergill*, on account of its being supposed to have been first mentioned by that practitioner, was before known, in the year 1756, to Mr. Andre, surgeon at Paris, who accurately described it under the name of *tic*, and explained it with several observations. Mr. Siebold, however, traced the history of this disorder further back, finding that, in 1724, it had been treated by John Hartmann Degener, practitioner at Nimmegen, whose excellent observation and description of that affection is communicated in the first volume of *Acta Naturæ Curiosæ*, (*de dolore quodam perrara acerbique maxillæ sinistræ partes occupante et per paroxysmos recurrente*, p. 347). This practitioner even supposed, that Lawrence Bauch, physician at Schweinfurth in Franconia, president and founder of the Societas Naturæ Curiosorum, died of this disorder in the year 1665, according to the annals of that society. The patient felt for four years a very excruciating pain in the right maxilla, sometimes growing less, and then ceasing; but, at last, it increased to such a degree, that he became unable to speak or to swallow, and, notwithstanding all possible remedies, died emaciated, and with a palsy on the left side. There existed also, Observations on this disease by Dr. Daniel Ludwig, in the year 1673.—*Misc. Nat. Cur. Dec. I. Ann. III. Observ. 252*, *de dolore superciliaris acerbissimo*.

The Dolor Faciæ may be called analogically (otalgy, odontalgia, &c.) *protopalgy*, as it undoubtedly belongs to the topical pains without fever; and this name seems, besides, to be congruous with respect to the seat as well as to the origin and kind of pain. The seat of the disease has been thought to originate in the teeth, but even drawing of them proved to be of no effect. It is observed by Dr. Fothergill, that the disease generally appears about the fortieth or fiftieth year of age, a period in which people are not much subject to tooth-ach; and though several patients suffered tooth-ach at the

F A C

same time, yet others were quite exempt. The *antrum Highmorianum* is equally assigned as the seat of the disease, but without any probability, as it seems impossible a pain so severe, and lasting for so long a time, should take place there, without producing some change, inflammation, and suppuration, which never was the case in all the instances of that painful affection, according to what we find recorded in the annals of medicine: teeth were drawn out, and an opening made into the *antrum*, without ever perceiving any matter to issue thence. The pain generally extends itself to the jaws, a circumstance which is to be ascribed to the distribution of nerves. The disease, luckily, occurs so seldom, that even physicians of the most extensive practice never had an opportunity of observing it: we find it, however, mentioned by practitioners of all nations, except the Italians. Dr. Fothergill met with sixteen instances of it; Dr. Thilenius, a German physician, saw it but twice during a most extensive practice of twenty years; Dr. Aepi, a Swiss physician, only once in twenty-seven years. The following exhibits the literature of different nations on the above disease.

Fothergill observed, that this disorder mostly attacks women; but Degener and others saw it in men. Mr. Siebold met with three instances in the female sex, and one in a man; it seems, however, to occur more frequently in women than in men, and the proportion is about five to four. It is remarkable, that the subjects of the disease in England were mostly women, in the proportion of 1 to 14; and in Germany mostly men, in the proportion of 21 to 13. On reviewing the cases mentioned by different authors, we observe that they were for the most part confined to the period of age between the thirtieth and eightieth year; and instances of the disorder being met with at an earlier period of life have but rarely occurred. The German translator of Dr. Fothergill's works relates a case of a young lady, nineteen years of age; and also Dr. Leidenroft a similar instance (*Dissert. supra citat.*). Dr. Rahn, Prof. Weidmann of Mentz, and Prof. Siebold of Wurzburg, are the only persons who have observed this disorder in pregnant women. The patient of Prof. Weidmann was attacked by the pain a month before her delivery: evacuations were fruitlessly employed; but she was cured by opium and bark. Dr. Siebold's case is very remarkable, on account of the pain ceasing entirely during pregnancy, a circumstance that seems to prove the great power which the body enjoys in this state, of resisting several diseases, a remark already made by Hippocrates (*de internis affectionibus*, cap. 53, ed. chart. t. viii.

* Doloris Faciæ, morbi rarioris atque atrocis observationibus illustrati, adumbratio Diatribæ I. qua exercitationes clinicas in nosocomio juliano habendas indicit G. Ch. Siebold, Dr. Med. Prof. Wirceburgi, 1795, pp. 22, in 4to.—Diatribæ II. qua pro capessendo in illustri inclyta et ornatissima facultate medica loco et dignitate ad orationem die xxix Jul. 1797, publice celebrandam invit. pp. 23, in 4to. Translated in the Med. and Phys. Journ. No. XXX.

p. 677), who tells us that a dolor ischiadicus disappeared during the period of pregnancy, which, however, recurred twenty days after the delivery. Dr. Sauter saw this painful affection disappear during a putrid fever, and Dr. Selle in an intermittent fever; in both which cases it returned after the fevers were cured. It seems not improbable, but that this disorder may be endemic, and even epidemic; at least the disease has not been more frequently observed than at Clausthal, the capital of the Hercynian mountains; and in the mountainous country of Salzbourg, it is not at all rare. Mr. Andre remarks, that in a very short time he met with eight or ten cases of this disorder, whereas he had not a single one afterwards during a period of twenty-seven years.

This affection seems not to be peculiar to a particular temper and habit of body, but attacks people of very different constitutions suddenly and unexpectedly: its duration is extremely long, as it may last for many years without doing any evident harm to the whole constitution, or without terminating fatally in an immediate manner. A woman suffered this painful affection from her nineteenth year to her eightieth, and got rid of it but shortly before she died. In other cases, however, the disorder emaciates and destroys the body, particularly for want of rest: the diseased side of the face is frequently disfigured, and persons subject to this affection receive, as it were, a double profile, of which Prof. Baldinger relates a curious instance in his Medical Journal, volume ii, No. 7.

Although many symptoms of this disorder are of the spasmodic kind, yet we have more reason to think it to belong to the class of convulsive disorders, and it is therefore erroneously called *trismus dolorificus*, after Sauvages and Puzos, because the vehement contortions do not occur in every patient, and may, moreover, be rather considered as *cyanina nutura medicatrix*, and efforts by which the patients endeavour to relieve themselves from pain, for which purpose they likewise rub the part with much vehemence. A difficulty of speech and of swallowing are observed in some cases, probably from the distortions of the muscular fibres that are subservient to this purpose. A considerable salivation came on in another instance, where the patient became almost hectic; but Mr. Siebold attended a patient whose falival excretion was entirely suppressed; another subject of that disorder had a very much swollen *glandula Warthoni*, from which a fetid and purulent matter issued. The eyes remain sometimes dry, and it is not always that the pain forces out tears; sometimes they become red and humid. In some patients a redness and heat of the affected part precedes the paroxysm of pain, of which phenomenon a curious instance is related by Dr. Rahn, where the heat was so intense that it could be felt at some distance. Other symptoms frequently to be remarked in patients of this kind are, an intumescence of the belly, a torpor of the intestinal canal, and an obstinate costiveness, which are probably owing to a spasm of the *nervus sympatheticus magnus*, that is intimately connected by anastomosis with the fifth pair; an opinion which agrees also somewhat with analogy, as we do not rarely observe, that if the cheeks, or the cheek-bones, are any way affected, the liver is also diseased: those symptoms ought, therefore, to be rather considered as merely secondary, and arising *per consensum*, than as the causa primaria of the disease. It has been observed in one case by Dr. Lentin, that when the belly began to swell, the pain soon after disappeared; and in another case it was greatly diminished by it, which symptom seems to prove that the morbid matter is deposited on the intestines: it deserves, however, to be ascertained by further observations. It is remarkable, that in a case of Dr. Siebold, the patient had a particular relish for sweet things, which that gentleman is inclined to ascribe to a

depravation of taste, occasioned by the affection of the neighbouring nerves, or to an obstruction of the liver, in which this symptom sometimes occurs. The pulse was often full, slow, and soft, during the paroxysm, and at other times it decreased ten beats at every return of the pain.

The seat of the pain has been observed,

1. In some single part of the face, viz. at the inner canthus of the eye, Fothergill; in the orbita, the same; at the supercilia of the right eye, Puzos; in the jaw-bone, Fothergill; in the joint of the jaws, Selle, Puzos; in the maxilla inferior, at the passage of the *nervus infraorbitalis*, Lentin; in the ossa temporaria, Fothergill; in the *nervus infraorbitalis*, Albinus and Van Wy; in the *ala nasi*, Vogler, Thourret, at the margin of the tongue, Lentin.

2. In one half of the face, Fothergill.

3. In both cheeks, Puzos.

4. In both sides of the maxilla inferior, at the exit of the nerve.

5. In the whole head and face, Lentin.

6. In one foot, Lentin. (See Med. and Phys. Journal, vol. iii. 575.)

The head and face are particularly exposed to this painful affection, on account of the quantity of nervous fibres that every-where spread over the surface of the head. The pain essentially differs from any other that occurs in the various parts of the human body, though it may, in some measure, be compared with the *dolor ischiadicus* of Cotunni. Dr. Lentin derives its origin from the *medulla oblongata*; and Prof. Siebold likewise thinks it may originate in a part remote from the affected place, in the *ganglion Gasseri*; others have derived it from the bones; but we still want anatomical observations for ascertaining the proper source of the pain.

Remote causes.] The *causae praedisponeutes* of the disorder appear to be, 1. Violent blows and contusions of the above parts, Andre. 2. Cicatrices, Lentin. 3. Preceding tooth-ach. 4. Too great tenderness of the skin; but the disorder occurred in persons whose skin was by no means to be called tender or soft. 5. Congestions towards the head.

Internal causes.] 1. Cancerous acrimony. Dr. Fothergill first proposed this opinion, whence it has been called by some authors, the *cancerous rheumatism*. The cancerous nature of the disease seems to be confirmed by the following arguments: 1. There is no other cause to be discovered, but that it is owing to a cancerous poison. 2. It most frequently occurs in women, who are particularly disposed to cancers. It generally appeared at the period of the ceasing menstruation, or when they were past the time of menstruation, where a particular tendency to cancer takes place. 4. The kind is exceedingly similar to that occasioned by a cancer. 5. Both disorders have much analogy in their preceding symptoms. 6. Four women suffering this affection, had the *scirrhus mammarii* previously. 7. The effect of hemlock in this disease, which is likewise much praised in cancers.

Adverse arguments.] 1. The disease is not at all uncommon in men, where cancerous acrimony could not be traced, as well as in many women. 2. Menstruation did not always cease in some patients, but they became even pregnant during the disease. 3. The cancerous poison easily attacks glandular parts, but we seldom find them altered, indurated, or painful in the neighbourhood of the pain. 4. There is no instance of the Dolor Faciei having terminated in a cancer of the lips or of the cheek. If it did, however, arise from a cancerous acrimony, it should be more frequently observed in men than women, because the *cancer labiorum* is oftener observed in the male sex. 5. The parts disposed to cancer have been frequently irritated by the persons who had the Dolor Faciei, without ever producing such an affection. 6. It is

not probable that the cancerous acrimony should remain so long at a place so sensible, without manifesting itself in a general way.

These arguments are indeed of some weight, to make us believe that a cancerous poison is by no means the only cause of that affection, nay, that it is not even to be considered as a chief cause of it.

Arthritic matter. Almost all the authors who have treated on this subject, agree in assigning this as the proximate cause of that disorder, but particularly Dr. Leidenfrost. Dr. Dege-ner is likewise of this opinion, having observed at the affected place a tumor similar to that in the joints of gouty people. Dr. Seibold saw, in a patient suffering the most violent pains at the *supercilia*, a node perfectly like that of arthritic limbs; and Dr. Ludwig fairly tells us, that the patients suffering this disorder became gouty soon after. The disease seems to have an arthritic origin in the cases related by Dr. Bochner and Lavagan, who found the pain disappear when the usual arthritic paroxysms returned.

3. *Exanthematic acrimony.* Exanthemata have been observed in this disease, either in the face itself or in some other part of the body. Mr. Andre observed milium eruptions in the face, upon the disappearance of which the pain began to cease; but when they broke out again, the pain recurred with the former violence. Bonnard and Legavan relate instances of herpetic eruptions on the arm having preceded the disorder; and the German translator of Dr. Fothergill's works saw it appear after a retrograde itch: the pain discontinued when the itch broke out again, but as soon as it was removed by proper remedies, the pain immediately returned; and the disease lasted in this way from the nineteenth year of age to the twenty-seventh.

4. *Scrophulous acrimony.* Menouret and Selle (loc. cit.) assign this as a cause of the disease in two instances.

5. *Catarrhus acrimony.* Vogler and Pujol, loc. cit.

6. *Rheumatic matter.* It is not improbable that this is a most frequent cause of that painful affection, which we find likewise confirmed by the authority of experience and obser-vation.

7. *Veneral poison.* M. Seibold is not inclined to admit this as a cause of the above disease, because the venereal pain is always feverish in the night than in the day, without inter-missions, and seems to be more seated in the bones than in the muscular and nervous parts. We have, besides, no obser-vation of the venereal poison being assigned as the cause of that pain, if we except Mr. Watson. (*Journal de Médecine*, 1793, month of March.) It has been, however, observed, that the disease was successfully treated with mercurials; but this can by no means serve as an argument for the venereal nature of the disorder.

8. *Preceding ferrous purities suppressed.* Dr. Lentin relates a case in which a purulent salivation preceded the pain, by the appearance of which, the paroxysm of the pain became less vehement and shorter: in another case the pain succeeded a running of the ears: and Dr. Thilenius saw a patient who had a kind of gonorrhoea previous to the pain, which began to run again as soon as the pain had ceased.

Van Swieten (*Commentar. in Aphorism. Boerhaav. §. 757*) and Davidson (*loc. citat.*) have observed a pain in the face, similar to an ague, which, however, essentially differs, ac-cording to Dr. Fothergill, from the disorder we are speaking of. The patient of Van Swieten had a very severe hemicra-nia, lasting every day for eight hours, which, after this time, abated by degrees. At the first attack the pain appeared in the place where the branch of the fifth pair issues from the foramen supraorbitale: in another case a topical febrile pulse was remarked at the affected place; the disease was cured by

the bark. The typical character of this pain, and the termina-tion of its paroxysm, with a strong perspiration, sufficiently distinguish it from the true Dolor Faciei.

Four cases of this inexplicable malady are related in vol. ii. of the Edinburgh Practice of Physic, Surgery, and Midwifery.

FAHLUN, a town of Sweden, capital of Dalecarlia, situate in the midst of rocks and hills, between the lakes of Run and Warpen. It contains two churches, and (including the miners) 7000 inhabitants. The copper-mine, which gives existence and celebrity to the town, is on its east side. It is 30 miles N.W. of Hedemora. Long. 16. 42. E. Lat. 60. 34. N.

FAIRFIELD, a town of Connecticut, seated near the sea, 100 miles S.W. of Boston. Long. 73. 30. W. Lat. 41. 12. N.

FAIR ISLE, an island of the Northern Ocean, between Shetland and Orkney, from both which its high towering rocks are visible. On the E. side the Duke of Medina Sida-nia, admiral of the Spanish armada, was wrecked in 1588.

FAISANS, an island in the river Bidassoa, which separates France from Spain. It is also called the Island of Confer-ence, because Lewis XIV. and Philip IV. here swore to ob-serve the peace of the Pyrenées, in 1660, after 24 con-ferences between their ministers. Here also the hostages of France and Spain are received and delivered, it being con-sidered as a neutral place. It is situate between Andaye and Fontarabia. Long. 1. 46. W. Lat. 43. 20. N.

FAKENHAM, a town in Norfolk, with a market on Thursday; situate on a hill, 20 miles N.W. of Norwich, and 110 N.E. of London. Long. 0. 58. E. Lat. 52. 53. N.

FALAISE, a town of France, in the department of Cal-vados, with a castle, and one of the finest towers in France. It is remarkable for being the birth-place of William the Con-queror. It has a good trade in serges, linen, and lace; and its fair, which begins on August 16, is the most famous in France, next to that of Beaucourt. It is seated on the river Anté, 20 miles S.E. of Caen, and 115 W. of Paris. Long. 0. 2. W. Lat. 48. 53. N.

FALKENAU, a town of Bohemia, which has manufac-tures of alum, sulphur, and vitriol; seated on the Eger, 12 miles N. of Egra, and 66 W. of Prague. Long. 12. 38. E. Lat. 50. 21. N.

FALKENBERG, a sea-port of Sweden, on the Baltic, 17 miles N.W. of Helmsfadt. Long. 12. 50. E. Lat. 56. 52. N.

FALKENBURG, a strong town of Germany, in the new marche of Brandenburg, seated on the Traje, 60 miles E. of Stetin. Long. 15. 58. E. Lat. 53. 35. N.

FALKINGHAM, a town in Lincolnshire, with a market on Thursday, 18 miles W. by S. of Boston, and 104 N. of London. Long. 0. 20. W. Lat. 52. 48. N.

FALMOUTH, a town of Virginia, on the river Rappahan-noc. Long. 77. 32. W. Lat. 38. 21. N.

FALMOUTH, a sea-port in the state of Massachusetts, 50 miles S.S.E. of Boston. Long. 70. 32. W. Lat. 41. 31. N.

FALMOUTH, a town of the island of Jamaica, on the N. coast. Long. 77. 32. W. Lat. 18. 31. N.

FALSTER, a little island of Denmark, near the entrance of the Baltic, between the islands of Zealand, Laland, and Mona. Nikoping is the capital.

FALSTERBO, a sea-port of Sweden, in Schonen, chiefly known for a lighthouse and its herring fishery, 22 miles S.S.W. of Lund. Long. 12. 48. E. Lat. 55. 22. N.

FAMAGUSTA, a town in the island of Cyprus, with a Greek bishop's see, and a harbour, defended by two forts. It was taken by the Turks, in 1570, after a siege of six months, when they slayed the Venetian governor alive, and murdered the inhabitants, though they surrendered on honourable terms.

It is 62 miles N. of Nicofia. Long. 35. 55. E. Lat. 35. 10. N.

FAMARS, a town of France, in the department of the North, near which the French were defeated by the allies, April 21, 1793. It is three miles S. of Valenciennes.

FAMINE, PORT, a fortress, on the N.E. coast of the straits of Magellan. Here a Spanish garrison perished for want; since which it has been neglected. Long. 70. 20. W. Lat. 55. 44. S.

FANANO, a town of Italy, in the Modenese, 25 miles S. of Modena. Long. 11. 18. E. Lat. 44. 10. N.

FANJEAUX, a town of France, in the department of Aude, 14 miles W. of Carcassonne. Long. 1. 57. E. Lat. 43. 11. N.

FANO, a town of Italy, in the duchy of Urbino, with a bishop's see. Here are an ancient triumphal arch, handsome churches, and fine palaces. It is seated on the gulf of Venice, eight miles S.E. of Pesaro. Long. 13. 5. E. Lat. 43. 46. N.

FANTIN, a kingdom on the Gold Coast of Guinea, where the English and Dutch have forts. Its palm-wine is much better and stronger than that in other parts of the coast. The principal village has the same name.

FAREHAM, a town in Hampshire, with a market on Wednesday, 12 miles E. of Southampton, and 74 W. by S. of London. Long. 1. 6. W. Lat. 50. 53. N.

FAREWELL, CAPE, a promontory of the island of New Zealand. Long. 172. 41. E. Lat. 40. 37. S.

FARGEAU, St. an ancient town of France, in the department of Yonne, with a castle, 10 miles S.E. of Briare, and 82. S. of Paris. Long. 3. 8. E. Lat. 47. 40. N.

FARIM, a country of Africa, to the S. of the river Gambia. It has a town of the same name. Long. 13. 50. W. Lat. 14. 10. N.

FARM (*Encycl.*). At the conclusion of that article we pointed out as an instance of what an *ornamental farm* should be, that belonging to Mrs. Southcote, near Weybridge in Surrey, called Woburn Farm. It may not be amiss to describe this place, which contains 150 acres. Of these near 35 are adorned to the highest degree; of the rest, about two-thirds are in pasture, and the remainder is in tillage. The decorations are, however, communicated to every part: for they are disposed along the sides of a walk, which, with its appendages, forms a broad belt round the grazing-grounds; and is continued, though on a more contracted scale, through the arable. This walk is properly garden; all within it is farm; the whole lies on two sides of a hill, and on a flat at the foot of it: the flat is divided into corn-fields; the pastures occupy the hill; they are surrounded by the walk, and crossed by a communication carried along the brow, which is also richly dressed, and which divides them into two lawns, each completely encompassed with garden.

These are in themselves delightful; the ground in both lies beautifully; they are diversified with clumps and single trees; and the buildings in the walk seem to belong to them. On the top of the hill is a large octagon structure; and, not far from it, the ruin of a chapel. To one of the lawns the ruin appears, on the brow of a gentle ascent, backed and grouped with wood; from the other is seen the octagon, upon the edge of a steep fall, and by the side of a pretty grove, which hangs down the declivity. This lawn is further embellished by a neat Gothic building; the former by the house, and the lodge at the entrance; and in both, other objects of less consequence, little seats, alcoves, and bridges, continually occur.

The buildings are not, however, the only ornaments of the walk; it is shut out from the country, for a considerable length of the way, by a thick and lofty hedge-row, which is enriched with woodbine, jessamine, and every odoriferous plant whose tendrils will entwine with the thicket. A path, gene-

rally of sand or gravel, is conducted in a waving line, sometimes close under the hedge, sometimes at a little distance from it; and the turf on either hand is diversified with little groups of shrubs, of firs, or the smallest trees, and often with beds of flowers: these are rather too profusely sown, and hurt the eye by their littleness; but then they replenish the air with their perfumes, and every gale is full of fragrant. In some parts, however, the decoration is more chaste; and the walk is carried between larger clumps of evergreens, thickets of deciduous shrubs, or fill more considerably open plantations. In one place it is entirely simple, without any appendages, any gravel, or any funk fence to separate it from the lawn; and is distinguished only by the richness of its verdure, and the nicety of its preservation. In the arable part it is also of green sward, following the direction of the hedges about the several inclosures: these hedges are sometimes thickened with flowering shrubs; and in every corner or vacant space, is a rosary, a clove or an open clump, or a bed of flowers: but if the parterre has been rifled for the embellishment of the fields, the country has on the other hand been searched for plants new in a garden; and the shrubs and the flowers which used to be deemed peculiar to the one, have been liberally transferred to the other; while their number seems multiplied by their arrangement in so many and such different dispositions. A more moderate use of them would, however, have been better; and the variety more pleasing, had it been less licentious.

But the excess is only in the borders of the walk; the scenes through which it leads are truly elegant, every-where rich, and always agreeable. A peculiar cheerfulness overspreads both the lawns, arising from the number and the splendor of the objects with which they abound, the lightness of the buildings, the inequalities of the ground, and the varieties of the plantations. The clumps and the groves, though separately small, are often massed by the perspective, and gathered into considerable groups, which are beautiful in their forms, their forms, and their positions. The brow of the hill commands two lovely prospects: the one gay and extensive, over a fertile plain, watered by the Thames, and broken by St. Anne's Hill and Windsor Castle; a large mead, of the most luxuriant verdure, lies just below the eye, spreading to the banks of the river; and beyond it the country is full of farms, villas, and villages, and every mark of opulence and cultivation. The other view is more wooded: the steeple of a church, or the turrets of a seat, sometimes rise above the trees; and the bold arch of Walton Bridge is there a conspicuous object, equally singular and noble. The inclosures on the flat are more retired and quiet; each is confined within itself; and all together they form an agreeable contrast to the open exposure above them.

With the beauties which enliven a garden are every-where intermixed many properties of a farm: both the lawns are pastured; and the lowings of the herds, the bleating of the sheep, and the tinklings of the bell-wether, resound through all the plantations: even the clucking of poultry is not omitted; for a menagerie of a very simple design is placed near the Gothic building: a small serpentine river is provided for the water-fowl; while the others stray among the flowering shrubs on the banks, or frigate about the neighbouring lawn: and the corn-fields are the subjects of every rural employment, which arable land from seed-time to harvest can furnish. But though so many of the circumstances occur, the simplicity of a farm is wanting; that idea is lost in such a profusion of ornament; a rusticity of character cannot be preserved amidst all the elegant decorations which may be lavished on a garden.

Experimental Farm, a new establishment proposed by Sir John Sinclair, bart. on a very extensive plan, for the purpose of improving agriculture by proper experiments.

This new institution is to be called "THE PLOUGH, or JOINT STOCK FARMING SOCIETY, for the Purpose of ascertaining the Principles of Agricultural Improvement." There is every reason to hope, that this project will meet the most ample success; for, independently of the advantage which the public may expect to derive from the employment of a large capital in experimental farms, conducted and supervised by the most eminent and enlightened agriculturists, those who shall be induced to subscribe to the plan have a fair and reasonable prospect of seeing themselves not only reimbursed their original deposit, but of being rewarded by a handsome accumulation. Among the most distinguished promoters of the plan are, the Dukes of Argyll, Bedford, and Somerset; the Earls of Egremont and Wemyss; Lords Macdonald and Ranelagh; the Bishops of Llandaff, the Lord Mayor of London, Sir John Call, Sir James Colquhoun, Sir James Norcliff Innes, Sir John Macpherson, and Sir Charles Middleton; and several gentlemen of large property and great knowledge.

The outlines of this plan, which, by the permission of Sir John Sinclair, were presented to the public in the British Magazine, are as follow:

I. The proposed capital.

1,600 shares at 50*l.* each - - - *£*. 80,000.

It is also intended to admit half shares at 25*l.* each; but the persons holding them, though they will have a right to partake in the pecuniary advantages of the institution, will not be entitled to vote in the choice of directors. The number of shares which each person may hold not to be restricted. The directors to be annually chosen in London, and to meet there. The books of the society to be always open to the inspection of subscribers.

II. Proposed Expenditure.

1. To establishing eight experimental, arable, and grazing farms, in the neighbourhood of London, and in different parts of the kingdom, at 4,000 <i>l.</i> each	<i>£</i> . 32,000
2. To ditto two upland farms, for improving mountain sheep, at 1,500 <i>l.</i> each	3,000
3. To purchasing 5,000 acres, inclosing and planting with, larch, fir, and other trees, and other expenses attending the same	35,000
4. To a contingent fund, for incidental and unforeseen expenses	10,000
	<i>£</i> . 80,000

III. Ultimate Return.

1. Sale of stock, crop, and implements, on the experimental farms, at the conclusion of 21 or 30 years, or any other period fixed by the society	<i>£</i> . 35,000
2. Value of 5,000 acres of land, the buildings erected thereon, and of 1,250,000 larches, fir, and other trees, at the conclusion of 30 years	218,000
3. Principal of a contingent fund, on the supposition that the interest will defray all expenses of management, &c.	10,000

Total - - - *£*. 263,000

Which is above thrice the original capital. In addition to the ultimate return, the subscribers will, in the interim, enjoy the following advantages, namely:

1. An account of the proceedings of the society annually transmitted to them;
2. The privilege of visiting the experimental farms, either

in their own neighbourhood, or wherever established by the society:

3. The right of nominating persons to be instructed at the different agricultural academies proposed to be erected at each experimental farm; and,

4. A division of the annual profit that may arise from the experimental farms.

It is also intended to keep up such a connection with the Board of Agriculture, and the various societies formed for agricultural purposes in the kingdom, as cannot fail to be attended with the most important advantages, both to the society itself, and to the farming interest in general.

Conditions of the Subscription.

1. No subscriber shall be compellable to pay his subscription, or shall incur any expense whatever, unless the purposes of the institution are actually carried into effect:

2. The capital of 80,000*l.* shall not be increased, without the consent of a majority of subscribers:

3. The society shall be established by charter, or by act of parliament, or by deed enrolled, so as to prevent the possibility of any demand beyond the sum subscribed:

4. The shares shall be transferable from the time the society is established, and the sums subscribed payable by instalments, to be determined on at a general special meeting of the subscribers, and issued solely under the authority of directors or trustees, appointed by the society for that special purpose.

In recommendation of his proposal, the worthy baronet has deflected with great force and ingenuity on the advantages of experimental farms. He establishes as a principle, that the art of agriculture can never be brought to any high degree of perfection, unless by experiments, accurately tried, and persevered in for some time. In support of this opinion, he refers to the writings of Arthur Young, Marshall, and Dr. Francis Home. From the increasing population of London, and of other large towns in the kingdom, Sir John observes, it is impossible they can be supplied with provisions at a reasonable rate, unless agriculture is brought to a high degree of perfection. At present the nation depends on foreign industry and cultivation for a part of its subsistence, and we are periodically visited with a scarcity of food, which increases the expense of living to every family in the kingdom, and loads the rich with heavy additional burthens to maintain the poor, and to preserve them from the miseries of famine. A small portion of that sum, the exaction of which thus becomes so frequently necessary, were it properly applied to the improvement of agriculture, would soon enable this country to feed itself, and, indeed, would put it in the power of the farmer to supply the public with provisions at a reasonable rate. Hence it is evident, that every man who pays 1*l.* instead of 9*d.* for a loaf of bread, or 10*s.* in the pound instead of 2*s.* for poor-rates, ought to consider himself essentially interested in promoting agricultural improvements, and ought, for his own interest, to support any measure calculated for that purpose, as far as his circumstances will permit.

There is scarcely any part of the kingdom where greater quantities of waste and unproductive land are to be found than in the neighbourhood of London, or ground, in many instances, more capable of improvement. It is to be hoped that the general bill of inclosure will soon pass, in consequence of which those wastes will be divided. But that will be of little avail, unless the means of improving them are ascertained. When Enfield Chase was divided, many persons, from ignorance, suffered considerable losses in attempting to improve

* The experimental farms might be given up at the end of 21 years, and that part of the property divided. The plantations, probably, had better be retained for nine or ten years longer.

portions of the waste; whereas had the principles of improvement been accurately ascertained by means of experimental farms, the purchasers would have improved the land greatly to their own, and to the public benefit.

Sir John further recommends his plan by stating the numerous advantages, in point of knowledge and rational recreation, which will result from it to men of business who have acquired fortunes by the pursuit of their professions in cities, and to those who make temporary excursions into the country, but return disgusted for want of some interesting avocation or laudable pursuit.

In explanation of the manner in which the plan is to be carried into execution, it is said, that although a capital of 80,000*l.* would be necessary, yet from 10,000*l.* to 20,000*l.* will be sufficient to give it a fair beginning, either with an experimental farm, or an extensive plantation, or with both, in the neighbourhood of the metropolis. With such a sum the project will proceed; for however desirable it might be to carry a great scheme into execution, because it commands the attention of those who take a share in the management of it, yet the important object is, to lay a solid foundation, which may, according to circumstances, be afterwards extended. And it is suggested, that when once a capital is embarked, and a farm established sufficient to secure share-holders from eventual loss, there is abundant room to hope, that the example of the metropolis will be followed, and a correspondence established in all parts of the kingdom.

With the honest zeal resulting from conviction, Sir John proceeds to remove the presumable objections to his plan: first, *that no experimental farm is necessary.* In answer to this he observes, that the value of new inventions cannot be correctly estimated without such establishments, nor will it be possible to ascertain what practices ought to be avoided, and what ought to be pursued. The former is as important to be known as the latter, yet seldom communicated to the public, because the farmer is, in general, ashamed of acknowledging his want of success; and, indeed, where his experiments answer, they are frequently concealed, lest others should avail themselves of such discoveries. The object of an experimental farm, however, is, to ascertain facts, and to publish them; and as much credit would be acquired by an intelligent and public-spirited society for their exertions in detecting errors, as in proving facts likely to be useful.

Second, *that there are many experimental farms now carried on by individuals, which will answer the same purpose.* These are more properly to be accounted *pattern farms*, for the advantage of their own immediate neighbourhood, than experimental ones, in the strict sense of that word. In order to render indeed experimental farms generally useful, the farms must be open to the inspection of the public; the account of each experiment must be regularly published, and every experiment, likely to affect the cultivation of any part of the kingdom, tried with the utmost precision. It cannot be expected that persons whose attention is necessarily directed to other objects can renounce every other pursuit, and devote themselves exclusively to the conducting of experiments; whereas, when an experimental farm is once established, it will soon be proved by the evidence of facts, 1st, What is the best mode of rendering arable land productive, and the proper rotation of

crops in all soils and situations. 2d, What is the best system for the management of grass lands. 3d, What are the most useful implements of husbandry. 4th, What are the most profitable breeds of animals, and the best and cheapest modes of rearing, feeding, and fattening them. 5th, What is the best plan for rendering waste or barren land productive. These are points of infinite consequence, which never have yet, and indeed never can be ascertained, unless by means of farms appropriated for that special purpose: it will require, it is true, the unceasing attention of an intelligent manager; and the experiments, in order to be relied on, must be made with almost mathematical accuracy and strictness. The expense also must be considerable; but the ultimate advantage to the public must be so great, as amply to compensate for any trouble, or cost, which may attend the execution*.

Third, *that it would be difficult to find managers.* This objection, not referring so much to the principle of the undertaking, as to a contingent fact, constituting a difficulty, is answered by the personal assertion of Sir John, that he knows some who would carry on the undertaking with zeal and energy, and take shares as a security for their good behaviour, and a pledge of their being interested in its success. After decanting on the benefits which will accrue, both to the public and the manager, and which will operate as a stimulus on his activity and integrity, while every possibility of fraud is cautiously precluded, the following remark is made:—In regard to the particular plan of experiments to be pursued, the following measures may be adopted: as soon as a farm is taken, an accurate plan of it should be obtained, distinguishing the different soils, and every other circumstance connected with it. Every assistance will then be procured from the best practical farmers in the kingdom, to draw up a regular course of experiments, and a rotation of crops best calculated for the different fields; and such a plan must be rigidly adhered to by the manager, unless the committee of management give directions to the contrary. Thus the manager will only be accountable for the strict execution of the orders he receives; and as those orders will be given in consequence of the most mature consideration, hence the whole system, it is to be hoped, will be carried on with the utmost regularity and correctness: then would there not be a single principle in agriculture that might not be thus ascertained in the space of a few years; and farmers, in future, would have an invariable standard to go by, which they might rely on with certainty.

The fourth and last objection to which an answer is given is, that the profits of the proposed plantation are over-rated. To obviate this supposition, Sir John Sinclair states the great probability that, in thirty years, the value of timber will be greatly enhanced; but, taking it at its present value, there is every reason to consider it greatly under-rated. In proof of this he cites the valuation of the forest of Culores, near Edinburgh, which consists of Scotch firs forty-three years old, and is valued at 93*l.* 15*s.* an acre. Now as larch at thirty years old is as valuable as fir at forty-five, there is every reason to expect that the 5000 acres proposed to be planted will be worth at least 900*l.* an acre, and consequently, instead of 218,000*l.* the sum first stated, will produce 450,000*l.*

This is the substance of a most benevolent, patriotic, and practicable plan, in which individuals, without forgetting for

* For instance, if the question is, What is the best breed of cattle? Their food must be accurately weighed, and a regular account preserved of the whole quantity they eat during the whole course of the experiment. If the question is to ascertain, Whether large or small animals pay best for the food they eat; the experiment must be begun from their birth, and continued till they are slaughtered. In short, almost every experiment of great consequence requires a degree of attention and perseverance, and a duration, in point of time, which can only be expected from a public institution devoted exclusively to that purpose.

One Years Crop on 400 Acres divided into 4 equal Departments.

It is proposed to have the principal Experimental Farm in the immediate vicinage of London, as a model to the rest & for the satisfaction & benefit of the Subscribers in the Metropolis. It is evident that the Crops must vary every Year which cannot be explained by Plate.

SIR JOHN SINCLAIR'S Plans & Elevations of CIRCULAR COTTAGES.

a moment the dictates of prudence, may render a most important service to their country, and become patrons of an institution which future ages (thall revere as the source of innumerable and inexhaustible blessings.

We have copied from Sir John's publication the annexed engravings (Pl. 28.), which represent the distribution of an experimental farm of 400 acres, and a circular cottage, which is recommended as being peculiarly warm and convenient, and, if built of good materials, capable of lasting for ages, with hardly any repair. An additional recommendation of such a building is its cheapness, as it will not, in the northern parts of Scotland, cost more than 30*l*.

FARNABIE (Thomas), son of a carpenter at London, born in 1575, flaid a short while at Oxford; where being enticed to abandon his religion, he went to Spain, and was there educated in a college belonging to the Jesuits. Being weary of their severe discipline, he went with Sir John Hawkins and Sir Francis Drake in their last voyage in 1595. He was afterwards a soldier in the Low-countries; but being reduced to great want, returned to England, where wandering about for some time under the name of *Thomas Bainsafe*, the anagram of his name, he settled at Mattock in Somersetshire, and taught a grammar-school with good reputation. He removed to London, and opened a school with large accommodations for young gentlemen. While he taught this school he was made master of arts at Cambridge, and incorporated into the university of Oxford. Thence he removed, in 1636, to Seven-oaks in Kent; and taught the sons of several noblemen and gentlemen, who boarded with him, with great success, and grew rich. His works gained him reputation. Upon the breaking out of the civil commotions in 1641, he was cast into prison. It was debated in the house of commons, whether he should be sent to America; but this motion being rejected, he was removed to Ely-house in Holborn, and there he died in 1647. Mr. Farnabie was a very eminent grammarian; and many writers have spoken with great approbation of his labours. M. Bayle in particular says, "His notes upon most of the ancient Latin poets have been of very great use to young beginners; being short, learned, and designed chiefly to clear up the text."

FARO, an island of Sweden, near the island of Gothland, about 30 miles in circumference, populous and fertile. The principal town has the same name, and is situate on the S.E. coast. Long. 19. 7. E. Lat. 57. 50. N.

FARO, a sea-port of Portugal, in Algarva, on the gulf of Cadiz, with a bishop's see. It has some trade in almonds, figs, oranges, and wine, and is 20 miles S.W. of Tavira. Long. 7. 48. W. Lat. 36. 54. N.

FARO, FARRO, or FEROS ISLANDS, a cluster of small islands in the Northern Ocean, between 5 and 8° W. long. and 61 and 63° N. lat. They are subject to Denmark. Seventeen are habitable, each of which is a lofty mountain, divided from the others by deep and rapid currents. Some of them are deeply indented with secure harbours, all of them steep, and most of them faced with tremendous precipices. The surface consists of a shallow soil of remarkable fertility; producing plenty of barley, and fine grass for sheep. No trees above the size of a juniper, or stunted willow, will grow here; nor are any quadrupeds to be seen except sheep, and rats and mice, originally escaped from ships. Vast quantities of sea-fowls frequent the rocks, and the taking of them furnishes a perilous employment for the inhabitants. The exports are salt mutton, tallow, goose-fowls, feathers, eider-down, knit wollen waistcoats, caps and stockings. To the S. of these islands is a considerable whirlpool. See *BIRD-Catching*.

FARO OF MESSINA, the strait between Italy and Sicily, remarkable for having the tide ebb and flow every six hours,

with great rapidity, though it is but seven miles over. It is so named, from the faro, or lighthouse, on Cape Faro, and its vicinity to Messina.

FARRIERY (*Encycl.*). This once vulgar art has deservedly been rescued from the hands of ignorance by the labours of the Veterinary College, and its ingenious professor Mr. COLEMAN. (See *COLLEGE, Supp.*) The improved state of Veterinary literature is also a subject of high congratulation to the country; who are now possessed of valuable works on the subject from the pens of the late and present professors of the college; and from Messrs. White, Riding, John Lawrence, Richard Lawrence, and Boardman; to the latter of whom the public is indebted for a VETERINARY DICTIONARY, which comprehends all that is known on the subject of the diseases of horses and cattle, illustrated with excellent engravings of the anatomy of the horse, &c. See *FROG* in this Supplement.

FARRINGTON, a town in Berks, with a market on Tuesday, seated on an eminence, near the Thames, 18 miles W. of Oxford, and 50 W. by N. of London. Long. 1. 27. W. Lat. 51. 44. N.

FARSISTAN; a province of Persia, bounded on the E. by Kerman, on the N. by Irac-Agemi, on the W. by Kufistan, and on the S. by the gulf of Persia. It is very fertile, and famous for its excellent wines, called the Wines of Schiras, the capital of this province. Here are the ruins of Persepolis, perhaps the most magnificent in the world.

FARTACK, a town of Arabia Felix, at the foot of a cape of the same name. Long. 51. 25. E. Lat. 15. 55. N.

FAT (*Encycl.*). A patent has been granted to Mr. Wilson Fitzgerald, of the Inner Temple, for a mode of producing fat or tallow. The process consists in pouring upon animal flesh, of any kind, a sufficient quantity of strong nitrous acid, which decomposes the flesh, and produces the tallow. Or, instead of the nitrous acid, a composition may be employed, consisting of two thirds sulphuric acid, and one third nitrous—or of two thirds nitrous, and one third muriatic or oxy muriatic acid. Or, instead of these, a compound may be used, consisting of lime, sulphate of pot-ash, alum, and pyrites.

FATTIPOUR, a town of Hindoostan Proper, in the province of Agra, where the emperors of Hindoostan, when in the zenith of their power, had a palace. It is 25 miles W. of Agra. Long. 77. 43. E. Lat. 27. 22. N.

FAVIGNANA, a small island, 15 miles in compass, on the W. side of Sicily, with a fort. Long. 12. 25. E. Lat. 38. 16. N.

FAYAL, one of the Azores, or Western Islands, which suffered greatly by an earthquake, in 1764. Its capital is Villa do Horta.

FAYENCE, a town of France in the department of Var, celebrated for its manufacture of earthen ware. It stands near the river Biazon, 10 miles W. of Grasse. Long. 6. 44. E. Lat. 43. 38. N.

FAYETTE, a county of Kentucky, bounded on the N. by the Ohio, on the E. by Bourbon county, and on the S.W. by the river Kentucky. Lexington is the capital.

FAYETTE, a county of Pennsylvania, 37 miles long, and 33 broad. In 1790, it contained 13,325 inhabitants. Union is the capital.

FAYETTEVILLE, a town of N. Carolina, on the N.W. branch of Cape Fear River, 90 miles N.W. of Wilmington, to which that river is navigable for boats.

FAYOUM, a town of Egypt, capital of a province of the same name, 49 miles S.S.W. of Cairo. Long. 30. 39. E. Lat. 29. 27. N.

FE, SANTA, a rich and regularly built city, the capital of New Mexico, and the see of a bishop. It is situate near the source of the Rio del Norte. Long. 108. 48. W. Lat. 36. 50. N.

FE, SANTA, a town of Paraguay, situate at the confluence of the Salade with the Plata, 450 miles S.W. of Assumption. Long. 60. 40. W. Lat. 30. 45. S.

FEAR, CAPE, a cape of N. Carolina, remarkable for a dangerous shoal, called, from its form, the Frying-pan. This shoal lies at the entrance of Cape Fear River, which is formed by two branches, called the N.W. and N.E. branches. These unite above Wilmington, and fall into the Atlantic, below Brunswick. Long. 77. 45. W. Lat. 33. 40. N.

FECAMP, an ancient sea-port of France, in the department of Lower Seine. It had lately a Benedictine abbey, remarkable for its opulence and great privileges. The church is one of the largest in France. *Fecamp* is 24 miles N.E. of Havre-de-Grace. Long. 0. 23. E. Lat. 49. 37. N.

FELDKIRCHE, a trading town of Germany, capital of a county of the same name, in Tirol. It is seated on the river Ill, near its entrance into the Rhine, 15 miles E. of Appenzel. Long. 9. 40. E. Lat. 47. 10. N.

FELICUDA, one of the Lipari Islands, in the Mediterranean, 28 miles W. of Lipari. The inhabitants preserve rain-water in cisterns, there being no spring in the island.

FELIX, Sr., an island in the S. Pacific Ocean, N.N.W. of Juan Fernandez. Long. 86. W. Lat. 26. S.

FELLETTIN, a town of France, in the department of Creuse, noted for its manufacture of tapestry. It is 20 miles S.S.W. of Evaux, and 21 S.S.E. of Gueret. Long. 2. 6. W. Lat. 45. 53. N.

FELLEN, a town in the Russian government of Riga, seated on a river of the same name, 62 miles S.E. of Revel. Long. 24. 5. E. Lat. 58. 22. N.

FELSBERG, a town of Germany, in the principality of Hesse Cassel, with an ancient castle on a rock, 12 miles S. of Cassel.

FELTRI, an episcopal town of Italy, in the Trevisano, capital of a district of the same name. It is seated on the Adona, 40 miles N. of Padua. Long. 11. 55. E. Lat. 46. 3. N.

FELTRIA (anc. *geog.*), a town on the borders of Rhaetia towards Italy. Now *Feltre*, in the territory of Venice, on the Piava. Long. 12. 16. E. Lat. 46. N.

FEMEREN, a fertile island or Denmark, in the Baltic, three miles from the coast of Holstein.

FENESTRELLE, a town and fort of Piedmont, in the valley of the Vaudois. It was taken by the Duke of Savoy, from the French, in 1708, and ceded to him by the treaty of Utrecht. It is 18 miles W. of Turin. Long. 7. 21. E. Lat. 45. 10. N.

FERABAD, a town of Persia, capital of the province of Mazanderan, seated among the mountains which bound the Caspian Sea to the S. and 12 miles from it. Shah-Abbas often spent his winters here. It is 130 miles W. of Astrabad. Long. 53. 21. E. Lat. 37. 14. N.

FERABAD, a town of Persia, two miles from Isfahan, and extending almost three miles along the banks of the Zenderoad. It was built by Shah-Abbas, who brought the Armenians here from the preceding town, after they had revolted from the Turks.

FERCULA, or *FORCULA*, a town of Biledulgerid, and the principal place of a district. It is 50 miles W. of Sugulmeffa. Long. 4. 30. W. Lat. 31. 40. N.

FERDINAND V. king of Spain, called *the Catholic*, which title was continued to his successors. He married Isabella of Castile, by which that kingdom was united to the Spanish crown. This illustrious couple laid the foundation of the future glory and power of Spain. The conquest of Grenada, and the discoveries of Christopher Columbus, make this reign a celebrated æra in the history of Spain. He died in 1516, aged 63.

FERE, a town of France, in the department of Aisne, famous for its powder-mill, and school of artillery. Near this town is the castle of St. Gobin, famous for its manufacture of fine plate-glass. *Fere* is seated at the confluence of the Sere and Oise, 20 miles N. of Soissons, and 75 N.E. of Paris. Long. 3. 25. E. Lat. 49. 29. N.

FERENTINO, or *FIRENTO*, an episcopal town of Italy, in Campagna di Roma, seated on a mountain, 44 miles S.E. of Rome. Long. 13. 27. E. Lat. 41. 46. N.

FERENTINUM (anc. *geog.*), a town of the Hernici in Latium, which the Romans, after subduing that nation, allowed to be governed by its own laws. Now *Ferentino*, an episcopal city in the Campania of Rome. Long. 14. 5. E. Lat. 41. 45. N.

FERENTUM, or *FORENTUM* (anc. *geog.*), a town of Apulia in Italy. Now *Forenza*, in the Basilicata of Naples.

FERMO, an ancient town of Italy in the marquise of Ancona, with an archbishop's see. It is seated near the gulf of Venice, 17 miles S.E. of Macerata. Long. 13. 50. E. Lat. 43. 7. N.

FERNANDO NORONHA, an island near the coast of Brazil, subject to the Portuguese. Long. 32. 33. W. Lat. 3. 56. S.

FERNANDO Po, an island of Africa, 25 miles W. of the coast of Benin. It is 30 miles long, and 20 broad. Long. 3. 3. E. Lat. 3. 6. N.

FERNELIUS (John), physician to Henry II. king of France, was born in Picardy, in the latter end of the 15th or the beginning of the 16th century. Being sent to Paris to study rhetoric and philosophy, he applied himself in a most intense manner. All other pleasure was insipid to him. He cared neither for play nor for walking, nor for entertainments, nor even for conversation. He read Cicero, Plato, and Aristotle. The reading of Cicero procured him this advantage, that the lectures he read on philosophical subjects were as eloquent, as those of the other masters were barbarous at that time. He also applied himself very earnestly to the mathematics.

This continual study drew upon him a long fit of sickness, which obliged him to leave Paris. On his recovery, he returned thither with a design to study physic; but before he applied himself entirely to it, he taught philosophy in the college of St. Barbara. After this he spent four years in the study of physic; and, taking a doctor's degree, confined himself to his closet in order to read the best authors, and to improve himself in the mathematics; that is, as far as the business of his profession would suffer him. Never was a man more diligent than Fernel. He used to rise at four o'clock in the morning, and studied till it was time either to read lectures or to visit patients. He then examined the urine that was brought him; for this was the method of those times, with regard to the poor people, who did not send for the physician. Coming home to dine, he flung himself up among his books, till they called him down to table. Rising from table, he returned to his study, which he did not leave without necessary occasions. Coming home at night, he did just as at noon: he staid among his books, till they called him to supper; returned to them the moment he had supped; and did not leave them till eleven o'clock, when he went to bed.

In the course of these studies, he contrived mathematical instruments, and was at great charges in making them. But his wife murmuring at the expence, he dismissed his instrument-makers, and applied himself in good earnest to practise physic. But as visiting patients did not employ his whole time, he read public lectures upon Hippocrates and Galen. This soon gained him a great reputation through France and in foreign countries. His business increasing, he left off read-

ing lectures; but as nothing could make him cease to study in private, he spent all the hours he could spare in composing a work of physic, *Physiologia*, which was soon after published. He was prevailed with to read lectures upon this new work, which he did for three years: and undertaking another work, which he published, *De venesectione*, he laid himself under a necessity of reading lectures some years longer, in order to explain this new book to pupils.

While he was thus employed, he was sent for to court, in order to try whether he could cure a lady, whose recovery was despaired of. He was so happy as to cure her; which was the first cause of that esteem which Henry II. who was then but dauphin, and was in love with that lady, conceived for him. This prince offered him, even then, the place of first physician to him; but Fernel, who infinitely preferred his studies to the hurry of a court, would not accept the employment. When Henry came to the throne, he renewed his intreaties: but Fernel repented, that the honour which was offered to him was due, for several reasons, and as an hereditary right, to the late king's physician; and that, as for himself, he wanted some time to make experiments concerning several discoveries he had made relating to physic. The king admitted this: but as soon as Francis I.'s physician died, Fernel was obliged to go and fill his place at Henry II.'s court. And here just the contrary to what he dreaded came to pass: for he enjoyed more rest and more leisure at court, than he had done at Paris; and he might have considered the court as an agreeable retirement, had it not been for the journeys which the new civil war obliged the king to take. He died in 1558, leaving behind him a great many works, besides what have been mentioned; as, *De abditis rerum causis*, seven books of Pathology, a book on remedies, &c. They have been printed several times; with his life prefixed, written by William Plantius his disciple.

FEROE ISLANDS. See **FARO**.

FERRENDINA, a town of Naples, in Basilicata, near the river Sifanto, 25 miles S.W. of Matera. Long. 16. 34. E. Lat. 40. 40. N.

FERTE-ALAIS, a town of France, in the department of Seine and Oise, 18 miles S. of Paris. Long. 2. 27. E. Lat. 48. 30. N.

FERTE-BERNARD, a town of France, in the department of Sarthe, seated on the Huise, 20 miles N.E. of Mans. Long. 0. 30. E. Lat. 48. 3. N.

FESTENBERG, a town of Silesia, in the principality of Oels, 14 miles N.W. of Wartenburg.

FETHARD, a borough of Ireland, in the county of Tipperary, eight miles S.E. of Cashel, and 86 S.W. of Dublin.

FETHARD, a town of Ireland, in the county of Wexford, on the coast, 81 miles S. of Dublin. Long. 7. 3. W. Lat. 52. 10. N.

FEVER (*Encycl.*). It is well known not only to medical men but to others who have experienced the direful effects of contagious fevers, that in small, close, and dirty rooms they infect a very great proportion of mankind; not less than 26 out of 27, or a still higher proportion. In a large airy, clean apartment, however, even putrid fevers are seldom or never infectious. When this poisonous vapour is much diluted with fresh air, it is not noxious.—From a large collection, and an attentive consideration, of facts relative to this distemper, have been formed the following rules, which cannot be too generally known.

1. As safety from dangers entirely depends on cleanliness and fresh air, the room door of a patient ill of an infectious fever, especially in the habitations of the poor, should never be shut; a window in it, during the day, ought to be frequently opened. Such regulations would be highly useful, both to the

patient and nurses; but are particularly important previous to the arrival of any visitor.

2. The bed-curtains should never be close drawn round the patient; but only on the side next the light, so as to shade the face.

3. Dirty clothes, utensils, &c. should be frequently changed, immediately immersed in cold water, and washed clean when taken out of it.

4. All discharges from the patient should be instantly removed. The floor near the patient's bed should be rubbed clean every day with a wet mop, or cloth.

5. The air in a sick-room has, at the same time, a more infectious quality in some parts of it than in others. Visitors and attendants should avoid the current of the patient's breath,—the air which ascends from his body, especially if the bed-curtains be closed,—and the vapour arising from all evacuations. When medical or other duties require a visitor to be placed in these situations of danger, infection may be frequently prevented by a temporary suspension of respiration.

6. Visitors should not go into an infectious chamber with an empty stomach; and in doubtful circumstances, on coming out, they should blow from the nose, and spit from the mouth, any infectious poison, which may have been drawn in by the breath, and may adhere to those passages.

The Society for bettering the Condition of the Poor have published the preceding rules, which were extracted from a manuscript of Dr. Haygarth's, with his permission. They are intended to enable medical and clerical visitors of the sick to perform their important duties with safety to themselves, and are printed upon a separate sheet, by the Society, with a view to their being distributed, so that a printed copy may be put up in every house where there is an infectious fever.

Houses of recovery for the reception of poor persons affected with typhus fever were first opened in Manchester; and the example has lately been followed in London and many other places. See **HOUSE OF RECOVERY**, in this Supplement.

FEURS, an ancient town of France, in the department of Rhone and Loire, seated on the Loire, 23 miles S.W. of Lyons.

FEZ, a kingdom of Barbary, 125 miles in length and breadth; bounded on the W. by the Atlantic Ocean, on the N. by the Mediterranean Sea, on the E. by Algiers, and on the S. by Morocco and Taflet. The air is temperate and wholesome, and the country full of mountains, particularly to the W. and S. where Mount Atlas lies; but it is populous and fertile, producing citrons, lemons, oranges, dates, almonds, olives, figs, raisins, sugar, honey, flax, cotton, pitch, and corn in abundance. The inhabitants breed camels, bees, sheep, and the finest horses in Barbary.

FIANO, a town of Italy, in the patrimony of St. Peter, seated on the Tiber, 15 miles N. of Rome.

FIANONA, a town of Venetian Istria, seated on the gulf of Camero, 17 miles N. of Pola.

FICHERULOLO, a fortified town of Italy, in the Ferrarese, seated on the Po, 12 miles W. of Ferrara. Long. 11. 31. E. Lat. 45. 6. N.

FICHTELBERG, a mountain in Bohemia, which extends from near Barchuth to Eger, about 16 miles. It is one of the highest mountains in Germany.

FICTION (*Encycl.*). An ingenious writer in the British Magazine for 1800 makes the following curious remarks on the sources of poetic and romantic fiction.

"I accord," says he, "with Mr. Franklin's observation, that the tale of Camarupa and Camatata bears internal evidence of an Indian origin, yet two or three passages would induce one to suppose that it is not of very great antiquity, or rather, that it has received some alteration from its Persian translator. The race of men with leathern feet, the persecu-

tors of Camarupa and others, Mr. Franklin says, are even now supposed to inhabit the northern parts of Indofan : nor am I disposed to question their existence. The story in which they appear (p. 74) is evidently founded upon, or borrowed from, that in the Arabian Nights, where, like Camarupa, Sindbad with a stone dashes out the brains of his unmerciful rider, 'the old man of the sea.' The *ouran-outangs*, as Mr. Hole conjectures in his Remarks on the Arabian Nights, are undoubtedly the species alluded to; their feeding on fruit only in either tale is a striking characteristic. The *ouran-outangs* (or *γάρδαί*) in Hanno's remarkable voyage, words of the same import as *ouran-outang*, *homines sylvestres*, are evidently of the same species. Our early voyagers to the same coast which Hanno visited, called this animal *pongo*, or the *giant-ape*; and it was sometimes literally represented as of gigantic stature. Purchas, in his Pilgrimages, mentions his having been informed that their height was like a man's, but their bignesse twice as great. We have been in some old romance, but forget where, the *Pongo* introduced as a savage giant, overthrowing the ranks of battle with his knotty club. The account given of it by Battell, who visited the coast of Africa in 1603, is curious and just, though somewhat exaggerated. (See Purchas' *Pilgrimages*, vol. ii. 982.) They are described in Hanno's voyage as covered with hair, flying to precipices, and defending themselves with stones. A circumstance recorded of their lesser brethren, by Strabo (Geog. xv. p. 710, Paris ed.) And which is noticed likewise in Churchill's Voyages (vol. iii. 143).

"Sir John Mandeville's 'flynnyd folk with rougher heir as a rougher best, faw only the face and the pawme of the hond,' which he meets with in one of the isles of Ynde, are of the same family. And those with short dog-tails, mentioned by Marco Paulo as inhabiting a district called *Lambri*, belong to the same race. Invenitur etiam in hoc regno qui caudas habent ut canes, longitudo inius, palmi, et hi in civitatibus non habitant, fed in montibus. (L. iii. c. 18.) By *Lambri*, Sumatra is probably intended, often called Java Minor by early European travellers. *Lambri* is one of its Indian appellations, and Mandeville seems to allude to it by the name of *Lamaray*. His account indeed often wonderfully coincides with that of the Venetian traveller, and perhaps he borrowed from him. However that may be, this *pustoral race*, which very wisely shunned 'towering cities and the busy hum of men,' were, we may safely conclude, the ancestors of the *orang coboo* and *orang googoo* mentioned by Mr. Mariden as inhabiting the interior parts of Sumatra. The natives of the island, he tells us, suppose the latter to be endued with the gift of speech. After having allowed them to belong to the human species, 'their having a language peculiar to themselves (I think these are Mr. Mariden's words) appears a natural consequence.' Whoever wishes to see their claims to humanity stated and enforced, is referred to their learned advocate, Lord Kaimes' Origin of Languages, vol. i. b. 2.

"Camarupa's aerial excursion to the mountain of *Caf* (Caucasus), and the incidents there, resemble the marvellous narrative of Aboulfauaris : and so do Mitra Chandra's adventures among the Genii, 'who delight in blood.' A country inhabited by women, called *Threa Rai*, occurs likewise in the Persian tales; and it is observable, that Marco Paulo testifies to the existence of two islands in the Indian ocean, one inhabited by men, the other by *women only** (l. iii. c. 37). Again, the enormous whale in Camarupa is not unlike that in Sindbad; and the daughter of the Fairy Queen, who, in 'taking her accustomed tour through the air to view the different parts of the earth,' beholds the prince whilst asleep, and

is struck with admiration at his beauty (p. 61), extremely resembles a fiter fairy, who makes her aerial tour at the opening of Camaralzaman's story in the Arabian Nights. In either tale, a child is granted to the ardent desires of the royal parent, through the intercession and prayers of religious persons. This circumstance is to be found in more than one story of the latter collection; and I believe in various oriental tales. But does it not rather militate against the predestinarian system, so universally adopted in the East? For had not those religious persons been prevailed upon to offer up their prayers in behalf of their then childless sovereigns, we are to conclude that no child in future would have been born to them : therefore they counteracted destiny! Probably, however, a genuine predestinarian will hold in contempt such sceptical objections, and insist that the monarch's requests, the dervise's intercessions, and birth of the children, were links of the same chain, all equally pre-ordained, and resulting from inevitable necessity.

"The mode by which Camaralzaman and the Princess Badoura become mutually enamoured of each other, has not only a counterpart in the Indian tale, but also in the *Oberon* of Wieland. The interview in the Arabian Nights, by means of which the hero and heroine contract a mutual affection, is indeed real, but that of Camarupa and Camalata, and that of Sir Huon and Rezia, is visionary. (See *OBERON*, cant. iii. ft. 6. cant. iv. ft. 49.) In each instance, however, it is effected by supernatural means : *fairies* intervene, and the result is the same. Whether this incident in Wieland is taken from the old romance of Sir Huon of Bourdeaux, we know not, but think it highly probable. From Spenser's mentioning the night and fairy in conjunction, we may reasonably infer, that they are introduced together in that or some other ancient tale of chivalry. Guyon, he tells us,

—Knight-hood took of good Sir Huon's hand,
When with King Oberon he came to fairy land.

B. II. c. 1. ft. 6.

"The story of January and May is narrated by Wieland in the 6th canto, in exactly the same manner as by Chaucer and Pope; yet we cannot help suspecting that it is to be found likewise in the old romance, and from thence copied by Chaucer. The idea is strengthened by the following note of Mr. Stevens, towards the conclusion of *The Midsummer Night's Dream*. 'I have been informed that the originals of Shakspeare's *OBERON* and *TITANIA* are to be sought (we trust he means found) in the ancient French romance of *Huon de Bourdeaux*.'

"Pluto and Proserpine are in Chaucer 'the king and queene of faerie' : and the former, like Oberon in Wieland (canto vi. ft. 87), appears well acquainted with the Bible, and quotes Solomon's sarcastic observations on the fair sex in a familiar manner. (See Tyrwhitt's ed. of Chaucer, vol. ii. l. 10163.) Proserpine (not yet converted from paganism it may be presumed) 'tweres by her modre Ceres' sowl,' and egregiously abuses the sapient king as a 'lechour and an idolastre;' and declares, that

She sete nat of all the wilunie
That he of women wrote, a *boterflye*!

"But let us return from the strange mixture of absurdity, keen wit, and strong sense, which so frequently chequers the pages of our primitive bard. If the preceding conjecture be right, that we are to look for the origin of Chaucer's January and May, of his Pluto and Proserpine, of Shakspeare's Oberon and Titania, in the old French romance of Sir Huon of Bourdeaux, a pertinent quotation from it would be extremely grate-

* See also the Two Mahomedans' Account of India in the 9th Century, published by Renaudot, p. 1.

ful, not only to your correspondent Cassius, but to many an antiquary who does not look with contempt on romantic lore. In that case, however, though I apprehend the French legend is supposed to have been written in the 13th or 14th century, I should not readily allow that part of the story to be of European manufactory. It may, as Mr. Hole in his Remarks on the Arabian Nights supposes of some similar eccentric fictions, have been imported by our adventurous crusaders; or, perhaps at a much earlier era, may have been introduced by some colony from the eastern world into European districts. Sir William Jones says, 'I confidently affirm, that the *Goths* and *Hindus* had originally the same language, gave the same appellations to the stars and planets, adored the same false deities, performed the same bloody sacrifices, and professed the same notions of rewards and punishments after death.' *Asi. Diss.* vol. iii. 15. Among the Gothic nations, long before the commencement of the crusades, beings of a similar nature to fairies in our popular mythology had an existence. In the northern Sagas they are styled *dvergur*, or *dwarfs*, and perform actions surpassing human nature. They were, probably, of eastern origin, and brought to England by our Saxon ancestors.

"Mr. Hole observes, that Chaucer's January and May (and he might have added the ninth novel in Boccaccio's seventh Decameron) is to be traced in the tales of *Inatulla*; and he is supposed to have derived it from the *Bramins*. The tales to which he refers were merely paraphrased by Dow; but since that time have been translated by Mr. Scott, and entitled the *Bahar-Danush* of *Binnat-Oollah* (*Inatulla*). In them, however, the similitude will be found equally obvious, if you consult lesson 4. vol. ii. p. 64: and in the subsequent lesson another tale occurs concerning the supposed miraculous restoration of a nose, resembling an incident in *Massenger's Guardian*, and traced by Mr. Hole to the *Hecetopades*, styled by Sir William Jones 'the most beautiful if not most ancient collection of apologues in the world.'

"That Sir Huon of Bourdeaux and other ancient legendary tales were commonly derived, through some medium or other, from an Asiatic, perhaps an Indian, origin, I have little doubt. The primary notice of Oberon in our language (and seemingly from Sir Huon of Bourdeaux) we find in Spenser: and among the first who mention Titania as co-partner in his royalty, is Shakespeare in the *Midsummer Night's Dream*. He invests Mab, however, with regal honours in his *Romeo* and *Juliet*; and Mab in Drayton's *Nymphidia*, a performance which exhibits much sprightly humour and original fancy (and in other poems of that age), shares imperial dignity with Oberon. Where we are to look for their first introduction into ideal existence, or the derivation of either name, is, I believe, not easily to be ascertained. The existence, however, of a fairy queen in the days of Elizabeth was the popular creed, and had continued to probably from an age long preceding that of Chaucer; who, in order to ridicule such idle fancies, represents Sir Thopas as fully determined that

'An elf queen should his Lemman be.'

"And we find that not only Prince Arthur in Spenser's beautiful legend, but the aspiring Abel Druggier in Jonson's *Alchemist*, had some pretensions to her majesty.

"It is rather strange, however, that during this period the elf queen should not have acquired a decided appellation. Oberon, after Spenser's time, possessed, we apprehend, his regal prerogative without a competitor. But Richard Johnson, the contemporary of Shakespeare, and Drayton in his *Honourable History of the Seven Champions of Christendom*, divests Titania of her sovereignty, converts the Fancy's midwife into a fairy midwife (a circumstance however not dissimilar to

ancient superstition), whom he denominates *Proserpine*, and reinfates in her shadowy domains.

"Though the existence of such imaginary beings, as the elfine queen and her tiny subjects,

'These antique fables and those fairy toys,'

no longer obtains credence among the least enlightened minds, yet the extensive influence of that idea in former ages affords a subject not uninteresting to speculative minds, who wish to investigate the progress of traditional fiction and human credulity. Johnson evidently compiled from old metrical romances; and the passage to which we allude in respect to *Proserpine* is, her attendance on *Sabra* in the hour of her delivery; which remarkably coincides with the *accouchement* of *Rezia* in *Oberon*, where *Titania* is present on the same occasion. We can with as little reason suppose that Wieland ever consulted the *Seven Champions of Christendom*, as that Johnson in a decided compilation, invented one of the most singular incidents recorded in it. The corresponding passage is managed with much delicacy by Wieland in his *Oberon*, and we are convinced our readers would not be displeased at our making some extracts from it, did not the peculiarity of the circumstance warrant the transcription. We should be pleased indeed to see another *Epic Romance*, of a similar complexion and superior order, undertaken by its translator. The eccentric spirit of the *Orlando Furioso*, its wild transitions from humour to sublimity, and their not unrequited mixture in the same passage, would, we trust, receive ample justice from the lively pen of

Mr. Sotheby. Huggins's faithful but tame translation, would prove of service to any one not familiar with the Italian language. According to Cervantes's happy image, it exhibits indeed the wrong side of the tapestry, but not a thread is misplaced or lost. To proceed to the comparison, we were going to say contrast, but notwithstanding the wildness of Johnson's tale, and bombast of his language, some rude graces, a luxuriance and vigour of fancy, gratify the imagination at the expence of judgment.—St. George and *Sabra* are represented as wandering in a mighty wilderness, overgrown with lofty pines and cedar-trees, and many huge and mighty oaks, the spreading branches whereof seemed to withhold the light of heaven from their untrodden passages, and tops, for exceeding height, to reach into the element. The inhabitants were sylfians, satyrs, fairies, and other wood nymphs, which by day sported up and down the forest, and by night tended the pleasure of *Proserpine*, the fairy queen. The music of silver-sounding birds so cheerfully resounded through the woods, and the whistling wind made such melody amongst the leaves of trees, that it ravished their senses like harmony of angels, and made them think they had entered the shades of gladiome *Elysium*: one while they wondered at the beauty of the woods, which nature adorned with a summer's livery; another while at the green and fragrant grass drawn out in round circles by fairies' dances. Here, 'till thrice three times the silver moon had renewed her borrowed light,' wandered the disconsolate *Sabra* and afflicted champion. 'Before the painful hour of her delivery approached, he had provided her a bower of vine branches, which he erected between two pleasant hills: where, instead of a princely cabinet, behung with arras and rich tapestry, she was constrained to suffice herself with a simple lodging covered with roses and other fragrant flowers. Her bed was made of green moss and thistle-down, beset curiously round about with olive branches and the sprigs of an orange-tree, which made it seem more beautiful than *Flora's* pavilion or *Diana's* mansion.' *Sabra*, however delighted the might be with the elegant bower constructed by the knight, requests his absence; for the time approached when, as no other *accouchement* was to be expected, the imagined that some

Friendly fairy might witness her distress, and lend her assistance. According to her wish, Proserpine attends in *propria persona*, and three lovely boys are introduced into the world: but let Sabra tell her own story: 'The winds carried my groans to every corner of this wilderness, whereby both trees and herbs assisted my complaints; beasts, birds, and feathered fowls, seemed to pity my moans: but in the midst of my torments, when my soul was ready to forsake this worldly habitation, there appeared to me a queen crowned with a golden diadem, in state and gesture like imperious Juno, and in beauty to divine Diana: her garments for bravery seemed to stain the rainbow in her brightest hue, and for diversity of colours, to surpass the flowers in the fields: on her attended many beautiful nymphs, some clad in garments in colour like the crystal ocean, some in attire as gallant as the pleasant rose, and some more glorious than the azure firmament. Her wisdom might compare with Apollo's, her judgment with Pallas', and her skill with Lucina's.—In short, at the appearance of the benevolent elixir queen, and her beautiful attendants, the pains of Sabra vanish, her children are born, and the fairy vision disappears. (See the first Part, l. 14.)

"Though the imagery and classical references in Johnson seem to shew that he copied them from some poetical composition; yet the latter could scarcely occur in a *very old* metrical romance. Perhaps he introduced them to shew his own classical learning, a fashionable accomplishment in his age.—Be that as it may, the following imagery in Wieland, who, we believe, never refers to the Roman poets, resembles the first quotation, though we do not venture to assert that it proceeds from a common origin.

No more the forest bows before the blast,
A naked wreck—but where the pillars stand
Of arch'd embow'ring roofs that shade the land,
Where nature's temple towers sublime in air,
The pomp of foliage thickens full and fair,
And clustering leaves on leaves religious gloom expand.

The earth is deck'd anew with flow'ry bloom,
Fair budding smile the garden, grove, and plain,
Charm'd echo thrills the birds' melodious strain,
And rocks are wreath'd with plants that breathe perfume.
From bubbling rills the purling currents stray
Down the green moss, and wind their silver way:
And through the night, from time to time renew'd,
The lonely bird amid the thick'ning wood
Trills to the silent moon her melancholy lay.

Canto viii. li. 50. 51.

"However accidental the preceding resemblance might be, we can scarcely entertain a doubt but that the subsequent passages in Wieland were derived from the same source as those in Johnson. The figures belong to the same piece of tapestry, but those of the German poet are unquestionably on the right side. Sir Huon and Rezia (or Amanda) are wrecked on a lonely island inhabited only by an aged hermit. After some time she finds herself in the same situation as Sabra, and experiences the same distress.

The hour was come: oppress'd with silent woe,
Amanda, lingering, near the cottage strays
'Mid fragrant shrubs that shade her secret ways,
Where op'ning flowers around profusely blow,

And breathe fresh incense on the gale of morn;
Down a small path the wanders on forlorn;
Then stops before a grot, where ivy weaves
The rich luxuriance of her clustering leaves,
While day's resplendent beams their glossy tint adorn.

Canto viii. li. 63.

"This grotto, like the wilderness in *The Seven Champions*, is a favourite haunt of the Fairy Queen, till now impervious to mankind; but Amanda

——— with gentle hand

Removes the ivy web, and enters in alone.

At once, a secret shudder gently steals
Along her frame, upon a yielding feat
She sinks, where moss and blooming roses meet.
Now only feels, through bone and marrow feels,
Thrill upon thrill swift-piercing anguish dart—
'Tis pass—sweet languor steals upon the smart.
It seems that o'er her eyes pale moon-beams glide,
Gradual in deep and deeper shadow dy'd,
Till, softly hush'd to sleep, oblivion fills her heart.

And from within her confusion gleams
Of lovely shapes; some o'er her sweep, some roll'd,
Each in the other floating, fold on fold;
Mixture of wondrous mood!—And now it seems
Before her knees three lovely angels stand:
Clear to her gaze their mystic rites expand:
And lo! a woman veil'd in rofete ray,
Holds to her lips, as dies her breath away,
A wreath of roses fresh that bud beneath her hand.

For the last time her higher-beating heart
Thrills with a short and softly-silenc'd pain.
The forms are fled away—the swoons again:
And now, without remembrance of a smart,
Wakes to soft notes, and seems afar to hear
Their low-lull'd echoes dying from the ear.
The fitter forms are vanish'd from her view;
Alone before her, robed in rofete hue,
The gracious *elixir queen* soft-smiling deigns appear.

Within her arms repos'd a new-born child:
She gives it to Amanda—then, as blown
At distance, in a *wink* away is flown;
Sweet odours breathe where late the fairy smil'd—
The dreamer opens her disenchant'd eyes.

Canto viii. li. 61.

"It is sufficient, without proceeding further, to have pointed out the most striking instance in which authors of so heterogeneous a nature, at least in respect to talents, as Johnson and Wieland, coincide. The reader, whose curiosity may lead him to compare the opening of the 14th chapter of the *Seven Champions*, with the latter part of the eighth canto in Oberon, will find some other resemblances, though of a less obvious nature.

"Poetical alchemy converts the basest ore into the richest metal; and had the fantastic creed of their superstitious ancestors been unknown to Shakspeare and Milton, we should have lost many of their most pleasing images. To discover the original mine, as in the case of Dubautas and Milton, which led us into this subject, gratifies our curiosity: and even to trace literary petty larceny in writers of an inferior class is not destitute of amusement. The few instances we have adduced,

* This word is often introduced and not happily. Almanzor *winks* his slaves to approach; and Almanzar *winks* Sir Huon away, &c. &c.

and innumerable ones might be given; are perhaps sufficient to shew, that those of the East were as little scrupulous in availing themselves of their predecessors' labours as our own countrymen.—'The Loves of Camarupa and Camalata,' though we suspect some passages interpolated by the Persian translator, is in all probability the foundation of the fictions we have already noticed in the Arabian Nights and Persian Tales. The rude and inartificial manner in which it is constructed, induces us to suppose it no modern fabrication.

"Those incidents also in Oberon, which coincide with Chaucer's January and May, seem to have come originally from the banks of the Ganges: and Einaut Oollah is much rather to be suspected of having borrowed from his countrymen than from the old bards of Europe.—We forgot to mention that Sir Floon, like Mitra Chandra, is suspected of being pursued by divine vengeance, and thrown-overboard to appease the fury of the tempest. His undertaking, however, to deprive Haroun Alrashid, the hero of the Arabian Nights, of his silver beard and four grinders, is most decidedly an accidental fiction; invented, we may conceive, by a fanciful crazy minstrel, or merry *Jongleur*, to divert some *Mahound-hating* chieftain and his martial followers when the crusade mania infected Europe.—But we are losing ourselves in the labyrinth of conjecture, without any friendly clue, any worm-eaten publication, or black-letter manuscript, to guide and direct us. We here think it advisable, therefore, to relinquish the subject."

FIELD-GARDENING, a kind of *gardening-husbandry*: the advantages of which are set forth in the following extract of a letter from Sir Henry Vavasour, bart. to Lord Carrington. This communication, published by the Board of Agriculture as an appendix to Sir John Sinclair's Observations, strongly confirms the practicability of a cottager being enabled to keep a cow by the produce of arable land only. (See COTTAGER, *Supp.*)

"The advantages that appeared to me (says Sir Henry), in cultivating land in the *Flemish* manner, or what is now called, about Fulham and that neighbourhood, the *field-gardening* husbandry, are considerable. I have for some years encouraged my cottagers in Yorkshire in this mode of managing their small garths or gardens, which are in general from one to three acres; and I have now an opportunity of stating the husbandry of a poor industrious cottager's garth. As the man can neither read nor write, these particulars have been transmitted to me from his own mouth; and, as I saw his land almost every day during the last harvest, I can vouch that this account is not far from the truth.

	Produce.	Value.	A.	R.	P.

"His flock was two cows and two pigs: one of his cows had a fummer's gait for twenty weeks with his landlord. The land was partly ploughed and partly dug with the spade, cultivated (the ploughing excepted) by the man, his wife, and a girl about twelve years of age, in their *spare* hours from their daily *hired* work, feldom a whole day off, except in harvest; made the rent in butter, besides a little used in the family. The man relates that he thinks he clears, one year with another, from the three acres, about £. 30. The daily wages his family earns, about keep them. It is very evident that this man clears from his three acres more than a farmer can possibly lay by from more than eighty acres of land in the common husbandry of the country, paying for horses, servants, &c.; and it must be obvious to every one how great the advantages must be to society by cultivating land in this manner. It would have taken more than half the quantity of his three acres in pasture for one cow at grass during half the year; whereas (excepting the fummer's gait for one of his cows, as mentioned before) his flock of two cows and two pigs is kept and carried on the whole year. The family lives well, and a handsome sum has been yearly saved to place out two sons, and supply them with clothes, washing, &c."

FILTRATION, a method of clarifying turbid liquors by mechanical straining. The term is generally applied to the passing of such liquors through filtering paper, flannel, &c. by which the feculent matter they contain is left behind. It is one of the modes of **CLARIFICATION** or **DEFECATION**. See the latter article in this Supplement.

Among the various contrivances, few appear to possess the advantage of simplicity, combined with that of affording an ample supply of a fluid so essentially necessary to the preservation of health, as pure water.—A patent has lately been granted to Mr. JAMES PEACOCK, of Finsbury-square, for a filtering machine, which is stated to be superior to any hitherto invented. It completely accomplishes the purpose of filtration, by causing the turbid fluid to ascend through a medium of fine gravel, of progressive degrees of fineness, by which means the foulest water or other fluid becomes perfectly freed from all (mixed) impurities, without any noxious mineral quality, which purine or other common filtering stones are suspected to communicate. Should, from continual use, its operation become in any degree impeded, it may be completely cleansed with the greatest facility in the short space of one minute; an advantage possessed by none of the common machines that operate by *descent*. Beside these useful properties, Mr. PEACOCK'S filtering machine does not occupy more room than a large drip-stone with its apparatus, and yields a constant and pure stream of more than 300 gallons in 24 hours.—A specimen of this machine is deposited for inspection at Guildhall, London.

The editor of the Domestic Encyclopedia, recommends a very simple and effectual apparatus, by which the purest water may be easily procured. This contrivance is calculated on the plan of the celebrated filtering machine erected at Paris, in the vicinity of the *Samaritaine*, and by means of which the foul water of the river Seine is so completely purified, as to be divested of its laxative properties. Besides, this machinery, if constructed on a large scale, is well adapted to supply the largest breweries, or dyeing works, with any quantity of pure water at a trifling expence, and is attended with very little additional trouble.

When we reflect on the method which Nature pursues in the filtration of water, we find that such waters as descend from hills, though passing through sand and rocks, are seldom perfectly pure; but that those are the most limpid, which, by ascending, ooze out near the foot of a mountain. The cause of this difference appears to be owing to the circumstance, that if the water only *descends* through sand, the finest and most weighty foreign particles gradually penetrate through the sandy strata; on the contrary, when it is forced to *rise* through sand, all such ponderous ingredients settle at the bottom; because, from their greater specific gravity, they cannot ascend to the top. The lighter particles of fluids, consequently, in both cases remain in the upper strata of the earth or sand.

From these considerations, Professor Parrot, jun. of Paris, was induced to give his filtering machine the form represented in pl. 29. fig. 1.

The principal part of the machinery consists of a square vessel, bent in the form of an inverted syphon. The curve may be circular, elliptic, or in any other direction. This vessel is filled with fine, pure sand, till nearly the height of the dotted line *x, y*, which denotes the ascent of the water to D, whence it flows into the receiver. The part marked A, B,

should always project above this line, according to the size of the filtering machine. To A, B, there is attached a woollen bag, which is open at the top, and the lower part of which touches the sand. It serves the purpose of collecting the coarsest impurities, and thus preserves the sand for a longer time from becoming foul. The bag, therefore, may occasionally be removed, and rinsed in clean water.—It is evident, that the water flows at A, through the bag into the filtre, and rises at the place marked D, which is considerably lower than the former. It affords a very agreeable sight to observe the most limpid fluid penetrating the uppermost stratum of sand, perfectly similar to that oozing from the purest natural spring.

Prof. Parrot remarks, that he procured a filtering machine made of block-tin, for ascertaining, by experiments, the purity and quality of water that may thus be obtained in a given time. It consisted of the following dimensions: the small diameter B, E, was eight Paris inches; the large of the whole machine, eleven inches; consequently the thickness of the vessel A, B, was one inch and a half;—the breadth of it, two inches and seven-eighths. The perpendicular height of the lower side, from C, to its basis, to the rim D, whence the water issues, was four inches and one-twelfth; the opposite height of the mouth A, B, eight inches and three-fourths; and the height of the sand on the side marked D, was three inches and one-sixth.

Although, in experiments of this nature, much depends on the relative size and purity of the sand, which necessarily afford different results, yet Prof. Parrot has, after repeated trials, deduced the following conclusions, which appear to be well founded.

1. That the difference of the *niveau*, or water-level, has an essential influence on the quantity of the purified water thus obtained;
2. That a prolongation of the stratum of sand does not considerably diminish the product of the filtre, but remarkably contributes to the purity of the fluid;
3. That if the water be forced to pass through the sand with increased velocity, it will be less pure than by allowing it a proper time for its passage; and,
4. That a machine of the dimensions above described, will furnish about three quarts of water in an hour, or eighteen gallons in twenty-four hours. This quantity, however, being too large in proportion to the size of the machine, it is advisable, either to lessen the difference of the water-fall; or, which is still better, to prolong the stratum of sand, in order to reduce the filtration of the water to half the quantity above stated, and to obtain it in greater purity. Thus, a filtering apparatus eighteen inches long from A to D, two inches thick, and four broad, would afford every hour six pints of very pure water. If, therefore, so small a machine, containing a very moderate stratum of sand, and requiring only a difference of two or three inches in the height of the water, furnishes a clear and pure fluid, it follows that an apparatus on a larger scale, provided with a bed of sand from five to six feet long, and admitting of a difference from twelve to eighteen inches in the fall of the water, might be usefully employed in public wells, hydraulic machines, and even in camps, for the supply of an army.

In the construction of large filtering machines, Prof. Parrot justly observes, that they should not be extended in the direction A, C, D, to a greater length than is absolutely necessary; as, in this case, they will not require any considerable difference in the fall and rise of the water: on the other hand, their breadth and thickness may be accordingly increased.—Thus, the diameter of such a machine would still more resemble that of a syphon, as is represented in the plate, at fig. 2.

This form might also be adopted for smaller machines,

Floating Baths at Hamburg.

Filtering-Machine

Fig. 1.

Fig. 2.

especially such as are designed for *travellers*, two of whom might be amply provided with pure water, and in a very short time, by a vessel of the following dimensions: from P, to Q, eight inches long; from P, to R, twelve inches high; and the whole four inches in breadth.

If the form last delineated be employed on an extensive scale, there should be a trap-door in the lowermost part marked R, so contructed that it may fit exactly, and admit no passage to the water: this aperture would serve only for the removal of the sand, when it is rendered foul by long use. In the smaller machines, intended for travelling, such a door is unnecessary, as they may be easily emptied of their contents through either of the orifices P, or Q. Instead of this addition to the latter, the upper room (which in the first of the figures is circumscribed with the letters B, F, E) might serve as a reservoir of pure water, that could either be decanted, or drawn off by means of a cock applied to the centre of the machine, marked F. We think, however, this latter arrangement, which is proposed by M. Parrot, in many respects objectionable, and therefore advise the reader to make use of the more simplified construction. Hence we shall only add, that every filtering machine ought to be provided with a cloth cover, to prevent the dust from rising with the water, without impeding its filtration.

It is needless to expatiate on the great advantages of filtering machines in the different processes of dyeing, baking, brewing, distilling, and all the domestic arts. As no particle of real nutriment can be assimilated to the human fluids, without being previously macerated and reduced by water (whether this fluid be introduced into the stomach, in the form of beer, wine, spirits, tea, &c.), it will be easily understood that *impure* water cannot fail to produce, however slowly, many dangerous, and often incurable, diseases—the source of which is seldom suspected.

FINALE, a town of Italy, on the coast of Genoa, with a strong citadel, two forts, and a castle. It was sold to the Genoese, by the emperor Charles VI. in 1713; and is 30 miles S.W. of Genoa. Long. 8. o. E. Lat. 44. 14. N.

FINALE, a town of Italy, in the Modenese. It has been often taken and retaken; and is seated on an island formed by the river Panaro, 22 miles N.E. of Modena. Long. 11. 25. E. Lat. 44. 46. N.

FINCASTLE, the chief town of Botetourt County, in Virginia, 36 miles E. of Lexington.

FINDHORN, a fishing-town in Murrayshire, at the mouth of a bay of the same name, with a tolerable harbour, 17 miles W. by N. of Elgin. Long. 3. 40. W. Lat. 57. 45. N.

FINDHORN, a river of Scotland, which rises in Invernesshire, and crossing Nairnshire and the N.W. corner of Murrayshire, forms a bay, to which it gives name, and which opens into the frith of Murray, at the town of Findhorn.

FINMARK, a part of Danish Lapland, in the government of Wardhus.

FIONDA, an ancient town of Natolia, on the gulf of Satalia, with a bishop's see, 25 miles S.W. of Satalia. Long. 31. 57. E. Lat. 36. 45. N.

FIORENZO, St. a sea-port of Corfica, on a gulf of the same name, seven miles W. of Bastia. It was taken by the English and Corsicans, from the French, in 1794. Long. 9. 20. E. Lat. 42. 35. N.

FIRE. See COMBUSTION.

FIRE-ESCAPE; a contrivance for the purpose of rescuing persons in imminent danger from fire. See *ESCAPE* in this Supplement.

In the Annual Register for 1775, an account is given of a machine for saving persons and effects from the flames. It consists, 1. Of a pole of fir, which may be of any convenient

length, being about five inches in diameter at the bottom, and at the top or smallest end, about three inches. At the distance of three feet from the top, is a mortice through the pole, to which a pulley is fixed, that is nearly of the same diameter as that part of the pole. A rope about three-fourths of an inch in diameter, and twice the length of the pole, at one end of which is a spring-hook, to pass through the handle of the basket, when used; it is put through the mortice over the pulley, and drawn tight on each side, nearly to the bottom of the pole, where it is secured till wanted. 3. A basket, which ought to be of strong wicker-work, three and a half feet long, two and a half feet wide, rounded off at the corners; and four feet deep, rounding every way at the bottom. To the top of the basket is fixed a strong iron curve, or handle, with an eye or ring in the middle: a small cord about the length of the pole, is likewise fastened to one side of the basket, near the top.—These being the principal parts, there are also several straps, &c. for securing the poles from sliding; of which the reader will find a minute account in the volume before quoted. This contrivance can be raised, and two or more persons may be taken out of the upper windows of a house, and let down safely in the street, within the space of thirty-five seconds, or little more than half a minute.

FIRE-ENGINE (*Encycl.*). Under the articles *FIRE* and *HYDROSTATICS*, various useful inventions are described for the purpose of extinguishing accidental conflagrations. In the year 1785, the silver medal and twenty guineas were conferred by the Society for the Encouragement of Arts, &c. on Mr. Furst, as a reward for his contrivance to increase the effect of engines in extinguishing fires; of which the following is a short description: From a platform rises an upright pole or mast, of such height as may be judged necessary; a gaff slides upon it in an ascending direction, and along both is conveyed the leather hose from the engine. The branch, or nose-pipe of the engine projects at the extremity of the gaff; towards which an iron frame is fixed, whence two chains are suspended: and from these hang ropes, which serve to give an horizontal direction to the branch; while other ropes that run through proper pulleys, and are thus conveyed down the mast, serve likewise to communicate a vertical motion to it. By these means, the branch or nose-pipe of the engine is conducted into the window of any room where the fire more immediately rages; and the effect of the water discharged is applied in the most efficacious manner to the extinguishing of the flames.

A patent was granted in January 1790, to Mr. Joseph Bramah, of Piccadilly, and to Mr. Thomas Dickenson, of Bedworth Clofe, in the county of Warwick, for a new improved engine on a rotative principle. The merits of this machine depend on its having two wheels or cylinders of brass, or any other metal; one of which is of a greater, and the other of a smaller diameter, in any proportion required; both are nearly of equal length, but may be increased or decreased, according to the purpose to which the machine is applied: As soon as the larger wheel is fixed, the smaller one is placed within it, and is fastened on an axis, so as to turn in a rotative direction round its centre; the smaller wheel being thus stationed, may be occasionally fixed, and the larger one moved in the same direction round the smaller one: the former of these, however, is preferable in all cases. At each end of the larger wheel there is a *flanch*, to which are screwed two plates, or caps inclosing its ends, and into which the extremities of the smaller wheel are inserted, so as to render the junction *water-tight*: through these caps passes the axis of the inner cylinder, in order to communicate motion from without.—Or the inner wheel may be applied so as to give motion, by its external end or ends, to any other engine or machine connected with it,—

These are the component parts of Messrs. Bramah's and Dickenson's patent engines; for a more particular account of which, we refer the reader to the 2d vol. of the Repertory of Arts and Manufactures, where he will find a minute account of the machinery, and the effects it is calculated to produce.

A patent was likewise granted in December 1792, to Mr. Charles Simpkin, of Oxford-street, engine-maker; for his improvements in all kinds of machines for extinguishing fire.—This invention consists in exploding or removing the valves both from that part of the cylinder where the vacuum is made by the piston or fly, and from beneath the air-vessel; and in making use of valves, by the application of certain filtering chambers, with partitions or divisions, to preserve the effect of the valves, during the use of any improper fluid. These filtering chambers are to be placed between the drawing valves, and the drain in common use, on the suction-pipe. The partitions in the chambers may be of fine wire-work, or of any other substitute, that will act as a first and second filtration in the chamber.

The design of this invention is, to render the valves more free of access, and to prevent the necessity of opening any other parts of the engine, except the chambers containing the valves; by which means the effect of the machine is increased, and consequently the fire may be more easily extinguished.

To these different contrivances we shall add the American fire-engine, of which we have given an accurate engraving. It was invented by Mr. Benjamin Dearborn, who communicated to the American Academy of Arts and Sciences, from whose Memoirs for 1794 we extract the following particulars:

Fig. 1. Plate 30, A, B, and C, D, are the edges of two planks, confined together by four bolts.—*a b*, and *c d*, are two cylindrical barrels, in each of which a piston, with a valve, is fastened to the spear *e*, and is moved up and down alternately by the motion of the arms E E. Beneath each barrel a hole is made through the plank A B, which is covered with a valve. The arms E E, are suspended on the common centre *f*: there are also arms parallel to these on the opposite side: *g g* are the ends of handles which are fastened across the ends of the arms. At *h*, a bolt goes across, from arm to arm, to which the piece *i, k*, is affixed, and on which it plays; the lower end of this piece is fastened to the top of the spear *e*.—*G, h, f*, is a standard for the purpose of supporting the arms, to which there is a correspondent one on the opposite side; both are notched into the edges of the planks, where they are secured by a bolt, which passes through them at *l*, and has a nut or fore-lock on the opposite side. H I, H I, are square braces, answering the purpose of ducts, through which the water ascends from the barrels, passing through the plank at *m*.—K L, K L, are irons in the form of a staple, in order to confine the braces: the lower ends of these irons meet, and are secured by a bolt, passing through them, and M N, *n o*, which is a piece that goes up through a mortice in the centre of the planks. This piece is square from the lower end, till it reaches the top of the braces; whence they become cylindrical to the top, the upper end being perforated sufficiently low down, in order to communicate with the braces. O, P, is an iron ring, that surrounds the tube, and has two flanks which ascend through the head, which secures on the top at *q, q*.—*r, s*, is a ferule nailed round the tube.

Fig. 2. is the same engine; the arms and standards being taken off, in order to delineate more clearly the mode of securing the braces; an object which is completely effected by a wedge driven into the mortice *a*: beneath the upper plank *l*, is a hole for admitting a passage to the bolt, which secures the standards. In this figure, a side view of the head is given, with the pipe in a perpendicular direction.

The machine is confined within a box, set on wheels, as in the common fire-engines. The whole is made of wood, excepting the spears of the pumps, and a few bolts, &c. The advantages of this machine are, that it can be made in any place where common pumps are manufactured; the interior work will not exceed one-fourth of the price of those which are constructed on the usual plan; and that they are incomparably more easy to work than the common ones; circumstances which strongly recommend the American fire-engine to the attention of the public.

On the breaking out of a fire, all constables are enjoined, by several acts of parliament, to repair to the place; to use every exertion for extinguishing the flames; and to cause people to work, &c.—By the 10 Ann, c. 14, no action shall be commenced against any person in whose house or chamber a fire shall break out accidentally: but, if such fire happen through the negligence of any servant, the latter incurs a penalty of 100*l*. to be distributed among the sufferers; and, in default of payment, he is to be imprisoned for 18 months, during which time he is to be kept to hard labour.

FIRMIN (Thomas), an eminent citizen of London, born in 1632, who distinguished himself by his public benefactions and extensive charities, as also by some opinions contrary to the received doctrine of the Trinity. The plague in 1665, the great conflagration in 1666, with the arrival of the French Protestants in 1680 and 1681, all furnished him with great opportunities of exerting his benevolent disposition. He died in 1697; and was buried in the cloisters of Christ's hospital, where his virtues are recorded in a monumental inscription.

FISH (Encycl.). For a patent method of curing fish, see the article CURING in this Supplement.

FISH RIVER, GREAT, a considerable river of Africa, which rises in the unknown interior regions, divides Caffraria from the country of the Hottentots, and falls into the Indian Ocean, in lat. 30. 30. S. The deepest parts of this river are inhabited by the Hippopotamus, and the adjacent woods by elephants, rhinoceroses, and buffaloes.

FISHER-ROW, a town near Edinburgh, on the W. side of the mouth of the Elk, which contains many handsome houses, and has some excellent villas in its vicinity.

FISHKILL, a town of the state of New York, 66 miles N. of New York. Long. 73. 48. W. Lat. 41. 31. N.

FISSATO, a sea-port of Barbary, in the province of Tripoli, 90 miles N.W. of Tripoli. Long. 12. 10. E. Lat. 33. 50. N.

FISTELLA, a fortified town of Morocco. The inhabitants carry on a great trade in fine garments. It is 125 miles N.E. of Morocco. Long. 5. 25. W. Lat. 32. 27. N.

FIVE CHURCHES, an episcopal town of Hungary, 85 miles S. of Buda. Long. 18. 13. E. Lat. 46. 5. N.

FIUME, or ST. VIT, a sea-port of Austrian Istria, with a castle. It is very populous; noted for wine, good figs, and other fruits; and the cathedral is worth observation. The harbour is formed by the river Finmara, which enters the bay of Carnero, in the gulf of Venice. It is 37 miles E. of Capo d'Istria. Long. 14. 46. E. Lat. 45. 40. N.

FIXLMILLNER (Placidus), a celebrated German astronomer, was born on the 28th of May, 1721, at Achleiten, a village in hither Austria, not far from Kremsmünster. He received the rudiments of his education in the convent of Kremsmünster, which was indebted to his uncle the abbot, Alexander Fixlmiller, for an excellent school and an observatory. Placidus conceived an early attachment to the mathematics, and took so much pleasure in delineating mathematical figures, that his mother, out of derision, called him the almanack-maker. After some stay at the above seminary, he removed to Salzburg, where he completed his course of philosophy, and obtained that faculty the degree of doctor. His taste for the mathematics, however,

M^r. Dearborn's American Fire Engine.

Flag of the British Empire.

Improved Forcing Frames.

became still stronger. His father having asked him one day, what present he should give him, he requested Wolf's Epitome of the Mathematics; which he studied with the greatest pleasure and satisfaction, during such hours as he could spare from his other avocations: but, having destined himself for the convent, he was admitted a novice at Kremsmünster, in 1737; and next year he publicly took the vows before his uncle, the abbot Alexander.

After a stay of two years in the convent, his *oheim* sent him again to Salzburg to complete his studies in jurisprudence and theology; but, at the same time, he applied with great assiduity to the mathematics, languages, history, and antiquities. He learned also to play on the harpsichord and organ; and made so much progress in music, that he composed several pieces both in the sacred and theatrical style. He disputed in some theological theses, obtained the degree of doctor in theology; and in 1745 returned to his convent, where he was consecrated to the priesthood.

About this time the *Ritter-schule* having been established at Kremsmünster, Placidus was appointed professor of canon law; a department in which he had acquired great reputation at the university. This office he held for forty years, and resigned it only a short time before his death. Almost about the same period he was appointed dean of the higher school, and soon after principal regent over the young nobility; which places he retained also till his death. He possessed great knowledge of the canon laws, and on that account was often employed in processes and other affairs relating to the convent: he was likewise inscribed *Notarius apostolicus in curia Romana*.

In the year 1760 he published a theological work, under the title of *Reipublice Sacre Origines Divine*; but he acquired far more celebrity by his astronomical labours, both as an observer and a writer. The abbot Alexander Fixlmillner, a great friend of the sciences, and particularly of the mathematics, having resolved, in the year 1747, to form an establishment in his convent for promoting the latter, first set apart a spacious apartment for the purpose of containing mathematical and philosophical instruments. This paved the way for something further; and he determined, for the improvement of his conventuals in astronomy, to erect an observatory. Among those convents which for a long time have devoted their leisure and riches to the advancement of science and the good of mankind, none has distinguished itself more than that of Kremsmünster. This very old abbey is not the seat of infidelity and indolence, but a patron of the noblest branches of science. The observatory, founded in 1748, was completed in 1758, and the superintendence of it was intrusted to Eugenius Döbler, a brother of the order.

Alexander's successor, the abbot Berthold Vogel, who long resided at Salzburg, as professor of canon law and rector of the university, being well acquainted with Fixlmillner's great knowledge, particularly in the mathematics, appointed him, in 1762, to be astronomer at Kremsmünster, with leave to retain his office as professor of canon law. He now applied with great zeal to render himself more fit for his new occupation, as he had not yet attended much to practical astronomy, and was even but little acquainted with those books from which he could obtain information on the subject. His great attachment, however, to this science, fine genius, and a desire of being useful to the institution in which he resided, and to the world, made him overcome every difficulty. The first book that fell into his hands was Lalande's *Exposition du Calcul Astronomique*, with which alone, without any oral instruction, he began to study and to make observations. This work, together with Vlacq's logarithmic tables, were for a long time his only sources and guides, till he at length obtained Lalande's

large work on astronomy. Fortunately, a carpenter, named John Illinger, born in a village belonging to the abbey, though he could neither read nor write, was able, under the direction of Fixlmillner, to construct for him very neat mural quadrants, zenith sectors, transit instruments, and pendulum clocks. Other instruments were made for him by Brander of Augsburg, and he procured achromatic telescopes from Dollond; so that by his activity the observatory at Kremsmünster soon became one of the most celebrated, and best supplied with apparatuses, in Germany. His principal assistants were Theod. Derflinger, who afterwards became his successor, and Father B. Waller.

Fixlmillner now acquired a considerable rank among astronomical writers. In 1765 he published his *Meridianus Speculae Astron. Cremsfaniensis*, in which he established the first elements of his observatory, and determined its longitude and latitude. In 1776 he published his second astronomical work, called *Decennium Astronomicum*, which contained the observations made by him at Kremsmünster from 1765 to 1775; and which is replete with important and useful information. His third work, on which he was employed towards the close of his life, and which was printed after his death, appeared in 1791. It contains a valuable collection of observations made between the years 1776 and 1791, together with a great many calculations and treatises, which still add to his celebrity in this department. Besides these, many important articles written by him are to be found in the *Journal des Savans*; Bernoulli's Epistolary Correspondence; the French *Ephemerides des Mers*; the Astronomical Almanac of Berlin; the Astronomical Ephemerides of Vienna; and the Memoirs of the Royal Academy of Sciences at Paris.

The important service rendered to the science of astronomy by Fixlmillner is well known to all astronomers. The great number of his observations of Mercury, at a time when they were rare, and difficult to be made, enabled Lalande to complete his accurate tables of that planet, for which the French astronomer publicly returned him thanks. Fixlmillner was one of the first astronomers who observed the orbit of the newly-discovered planet Uranus. He was also the first who supported Bode's conjecture, that the star 34 in the Bull, observed by Flamsteed in the year 1690, and which afterwards disappeared, was the new planet. Fixlmillner was a man of so great application and activity, that he not only made observations, but calculated them all himself, and deduced from them the necessary results. All his observations, of whatever kind, he calculated on the spot; and to avoid errors he always calculated them a second time. To uncommon industry he united great penetration and deep reflection, as is proved by the great many excellent remarks and discoveries to be found in his works. It must here be added, that this able astronomer lived in a remote part of the country, at a distance from all literary helps, and from others who pursued the same studies; that is to say, from all those things which could animate his zeal; and yet he continued, till the last day of his life, a singular instance of perseverance and attachment to his favourite study. But few men were so little subject to the imperious power of the passions. Simple in his manners, he possessed great equanimity and firmness, like the immutable laws of nature which he studied. His wide-extended celebrity did not render him proud: whatever was written or said in his praise, he endeavoured rather to conceal than to publish. His close application at length impaired his health, and brought on obstinate obstructions, which ended in a diarrhoea. He died on the 27th of August, 1791, in the 71st year of his age, the 53d of his residence in the convent, and the 46th after his entering into the priesthood.

FLADSTRAND, a sea-port of Denmark, in N. Jutland,

with a harbour defended by three forts. It is 30 miles N.N.E. of Alburg. Long. 10. 19. E. Lat. 57. 33. N.

FLADUNGEN, a town of Franconia, 40 miles N. of Wurtzburg, and 44 N.W. of Bamberg. Long. 9. 57. E. Lat. 50. 22. N.

FLAG (*Encycl.*). The happy event of the union of Great Britain and Ireland has necessarily occasioned an alteration in the national flag. See the representation of the present FLAG in plate 30. In it are combined the saltires of St. Andrew and St. Patrick, surmounted by the Cross of St. George. For the armorial ensigns displayed in the Royal Standard, see UNION in this Supplement.

FLATTERY, CAPE, on the W. coast of N. America, discovered by Captain Cook in 1778; and so named because he was disappointed at not finding a harbour. Long. 124. 57. W. Lat. 48. 25. N.

FLAVIGINI, a town of France, in the department of Côte d'Or, with a late celebrated Benedictine abbey. It is seated on a mountain, 12 miles E. of Semur, and 140 E. of Paris. Long. 4. 37. E. Lat. 47. 26. N.

FLECHE, a town of France, in the department of Sarthe. Here is the noblest college in France, built in 1603, by Henry IV., and in the chapel are deposited his heart and that of his queen in gold boxes. It is seated on the river Loire, 22 miles N. of Angers. Long. 0. 3. W. Lat. 47. 39. N.

FLEECE-HOSIERY, a very useful kind of manufacture, in which fine fleeces of wool are interwoven into a cotton piece of the common stocking texture. The following is the specification of the Patent granted to Mr. Holland, of Broad-street, Bloomsbury, in the county of Middlesex, for a method of making stockings, socks, waistcoats, and other clothing, for persons afflicted with complaints requiring warmth, and for common use in cold climates, and for making false or downy calves in stockings. It is dated September 22, 1788.

He describes the nature of his invention in these words: "Having in the common stocking-frame, twisted silk, cotton yarn, flaxen or hempen thread, worsted or woollen yarn, or any such-like twisted or spun materials, begin the work in the common manner of manufacturing hosiery, and having worked one or more course or courses in the common way, begin to add a coating, thus: draw the frame over the arch, and then hang wool or Jersey, raw or unspun, upon the beards of the needles, and slide the same off their beards upon their stems, till it comes exactly under the ribs of the sinkers; then sink the jacks and sinkers, and bring forward the frame, till the wool or Jersey is drawn under the beards of the needles, and, having done this, draw the frame over the arch, and place a thread of spun materials upon the needles (under the ribs of the sinkers), and proceed in finishing the course in the usual way of manufacturing hosiery with spun materials. Any thing manufactured in this way has, on the one side, the appearance of common hosiery, and on the other side the appearance of raw wool. The raw or unspun materials may be worked in with every course, or with every second, third, or other course or courses, in quantity proportioned to the warmth and thickness required. The above-mentioned raw or unspun materials may be fixed also thus: having drawn the frame over the arch, hang them upon the beards of the needles, slide them off the beards upon their stems, and without sinking the jacks and sinkers, draw the frame off the arch, and bring the raw or unspun materials forward under the beards of the needles; then draw the frame over the arch, and proceed in finishing the course, as before directed. The said raw or unspun materials may be fixed likewise thus: hang them upon the beards of the needles, without having the frame over the arch, and slide them off their beards upon their stems; then bring forward the frame till the raw or unspun materials

are drawn under the beards of the needles, and, having done this, draw the frame over the arch, and proceed in finishing the course as before directed. Hosiery may be coated by any of these methods, not only with wool and Jersey, but also with silk, cotton, flax, hemp, hair, or other things of the like nature, raw or unspun, but the method first described fixes them most firmly. The common stocking-frame is mentioned above, but any other frame, upon a similar principle, may answer the purpose. The method of making the false or downy calves in stockings, is by working raw or unspun wool, or Jersey, or any other raw or unspun materials, into the calves of stockings, in the different methods before described, and to any required form or thickness." The latter use to which this invention is applied, we may be allowed to say, is somewhat ludicrous.

FLEET, a river in Kircudbrightshire, which winds through a beautiful valley, and enters Wigton Bay, at Gatehouse. On the W. side of the river are the vestiges of a camp, a druidical circle, and a vitrified fort.

FLENDENBURG, a town of Denmark, capital of Sleswick, with a strong citadel. It has a harbour in the Baltic Sea, and is a place of considerable commerce, 15 miles N.W. of Sleswick. Long. 9. 47. E. Lat. 54. 50. N.

FLEURANCE, a town of France, in the department of Gers, 13 miles N. of Auch. Long. 0. 36. E. Lat. 43. 51. N.

FLEURUS, a village of the Netherlands, in the province of Namur, remarkable for a victory gained by the French, over the allies, in 1690; and here, in June 1794, the Austrians were defeated in a general attack of the French posts. It is six miles N.E. of Charleroy.

FLEURY, a town of France, in the department of Saône and Loire, 30 miles N. of Chalons. Long. 4. 50. E. Lat. 47. 13. N.

FLEXIBLE STONES. In the Philosophical Magazine we find a communication from Professor M. A. Pictet, of Geneva, on Flexible Stones, addressed to the editor, Mr. Tulloch. Alluding to another writer's description of the *elastic quartz*, or *flexible sand-stone*, from Brazil, he wonders that the author did not mention a similar phenomenon which has been observed in another stony substance, commonly as inflexible as any siliceous aggregate, but thoroughly different in point of chemical composition—"I mean," says he, "the table of *elastic marble*, which is shewn at Rome as a great curiosity. A friend of mine, M. Fleuriat de Bellevue, from La Rochelle, who had seen it, guessed at the cause of its flexibility, and went so far as to render, by a particular process, any given specimen of Carrara marble as evidently flexible as the table in question. He pursued at Geneva the series of experiments which led him to that discovery, and read to our Society of Physics and Natural History an account of the whole, which has been since published in *La Metherie's Journal de Physique*. The following are the leading facts:

"That species of marble consists, as you well know, in a confused aggregation of small irregular crystals interwoven in all possible directions, and adhering to one another by a certain degree of cohesive force. He thought that if he could, by any process, destroy that adherence, without altering much the solidity of the crystals themselves, he might thus obtain a loose, but entire, stony aggregate, which would become flexible on account of the relative mobility of the integrant crystals, but keep its solidity and preserve its form in consequence of their being deeply implicated and interwoven among themselves.

"According to that theory, he undertook a series of experiments by exposing slips of marble to the action of fire in sand-baths of regularly graduated and well ascertained temperatures: he thus found a point where the adhesion of the crystals was loosened, without any material alteration in their hard-

ness. He gave to his friends some specimens of *Cariara* marble thus rendered flexible. I have one of them in my possession here in London, which may be seen by any person who should yet entertain any doubts as to the possibility of the fact.

"Now, a volcanic fire may have acted on a large mass of marble nearly as my friend's furnace has done on his small specimens; and this explanation of the natural phenomenon I consider as being as near to truth as most of our conjectures on similar subjects can be."

FLIE, or VLIeland, an island on the coast of Holland, at the middle of the entrance of the *Zuyder-Zee*.

FLIX, a town of Spain, in Catalonia, strong both by art and nature. It is built on a peninsula, in the river *Ebro*, where it makes an elbow, which serves the town instead of a ditch, and may be conducted quite round it. The side where the river does not pass, is covered by mountains, and defended by a castle on an eminence; and near it is a waterfall. It is 20 miles S. of *Lerida*. Long. o. 26. E. Lat. 41. 15. N.

FLOATING BATHS. As the erection of public baths has, from the remotest ages, been considered an object worthy of national attention, and private solicitude, we have selected the following article from the *Domestic Encyclopedia*: The floating baths at *Hamburg* are an establishment which owes its origin to the enlightened members of the "Society for the encouragement of Arts and Useful Trades," founded in that city, in the year 1765. These baths were projected by *Dr. Moldenhawer*, physician at *Hamburg*, and erected by public subscription, on a small lake of fresh water, called the *Alster*. *M. Arens*, an eminent architect of the same city, delineated the plan of the building, which, we are informed, is an improvement on similar baths established in the principal towns of the French republic.

Although we have not had an opportunity of comparing the internal construction of the *Hamburg* baths, with those floating on the river *Thames*, near *Westminster-bridge*, yet we have reason to believe that they are essentially different from any other existing in this country. Induced by this consideration, and convinced of the intrinsic advantages which the former possess, independent of their beautiful external appearance, we have caused accurate representations to be given in Plate 29, of which the following is an explanation:

Fig. 1, *A*, The elevation of the longitudinal front of the Floating Bath, with its ornamental entrance; of the surrounding gallery, and the tents expanded over the bathing machines, and covered with fail-cloth, which had been four times varnished. The wooden roof is also covered with strong fail-cloth, which had been repeatedly coated with tar. The whole vessel is 80 feet in length, and 40 in breadth.

B, Elevation of the transverse side of the Floating Bath, with its glass doors and windows, through the former of which the corridor, and through the latter the cabins on each side receive their light.

C, Section of the Building: namely, *a, b*, of the Bathing Machines, and *c, c*, of the chambers for undressing and dressing. On each longitudinal side of the vessel, there are (as appears on inspecting Plate 29) six of these chambers, which may be easily opened from within; and on each transverse side are two lateral cabins, partly furnished, and partly designed for store-rooms, to hold various implements.

The corridor, extending from one side-door to the other, within the centre of the building (see fig. 2, *B, f*), is seven feet and a half wide; and on each side are the bathing machines and chambers.

These chambers for undressing and dressing, which are provided with sky-lights, and marked *C*, are seven feet and a half in length, and four feet wide. They are anti-chambers to the

bathing machines *a, b*, and each of the former contains the most necessary articles of furniture, such as a table, chair, looking-glass, cork-couch (for supporting the feet till they are dried, after coming from the bath), pegs for suspending clothes, a boot-jack, &c.

The bathing machines *a, b*, below the surface of the water, consist of four sides, made of laths two inches thick, through which it flows, and they are provided with a solid wooden floor, secured by iron staples. These machines are six feet broad and seven long, so that the whole body may move in them without constraint.

Their construction renders them moveable, so that they may be raised or lowered at pleasure and with little trouble, as appears from the machine *b*; while the impurities settled at the bottom may be easily removed. At the side of the steps (see fig. 2, *h*), which extend to the bottom of the bathing machine, the latter is provided with a balluster (fig. 2, *i*), adjacent to which is placed a table and chair. The bathing machines are adapted to different depths of water, so that every individual may regulate them at 2½, 3, 3½, or 4 feet in depth, and these proportions are marked within the chamber. Above each machine are suspended two strings, one of which is connected with a bell fixed in the corridor, for calling the waiter: by means of the other, the bathing person may exclude the current of air circulating between the bottom of the floating vessel and the surface of the water, as there is a wooden board which slides down for that purpose.

Fig. 2, *A*, Represents the construction of the floating vessel, which serves for the foundation of the building. It consists of strong double fir-beams, connected with each other by iron bolts and staples.

B, Represents the ground-plan of one half of the floating vessel; *a*, the entrance; *b*, a room on the opposite side for the waiter, who is appointed to receive and deliver the admission tickets, &c.; *c*, the lateral cabins; *d*, the undressing chambers; *e*, the bathing machines; *f*, the corridor; *g*, the surrounding gallery; *h*, the staircases leading into the water; *i*, the ballusters at the bathing machines: all these parts have already been described.

In his *View of the Russian Empire*, the *Rev. W. Tooke*, who resided many years in that country, says, "It is not to be doubted that the Russians owe their longevity, their robust state of health, their little disposition to certain mortal diseases, and their happy and cheerful temper, mostly to these baths; though climate, aliment, and habits of living, likewise contribute their share.—The great Lord-chancellor *Bacon*, and other sagacious observers of nature and of mankind, have lamented, and certainly not without cause, that this bathing has fallen into disuse among the modern nations of Europe, and justly with the practice back again in all our towns and villages. In fact, when we consider that the old physicians so early introduced into their practice this remedy of Nature's own invention, and employed it with such great success; when we recollect that *Rome*, for five hundred years together, had no physicians, but only baths, and that to this day a multitude of nations cure almost all their maladies merely by baths; we cannot avoid regarding the dismission of them as the epocha of a grand revolution which has been wrought in the physical state of the human race, in our quarter of the world.

"The natural perspiration, the most important of all excretions, must naturally go on better in a body constantly kept soft by bathing. A great number of impurities which privily lay in us, the train to tedious and dangerous distempers, are timely removed, ere they poison the blood and the juices.—All exanthematic diseases are abated by bathing, consequently

then the small-pox; and if this dreadful disorder be actually less fatal in Russia than in other countries, this phenomenon need not be attributed to any other cause than the vapour-baths."

FLODDON, a village in Northumberland, five miles N. of Wooler. Near this place a bloody battle was fought between the English and Scots in 1513, in which James IV of Scotland was killed, with the principal of his nobility, and 10,000 men.

FLORAC, a town of France, in the department of Lozere, 13 miles S. of Mende, and 23 N.W. of Alais. Long. 3. 30. E. Lat. 44. 18. N.

FLORENT (Sr.), a town of France, in the department of Maine and Loire, with a late rich Benedictine abbey; seated on the Loire, 20 miles W.S.W. of Angers. Long. 0. 56. W. Lat. 47. 24. N.

FLORENTIN (Sr.), a town of France, in the department of Yonne, at the confluence of the Armanche and Armançon, 15 miles N.E. of Auxerre, and 80 S.E. of Paris. Long. 3. 55. E. Lat. 48. 1. N.

FLORENTINO, one of the three provinces of Tuscany; bounded on the W. by the republic of Lucca and the Modenese, on the N. by the Apennines, on the E. by the duchy of Urbino, and on the S. by the Siennese. It is well watered, and very fertile. Florence is the capital.

FLORES, a fertile island, one of the Azores, so called from the abundance of flowers found upon it. Long. 31. 0. W. Lat. 39. 34. N.

FLOTZ, a town of Upper Saxony, in the principality of Anhalt Zerbst, six miles N.W. of Zerbst.

FLOTZ, a town of Walachia, seated on the Geniſſa, near its influx into the Danube.

FLOUR (Sr.), an episcopal town of France, in the department of Cantal. Good knives are made here, and its fairs are famous for the sales of mules and rye. It is seated on a mountain, 45 miles S. of Clermont and 250 of Paris. Long. 3. 11. E. Lat. 45. 2. N.

Flour (Encycl.). In 1795, when the extreme dearth of bread made all persons anxiously attend to every circumstance which contributed to enhance its price, a *Friendly Society* at Rothley, in Leicestershire, determined to employ 50*l*. of their capital in purchasing corn, and to dispose of the flour obtained from it at a low price. Their chief object was to supply the members of the society with flour at prime cost. They purposed also to sell it to their neighbours at a price, which, though considerably lower than that at which the article was retailed by the neighbouring millers and hucksters, might give them legal interest for their 50*l*. and indemnify them for contingent expences and losses. In a short time, however, this distinction between members and other persons was thought invidious; and flour was sold by the stone to all who applied, on such terms as would barely reimburse the price of the corn and the expences, and afford interest for the 50*l*.

It was their resolution to sell for ready money only; and they fixed on a part of every Monday, when two of their members were to attend at their club-room, and supply such purchasers as should apply there. They bought a quantity of corn with the assistance of a respectable farmer; and found that they could sell the flour for at least sixpence a stone (of 14*lb*). less than was charged for flour, apparently of the same quality, by the neighbouring dealers. The saving to the purchasers was about 20*l*. per cent. Flour continued to be sold to the amount of 10*l*. or 12*l*. every week, until after some months had elapsed, when the millers lowered the prices, and the sales decreased. From that time to the present, from 4*l*. to 7*l*. has been the amount of the weekly sum received at the sales.

When the plan of the society was first set on foot, they sold much more barley flour than wheat flour; but, as corn became cheaper, the poor returned by degrees to the use of wheat, to which most of them had been accustomed; and now the quantity of wheat flour disposed of is three-fourths or four-fifths of the whole quantity sold. The wheat is ground into a sort of flour called "thirds," without any of the finer part of the flour being taken from it; and thus all the nutritious qualities of the grain are preserved. The bread made of this flour is very wholesome and palatable, and not so brown as that which is frequently eaten in farmers' houses. There is a very ready sale for the bran, which, in order to make the flour of the requisite quality, is separated at the mill from the gross produce of the wheat. The miller is not paid for grinding by an allowance of toll, but in money; which is found to be by far the most eligible method of satisfying his demands. For some time flour has been sold on two days of the week, for the better accommodation of the poor.

The foregoing plan has effectually answered the purpose of keeping the price of flour as low as that of corn would admit; and, in some degree, of improving the quality of the flour sold in the neighbourhood, by affording the poor a certainty of buying it, in its purest state, of the friendly society.

Every thing that contributes to supply the poor with genuine flour, at a fair price, is of very great importance; otherwise the greater part of the poor will be compelled to apply to the mealman, the huckster, or the baker, for the chief article of their food; and, in general, to pay from 15*l*. to 25*l*. per cent., probably upon an average 20*l*. per cent. more than the original cost of the flour. The mode adopted at Rothley, is such as would be imitable in almost every part of the kingdom; and it has the merit of putting into the hands of the suffering individuals, their own remedy against the monopoly of the millers.—It is to be observed, that the power of purchasing corn is by no means so clear and decisive a benefit to the poor, as that of purchasing flour at prime cost.

The benefit of the plan adopted at Rothley is so evident, the mode of process so simple, and the amount of expence so easily ascertained, that arguments in its favour are unnecessary. It may however be of use to suggest some cautions, grounded on circumstances which have happened at Rothley, as to the mode of executing such a plan.—1*st*. It is material that the price should be such as will allow at least in some degree for the risk of the speculation. An unexpected loss has happened at Rothley by a sudden fall in the price of wheat, and by the destruction of some corn in a windmill.—2*dy*. The society should be prepared for the effects of a competition, on the part of the neighbouring millers. A reduction in their price of flour, bringing it nearly if not quite to a level with the price of the society, will assuredly take place. This, though in fact one of the very beneficial consequences of such a measure, will lessen the custom of the society for a time, while it affords incontrovertible evidence of the utility of the plan, and of the service which it has done the neighbourhood.—3*dy*. The accounts, in this and in all other matters of buying and selling, should be very correctly kept. If this is not done, every such undertaking will in the end be a losing trade.—4*thly*. It is essential, that the resolution of selling for ready money only, should be punctiliously adhered to: otherwise the society will hold out a most pernicious temptation to the poor to run in debt, and will involve itself in the risk of being induced to give them still more credit, in order to obtain payment of their exiling debts. Besides, where a society is numerous, and consists of manufacturers, artisans, and day-labourers, there is no possibility of ascertaining the line to be

adhered to, when the rule has been once broken. Each individual will vote that his neighbour should have the same, or a greater indulgence than the person who preceded him. Thus all the distinctions, usually made by private shopkeepers in giving credit, will be disregarded, and ruin must ensue. In cases of private trade, credit is given for the purpose of obtaining custom: but when public benefit is the sole object of a society, they may disregard the little arts of the shopkeeper; and proceed inflexibly upon that plan, which is most beneficial to the individual; and to the public.

Similar modes of procuring a regular supply of flour, at a moderate price, have been adopted at Quorndon, Sibley, Mountferrill, and some other places in Leicestershire; recommended by the same benefits, as those attending the execution of the plan at Rothley.

An account of a mode adopted in the parish of Hadham, in the county of Hertford, for supplying the poor with flour of the best quality, and at a reasonable rate, is given by the Rev. Dr. Hamilton, in the Reports of the Society for bettering the Condition of the Poor.

"During the whole of the autumn of 1797," says Dr. Hamilton, "complaints were made, throughout the parish and neighbourhood of Hadham, of the great difference in the proportional price of wheat at the markets, and of flour as sold at the mill, or in the shops. I was very sensible of the grounds for discontent; both in the sellers of wheat, and the purchasers of flour; and, as a remedy for the grievance, I determined to procure, from time to time, a sufficient quantity of good wheat from the market (having prevailed on a very respectable miller in the neighbourhood, to undertake to grind for me as much as I should require), by which means I might be able to supply the poor of the whole parish with good flour, and at a reasonable price. This has been done for these last three months, and is still in practice, giving very great satisfaction to the poor, who are the purchasers.—My first purchase was as follows:

	£.	s.	d.
110 bushels of wheat	30	4	0
Grinding, dressing, and bringing home	1	12	3
Total	31	16	3

PRODUCE.

340 pecks and 3 lb. of flour, at 1s. 9d. per peck	30	2	5
18 strikes of pollard, at 1s. 6d. per strike	1	7	0
2 quarters and 4 bushels of bran, at 8s. per quarter	1	0	0
	32	9	5
Prime cost	31	16	3
Profit	0	13	2

"This accommodation to the poor has been effected without any expense, except the advance of 40l. and with very little

trouble. At the parish work-house there is a large vacant room, where the sacks of flour are deposited, as they come from the mill; and, twice in the week, a servant attends two hours, with the master of the work-house, in the flour chamber; and the poor are, with great convenience, thus served with the best wheat flour, and with full measure."

Dr. Hamilton's agent sold, during the fortnight, about 40 sacks, at 1s. a bushel under the shop price; the saving upon which, to the poor who are purchasers, amounts to 5l. per week: he is not at present able to tell exactly what the profit or loss is; but he believes it is not much either way. Wheat too has been rising almost every week for some time; and probably he must raise his price one penny in the peck. His calculation, as to the load of wheat which he has just bought, is as follows:

	£.	s.	d.
Price of the load	12	0	0
Grinding, ditto	0	8	0
Carriage from the mill	0	3	9
	12	11	9

PRODUCE.

124 pecks of flour, at 1s. 10d.	11	7	4
8 strikes of pollard, at 1s. 6d.	0	12	0
1 quarter of bran, at 8s.	0	8	0
	12	7	4
Loss	0	4	5
	12	11	9

OBSERVATIONS.

By these means the poor are enabled to purchase their flour, with a saving of at least 4d. in every peck, exclusive of the benefit of having it of the best sort, and full measure; which, at 5l. per week (the gain on twenty sacks), amounts to 260l. per ann.; being two-thirds of the whole poor's rate of the parish of Hadham. This plan gives such general satisfaction, that it will probably be soon adopted in the adjoining parishes; the poor of which have been, in some instances, supplied from the flock. It is also beneficial to the other classes of life, as well as to the poor: the miller, upon this flour being sold, at first reduced his price from 8s. 8d. to 8s. 4d.; and he has not raised it for the last two months, though the price of wheat considerably advanced during that period.

Every thing that can be done, to enable the poor to procure the necessities of life, at a moderate rate, of full measure, and of good quality, is of the utmost importance. It has been the misfortune of this country, that, in every article of food, the profits of the speculator interfere between the growth and the consumption; and, in some instances, increase the price to nearly double. If the farmer would supply his labourer with flour, potatoes, bacon, and cheese, at prime cost, he would enable him to maintain his family much better, and at less ex-

* It is said in confirmation of Dr. Hamilton's observation, that in the fourth division of Easington ward, in the county of Durham, on a strict inspection of weights and scales by order of the magistrates, the deficiency discovered in the smaller shops was such (as appears by the statement of the chief constable who made the examination) as had occasioned a loss to the poor of that district, though small and by no means populous, amounting to not less than 500l. a-year.

+ It would be a very desirable thing that the poor should be able to supply themselves with beer of their own brewing, without being obliged always to recur to the alehouse. We are aware of the disadvantage in brewing small quantities; but that might be compensated for by great advantages, and by the superior flavour of beer *brewed and drank at home*.—The following receipt is according to the proportions used in the House of Industry, at Shrewsbury. Take half a bushel of malt, and four pounds of treacle, and three quarters of a pound of hops; this will make twenty-five gallons of beer; the cost of which (supposing the

pence, and thereby prevent the increase of the poor's-rate: he would attach him to his service, and put an end to the old complaint of the "*rambling and unsettled disposition of the poor*:" he would also keep down the price of labour; which is necessarily increased on account of the disadvantageous situation in which the labourer is placed as to the purchase of every necessary of life. In short, the farmer would do his labourer much good, and himself more.

FLOWERS (*Encycl.*). Though no parts of plants are more generally known than their flowers, yet the definitions given by different authors of this word are very various, and necessary to be explained in order to the understanding of their works. Jungius defines it to be the most tender part of a plant, remarkable for its colour or form, or for both, and cohering with the fruit. But this author himself acknowledges his definition to be too limited, as there are several plants whose flowers are produced remote from their fruit. Mr. Ray says, the flowers cohere for the most part with the rudiments of the fruit: which is likewise a phraseology too inaccurate to be admitted in definitions. Tournefort defines the flower to be a part of a plant very often remarkable for its peculiar colours, for the most part adhering to the young fruit, to which it seems to afford the first nourishment, in order to explicate its most tender parts: but this is still a more indeterminate definition than the former. Pontederá defines a flower to be a part of a plant, unlike the rest in form and nature. If the flower has a tube, it adheres to, or is fixed very near, the embryo, to the use of which it is subservient; but if the flower has no tube, then its base does not adhere to the embryo. This definition is scarce intelligible, except to expert botanists. Jussieu defines a flower to be composed of chives and a pistillum, and to be of use in the generation of the plant: but this definition is too imperfect, as there are many plants in which the pistillum is found at a great distance from the chives, many flowers which have no pistillum, and many which have no chives. Vaillant has been happier in his definition. He says, that flowers are the organs which constitute the sexes of plants, which are sometimes found naked, and without any covering; and that the petals which most of them have are no way essential to their use, but serve, and are intended, merely as covers for them: but yet, as these coats or coverings are the most conspicuous and most beautiful parts of the flowers, these are to be called *flowers*, be they of whatever form or structure or colour; and whether they contain the organs of both sexes in each individual, or only of one, or even but of some part of one, provided they are not of the same figure and colour with the leaves of the plant. The shortest and most express definition, however, seems to be that of Martin; which is, that flowers are the organs of generation of both sexes, adhering to a common placenta, together with their common covering; or of either sex separately, with its proper coverings if it have any.

The parts of flowers have been already described under **BOTANY**, p. 33, yet we apprehend the following general remarks made by eminent botanists, on *growth, enlargement, colours, and duplication of flowers*, particularly those of Dr. Darwin, will be very acceptable.

1. It is an established fact, that flowers as well as fruits grow larger in the shade, and ripen and decay soonest when exposed to the sun. Hence, likewise, the foliage or buds of plants requires more moisture for its vigorous growth than their flowers, or organs of fructification. Further, observes

Dr. DARWIN, the frequent rains of our climate, are apt not only to wash off the farina from the bursting anthers, and thus to prevent the impregnation of the pistil, but also to delay the ripening of the fruit or seeds, from the want of a due evaporation of their perishable matter, as well as from the deficiency of solar light in the cloudy seasons. In another place of his admirable *Phytologia*, this philosopher remarks that, as a superfluous supply of water is more friendly to the growth of leaf-buds, than to the generation of flower-buds, the production of seeds may be forwarded by supplying their roots with less water than usual. But when the blossoms appear, an addition of water promotes their growth, by affording nourishment, which should again be lessened, when the fruit has acquired its full size, both to promote its maturity and improve its flavour; as the saccharine matter and essential oil will thus be in a less diluted state.—Although the fruit may become sweeter and larger, when the green as well as the floral leaves continue on the tree, yet the corols, with the stamens, stigmas, and nectaries (the succeeding fruit not considered), suffer, in the opinion of Dr. DARWIN, no injury when both kinds of leaves are removed, as by the depredations of insects. Nay, some florists assert, that the flowers thus become stronger, producing no bulbs, as is the case with tulips and hyacinths.

2. The variegated colours of the petals of flowers are so beautiful, and afford such delight to the eye of the contemplative naturalist, as to deserve some investigation. It is probable that *varieties* in the colours of single flowers raised from seeds, may be generally obtained by sowing those which already possess different shades, contiguous to others of the same species; or, by bending the flowers of one colour, and shaking the anther-dust over those of another. Thus Dr. DARWIN supposes the beds of the corn blue-bottle, *centaurea cyonis*, acquire those beautiful shades of blue, purple, and white. As some animals change their natural colours; when transplanted in different situations of soil, a similar effect may be produced by sowing flowers in fastidious composts, which considerably differ from each other with respect to vegetable nutriment, and perhaps also in their colour. Experiments on this subject, as well as on the variegation of the leaves of shrubs and trees, are however wanting to confirm this conjecture; though the latter probably originates from soil or situation, and may be communicated by grafting.—The origin of *new* colours in flowers, and of variegated foliage, is imagined to arise from the want of nourishment of the soil on which they grow, compared to that assigned to them by Nature; or from a defect of moisture and of heat; a supposition countenanced by the dwarfish size of such plants, in general, and especially by the reduced stature of tulips, when their petals acquire various colours.

The immediate cause of the various colours presented by some flowers, such as poppies, has not hitherto been distinctly ascertained; but Dr. DARWIN conjectures that, as they are not variable by the obliquity with which they are seen, like those of mother-pearl, card-fish, &c. they do not depend on the thinness of their pellicle, and may, therefore, arise from the greater facility which some parts of vegetables, more than others, possess in parting with their oxygen (which see) when exposed to the sun's light; for all flowers are more or less blanched before they first open.

3. The origin of *double flowers* is believed to result from the luxuriant growth of the plant, in consequence of excessive nou-

value of the grains to be only equal to the expence of fuel) would be 2d. a gallon, where the materials were purchased to the best advantage; and, when bought at the retail shop, about 3d. The receipt was tried and found to answer; the beer being very good. It was fit for use in a fortnight; but it is not calculated for keeping, particularly in warm weather.

rifulness, moisture, and warmth: they arise from the increase of some parts of the flower, and the consequent exclusion of others. As they produce a greater blaze of colour in a small space, and continue in bloom for some weeks longer than single flowers, the method of producing them from seeds is a matter of importance. Botanists very properly term such multiplied flowers *vegetable monsters*, because they possess no stamens or pistils, and therefore can produce no seeds.—Nevertheless, they are frequently raised immediately from seeds; because flowers cultivated with more manure, moisture, and warmth than is congenial to them, not only grow larger and more vigorously, but likewise shew a tendency to become double, by having one or two supernumerary pistils in each flower, such as the stock July flower, cheiranthus, and anemone. It is still more remarkable that this duplicature is communicated to those individual blossoms: hence florists tie a thread round such flowers, to mark them, and to collect their seeds separately, from which double or full flowers are said to be uniformly produced, if they be cultivated with additional manure, moisture, and warmth, as has been already observed.—There subsists a curious analogy, concludes Dr. DARWIN, between these vegetable monsters and those of the animal world; for a duplicature of limbs frequently attends the latter, as chickens and turkeys with four legs and four wings, and calves with two heads. In mules, also, the most important organs become deficient, so that they cannot propagate their species; exactly analogous to these full flowers which, from the same cause, produce no seed. With respect to botanic systems, it may be observed from these vegetables of exuberant growth, that the stamens and pistils are less liable to change than the corols and nectaries; consequently, that they are more proper parts for arranging plants into classes; and that on this idea LAMÆUS constructed his unrivalled system. Lastly, the calyx, or perianth, being seldom found in a double or multiplied state, is the next part of a flower that is liable to the least changes; and may, therefore, on accurate inspection, serve to detect the genera of double flowers.

FOCHABERS, a town in Banffshire, seated in a plain, near the river Spey. Here is Gordon castle, the princely mansion of the Duke of Gordon; and in the town, many girls are employed in spinning, and the manufacture of sewing thread, under the patronage of the duchess. It is 48 miles N.W. of Aberdeen.

FO-CHAN, a village of China, in the province of Quang-tong. It is called a village, because it has no walls nor a preceding governor, although it has a great trade, and contains more houses and inhabitants than Canton. It is reckoned to be nine miles in circumference, and to contain 1,000,000 inhabitants. It is 12 miles from Canton.

FOCHIA NOVA, a sea-port of Natolia, with a good harbour, and a castle. The Venetians beat the Turkish fleet, near this place, in 1650. It is seated on the gulf of Sanderley, at the mouth of the Hermus, 28 miles N.W. of Smyrna. Long. 26. 39. E. Lat. 38. 44. N.

FODWAR, a town of Hungary, seated on the Danube, opposite Colocz: Long. 19. 16. E. Lat. 46. 39. N.

FOGARAS, a town and castle of Transylvania, on the river Alauta, 30 miles N.E. of Hermanstadt. Long. 25. 25. E. Lat. 46. 30. N.

FOGGIA, a town of Naples in Capitanata, seated near the Cerbero, 20 miles S.W. of Manfredonia.

FOGLIA, a river of Italy, which rises on the confines of Tuscany, crosses the duchy of Urbino, and falls into the gulf of Venice, and Pesaro.

FOGLISSO, a town of Piedmont, five miles N.W. of Chivas, and 13 W. of Cressentino.

FOHR, or **FORA**, an island of Denmark, about 12 miles in

circumference, near the coast of Sleswick. Long. 3. 31. E. Lat. 54. 44. N.

FOIA, an ancient town of Natolia, on the gulf of Smyrna, with a good harbour and a strong castle, 30 miles N. of Smyrna.

FOIX, a town of France, in the department of Arrarie. Here is a manufacture of coarse woollen cloths, and some copper-mills, which metal is a considerable object of commerce. It is seated on the Arriege, at the foot of the Pyrennees, eight miles S. of Paniers. Long. 1. 32. E. Lat. 43. 0. N.

FOLIGNI, an episcopal and trading town of Italy, in the duchy of Umbria; remarkable for its sweetmeats, paper-mills, silk manufactures, and fairs. It is seated on the declivity of a mountain, near a fertile plain, 69 miles N. of Rome. Long. 12. 24. E. Lat. 42. 48. N.

FONDI, an episcopal town of Naples, in Terra di Lavoro, seated on a fertile plain, but in a bad air, near a lake of its own name, 42 miles N.W. of Capua, and 50 S.E. of Rome. Long. 13. 24. E. Lat. 41. 22. N.

FONG-TSIANG-FOU, a city of China, in the province of Chen-fi. Its district contains eight cities of the second and third class. It is 495 miles S.W. of Peking.

FONS, a town of France, in the department of Lot, five miles N.W. of Figeac. Long. 1. 55. E. Lat. 44. 37. N.

FONTAINE L'ÉVEQUE, a town of France, in the department of the North, near the river Sambre, three miles W. of Charleroy. Long. 4. 18. E. Lat. 50. 23. N.

FONTANETTO, a town of Piedmont, seven miles E. of Cressentino.

FONTELLO, a town of Portugal, in Beira, six miles N.E. of Lamego. Long. 7. 27. W. Lat. 51. 36. N.

FONTENAI-LE-COMTE, a town of France, in the department of Vendee. It has a woollen manufacture, and its fair is famous for cattle, particularly for mules, on which last account it is resorted to by the Spaniards. It is seated on the Vendee, near the bay of Biscay, 25 miles N.E. of Rochelle. Long. 0. 55. W. Lat. 46. 30. N.

FONTEVRAULT, a town of France, in the department of Maine and Loire. Here was a famous abbey, founded by Robert d'Arbriflé, in 1100. It was the chief of a religious order, which, by a singular whim of the founder, consisted of both sexes, and the general of which was a woman. Queen Bertrade, so famous in history, was among the first nuns that entered this abbey. It is nine miles S.E. of Saumur, and 160 S.W. of Paris. Long. 0. 0. Lat. 47. 9. N.

FONTICULUS, or **FONTANELLA**, in surgery, an issue, seton, or small ulcer, made in various parts of the body, in order to cause a discharge.

FORCALQUIER, an ancient town of France, in the department of the Lower Alps, seated on a hill, by the river Lave, 20 miles N.E. of Aix. Long. 5. 48. E. Lat. 43. 58. N.

FORCHEIM, a strong town of Franconia, in the bishopric of Bamberg, with a fine arsenal. It surrendered to the French in 1796, but the Austrians compelled them to abandon it soon afterward. It is seated at the confluence of the Wifent and Rednitz, 16 miles S.E. of Bamberg. Long. 11. 2. E. Lat. 49. 44. N.

FORCING (*Encycl.*). The following description of newly-invented moveable forcing-frames for plants, &c. by Bénard, a member of the Agricultural Society of Seine and Oise, was read at a public sitting of that Society.

"It is uncertain," says the author, "whether the ancients were acquainted with any artificial means of accelerating vegetation; countries inhabited by the Greeks and Romans not compelling them to seek the assistance of art to supply any deficiency in the liberality of nature.

"With regard to our own ancestors, it appears that the objects of industry being then equally rude with the hands em-

ployed in its labours, and governed by many ridiculous practices converted by superstition into irrefragable laws, agriculture was wholly destitute of that estimation which is to requisite to animate every species of human industry.

"On this subject mention has been made of the kitchen-gardens established by order of Francis I. at Anet, near the forest of Yvry, under the inspection of a skilful gardener named Martin; but it appears that it was for Henry IV. at St. Germain-en-Laye, that arcades open to the south were first erected for accelerating the growth of peas.

"La Quintinie, who formed the superb kitchen-garden at Versailles, scarcely made any further advances; it is well known that fruits and flowers were at that time brought by post from Provence to Lewis XIV. for the gratification of his court.

"Fagon, at the Jardin-des-plantes, at Paris, caused some glazed sashes to be constructed for foreign plants, which, for want of sufficient light, could not flourish in the green-houses built for orange-trees, such as the superb *orangerie* at Versailles. To those sashes were added stoves and furnaces. But these methods were scarcely applied to forcing fruit till the reign of Louis XV.

"We are assured that an Englishman named Gordon was the first who made experiments of this kind, in consequence of observing that a vine-branch, which accidentally entered between two sashes of a window, put out leaves long before the rest of the stem, and that the forced grapes it produced ripened better.

"Hence arose all the hot-house sashes, the frame-lights, head-glasses, or covers, formed of small panes of glass, joined together in leaden frames, and those formed of large plate-glass. At length Richard Senior built, both for himself at St. Germain, and afterwards for the King at Trianon, hot-houses, in which were seen, for the first time in France, peaches, cherries, plums, strawberries, apricots, and vines, bearing fruit in the depth of winter, and lilacs, roses, honeysuckles, feringas, hyacinths, narcissuses, and other flowers, in full bloom.

"In the *Ecole du Potager*, written by Combes, about 1750, are the details relative to the management of the glass covers and sashes; but a great improvement still remained, which has been accomplished in the invention of the forcing-frames (*Pavillons de primeurs*), to which M. Bérard has been led by various and successive attempts now submitted by him to the public. As it has fallen to our lot to give an account of these attempts, and of the management of them, we ought in the first place to state the dimensions of the frame-lights composed of only two parts.

"The lower part, *a* (see Plate 30, figs. 1, 2, 3), is formed by the union of two square sashes, the lower about 13 decimetres (4 feet French; see MEASURE, *Supp.*), the upper only 9.

"The latter is raised above the former about 5 decimetres (13 inches French); and the two are joined by small iron rods fit for the reception of the panes of glass.

"The upper part *b*, consists of a wooden sash, bearing also four iron rods at the corners, and four in the middle, joined together at a single point *c*, where a heavy ring is affixed; the inclination of this upper part being less rapid, as in the broken roofs (*toits brochés*) of the common green-houses: it is only 3 decimetres by 8 for the half breadth.

"During the time when the vegetation, having grown up, requires more height in the building, a height of wood may be placed between the two portions to as to raise the upper part one decimetre, at least; another placed below would raise the whole, when needful, more than two.

"From this arrangement of the glass arises a mass of light extremely valuable to vegetation. The proximity of the glass is another advantage, which is the more important, as it is well

known that plants kept under glass become *étioil*, that is, grow weak by lengthening themselves to excess in order to reach and touch the glass, near which the influence of the sun is always greatest. And, lastly, the inclination of the glass, and its being placed in three different planes, increases more and more the effect of the solar heat.

"Shutters applied in succession, whether toward the north or toward the sun, protect the plants from the cold, or shield them from an excess of heat, and may be used throughout the whole during the winter nights.

"Thus, with mere glazed frame-lights, a great number of young and delicate plants may be reared, especially the finest melons and cantaloups; or more common productions may be accelerated, as strawberries, French-beans, and the early cabbages, as well as a variety of flowers: or smaller erections may be made for these various uses: but the extent of the ground thus preserved from the chilling moisture of cold rains is an advantage not to be neglected or forgotten; and frame-lights, of 13 decimetres square, being easily removed by one man, or cultivated to the midst of them, that size appears most convenient.

"All this, however, constitutes but half the merit of these hot-houses. It is evident they may be placed over a hot-bed, accompanied with chafing-dishes, and their shutters covered and surrounded with horse-dung when needful; though, as is well known, the heat of that substance, which is often difficult to be obtained, is still more difficult to be kept up.

"The heat of furnaces is liable to the same objections, on account of their extent, even in the smallest hot-houses. Another defect in these buildings is the distance of the plants from the glass. A third arises from the great mass of air heated to a loss; not to mention the no less important mass of the materials, naturally cold in themselves, of which the walls are built. Lastly, their being stationary is one of the greatest obstacles to their being employed in horticulture. They are an expence only to be incurred by land-owners, and by land-owners who live in affluence, or by an extremely small number of gardeners, industrious enough to derive from their hot-houses a quantity of fruit, which, if it does not enrich, indemnifies them at least for the expences attending this method, which has hitherto been the only one known.

"All these inconveniences seem to be avoided by the frame-lights, to which M. Bérard has adapted an apparatus for procuring heat from a kind of fuel equally convenient and economical, namely, two small furnaces, in one of which, *h*, is placed a strong earthen pan filled with the dregs of oil, or two, in case of extreme need; a second furnace, *g*, above, with another pan placed there at the time when the fire is lighted; an iron pipe, *f*, placed at the bottom of the frame, to warm the wood and earth by means of the smoke passing through it; the circulation of which smoke is furthered by the second furnace, where the end of the pipe passing through it receives a local heat, which rarefies the air throughout the whole pipe; a wooden box, *j*, to inclose these parts, which are constructed of thin materials; an iron pipe, *i*, terminating, if needful, in a T, to carry off the smoke when it has become useless. This is the whole apparatus, and about a kilogram of oil per night, value 12 and 15 cents the whole expence. 5 or 600 francs at most laid out in constructing two of these forcing-frames, with fire-apparatus, and four without, which are necessary for placing more at large the plants reared in the former, ought, according to M. Bérard's estimate, whose experience on this subject renders his opinion decisive, to produce as much effect as a hot-house that has cost 3 or 4000 francs, and which would require a consumption of several fathoms of wood.

"The economical gardener also finds an advantage in having it in his power to keep the parts not actually in use

under cover, by which they last longer, and their expence is consequently diminished.

"Lastly, by substituting a number of these forcing-frames for one hot-house, an advantage which must be considered as almost invaluable is obtained; that of varying the temperature, and accommodating it to the different plants they contain, as well as to their various periods of vegetation."

FORDINGBRIDGE, a town in Hampshire, with a market on Saturday; seated on the Avon, 20 miles W.S.W. of Winchester, and 87 W. by S. of London. Long 1. 49. W. Lat. 50. 56. N.

FOREZ, a late province of France, bounded on the W. by Auvergne, on the S. by Velay, and the Vivarais, on the E. by the Lyonnais, and on the N. by Burgundy and the Bourbonnois. It is watered by the Loire, and several other streams, and has several mines of coal and iron. It now forms, with the Lyonnais, the department of Rhone and Loire.

FORICULA (*Encycl.*). In that article, we omitted to refer the reader to (Plate 25, in vol. III.). To what has there been said we wish again to enter our protest against the truly vulgar opinion that this harmless insect (the *Earwig*) has the least disposition to enter the human ear by choice. Nothing, in fact, is so repugnant to its habits as moisture, and particularly of that clammy kind which the ear supplies, and which must be a great impediment to the freedom of its motions. In the first summer of the militia encampments in the former war with France, a whole regiment were assigned some ground on the downs near Winchester, which literally *swarmed* with these insects. During the whole season not a single instance occurred of an earwig's taking up its abode in the human ear. One soldier only, out of nine hundred, met with the accident of an earwig's falling into his ear from the top of the tent in which he lay asleep; but even this occasioned him no great inconvenience; the insect was at once killed by pouring a little oil into the ear, and extracted by syringing with warm water.

FORGES, a town of France, in the department of Lower Seine, remarkable for its mineral waters. It is 60 miles N.W. of Paris. Long 0. 40. E. Lat. 49. 38. N.

FORNELLO, a town of Naples, in the Molise, 17 miles W. of Molise.

FORNOVO, a town of Italy in the duchy of Parma; near which, in 1495, Charles VIII. of France obtained a victory over the princes of Italy. It is eight miles W.S.W. of Parma.

FORTALICE, in Scots law, signified anciently a small place of strength, originally built for the defence of the country; and which on that account was formerly reckoned *inter regalia*, and did not go along with the lands upon which it was situated without a special grant from the crown. Now, fortalices are carried by a general grant of the lands; and the word is become synonymous with manor-place, messuage, &c.

FORTIEVENTURA, one of the Canary Islands, 65 miles in length, and of a very irregular breadth, consisting of two peninsulas, joined by an isthmus 12 miles in breadth. It produces plenty of wheat, barley, beeves, and goats. Long. 14. 26. W. Lat. 28. 4. N.

FORTROSE, a borough in Roxburghshire, situate on the Frith of Murray, nearly opposite Fort George, and nine miles W. of Inverness.

FOSSANO, a strong town of Piedmont, with a bishop's see, situated on the Sture, 10 miles N.E. of Coni, and 27 S.E. of Pignerol. Long. 7. 56. E. Lat. 44. 45. N.

FOSSÉ, a town of Westphalia, in the bishopric of Liege,

situate between the Sambre and Meuse, seven miles W. of Namur. Long. 4. 40. E. Lat. 50. 26. N.

FOSSIL ALKALI (*Encycl.*). The nature and chemical properties of this substance have been fully set forth; but it may not be improper to describe some of the means by which it may be separated from sea-salt, of which it is the basis.

In August, 1781, a patent was granted to Mr. ALEX. FORDYCE, for his new processes, by which the alkali contained in sea-salt, rock-salt, salt-springs, salt-cake, Glauber's salt, and vitriolated tartar, may be separated from the marine or vitriolic acids.—He first converts salt-water, &c. into Glauber's salt, by the application of vitriolic acid, or of any substance containing the latter. This salt is then to be mixed with a double quantity of lime, chalk, or any other calcareous earth, or iron, or with any substance containing that metal. The whole is to be placed together in a vault, or other reservoir, secured from the rain, till it is completely decomposed, when the alkali is to be extracted by dissolving it in water and evaporating it to dryness. Or, the patentee employs 60lbs. of Glauber's salt, or vitriolated tartar; 10lbs. of charcoal, or any other substance capable of bearing heat, and containing the inflammable principle; and 10lbs. of iron; these ingredients are pounded together, and thrown into forty gallons of water; where they are suffered to digest for twenty-four hours. The clear solution is then to be separated; and, by evaporating, filtering, and crystallizing, it is rendered fit for use.

Another patent was granted in March 1789, to Mr. ANTHONY BOURBOULON DE BOURNEUF, of Liverpool, for his invention of an apparatus on a new construction, and certain new processes for the making of fossil alkali, which is said to be equal to that extracted from the best barilla. As, however, this specification is so complex, that it could not be understood without the aid of an engraving; and, as the patent is not expired, we refer the reader to the 4th volume of the *Repository of Arts and Manufactures*.

The last process which merits our attention, is that of the Earl of DUNDONALD, for obtaining mineral, or fossil, and vegetable alkali, from neutral salts composed of those alkalies and an acid; or from the solutions of those salts, whence several articles are disengaged or formed, that may be collected and applied to various useful purposes. For these different inventions, his lordship obtained a patent in 1795*. 1. The most important of the new processes, is that of making Glauber's salt, or sulphat of soda, which is one of those neutral salts, consisting of an alkali and an acid, from which an alkaline salt is to be procured. Thus, several other articles, such as spirit of salt, sal ammoniac, and an iron earth mixed with clay, as a pigment, are formed, or disengaged, and may be collected: 2. Glauber's salt is decomposed, forming mineral alkali, or soda, either in a mild or caustic state: 3. Vitriolated tartar is prepared by decomposing the muriat of pot-ash; and 4. This preparation is converted into either a vegetable alkaline leepar, or mild or caustic vegetable alkali. The salts and other substances resulting from these chemical operations, may be applied to various purposes, particularly for decomposing soda, from Glauber's salt.

As the principal article for which Lord DUNDONALD has established manufactories, appears to be the SODA now generally sold in the shops, we shall, in the alphabetical series in this Supplement, describe its manifold uses, and content ourselves at present with giving a summary of the inventions claimed by the noble patentee: namely, that sea-salt is decom-

* We have authority to say, that some part of Lord Dundonald's claim has no just foundation, the discovery of the manufacture of Glauber's salt from the refuse of the alum works having been many years ago made, and extensively practised by Mr. Houlston, an ingenious medical practitioner and chemist, now living in Liverpool.

posed by alum, by vitriol of iron, and Epsom-salt, with the aid of heat, when a due proportion of clay, or a clayey iron earth, is mixed with the salts submitted to the operation;—that sea-salt is also decomposed by Epsom-salt with the aid of heat, and without the intervention of clay;—lastly, that it may likewise be reduced by sulphat of lime, or gypsum, with the aid of heat, when a due proportion of clay, containing much iron, is mixed with the sea-salt and gypsum.

FOSFIL-COAL (*Encycl.*). In December 1792, a patent was granted to Mr. JOHN BARBER, of Attleborough, Warwickshire, for a method of smelting and purifying fossil-coal, ironstone, iron-ore, &c. By steam, air, and fire, and for impregnating the same with inflammable air, by which he produces a tough metal.

The patentee directs any portion of iron-stone, or ore, together with a quantity of fossil-coal, to be put into a furnace, into which fire is to be admitted, and steam conveyed from a boiler, by means of pipes, through an aperture made in the hearth. These pipes are not to project into the furnace, but only to extend so far as to permit the steam to convey along with it a quantity of atmospheric air; and thus a calc sufficiently pure will be produced. The process of purification may be facilitated, by placing a vessel of water at the bottom of the furnace, or building, for the reception of the hot calc while it falls, or is disengaged. And if sometimes a proper proportion of sal-ammoniac, or other menstruum, be thrown in among the coals, &c. while purifying, that operation will be, in a considerable degree, facilitated.

When the calces are thus prepared, a portion of them, and also a portion of fossil-coal, or purifying coals, are to be put into a smelting furnace, beneath which a fire is to be kindled. Apertures are also to be made for the introduction of inflammable air, from one or more retorts, by means of pipes, either singly or conjointly with *air-blas*. Lime-stone, charcoal, and other substances abounding with inflammable air, may be added in due proportions, and will have an effect similar to that produced by the inflammable air alone, for which it may be occasionally substituted. The patentee observes, that the proportionate quantities of the various materials employed, can only be ascertained by experience; and the result of this process will be the production of a tough metal, capable of being applied to several useful purposes.

FOSFIL-WOOD (*Encycl.*). At one of their meetings, Citizen Villars announced to the National Institute the discovery of fossil woods buried on the summits of the highest mountains of the Alps, almost 2500 feet above the highest of the nearest forests now in existence. He has noticed larch, birch, alder, and aspen, the trunks of which, as well as the roots, are in a state of perfect preservation. From this appearance, Villars concludes, they must have vegetated in the very spot where he found them, but is at a loss to conceive how the cold could become so violent as to render it impossible for the same trees to live except at a great distance. He attempts to account for it by the melting away of the tops of the mountains, the attenuation of their chalk by rain, and the imprudent destruction of their forests by the hand of man. Poirer mentioned that he had found shells of fresh-water fish buried under beds of turf, over which again were other beds, containing sea-shells. It should thus appear, that the earth which exhibits these appearances had been first watered by streams, then inundated by the sea, and now was placed in the centre of a continent. Beauvois produced from North America proofs no less astonishing of changes in the state of the earth, in which at different epochs had been found remains of monstrous quadrupeds, at this day unknown; and he produced specimens of skeletons which had been dug up, differing from those observed at preceding times. Every day, every climate

furnishes documents of the revolutions which our globe has undergone, and which are indelibly impressed on its surface, and in its entrails. Thus does man, unable to develop the mysteries of his own existence, attempt to explore the arcana of the created globe, which seem to deride the efforts of knowledge, and mock the exertions of science! philosophy furnishes no means for penetrating into the causes of those events which are buried from the search in an inscrutable antiquity.

FOSSOMBRONE, a town of Italy, in the duchy of Urbino, with a bishop's see; seated near the river Metro, 16 miles S.W. of Pesaro, and 12 S.E. of Urbino. Long. 12. 48. E. Lat. 43. 40. N.

FOUE, an ancient town of Lower Egypt, seated on the Nile, 25 miles S. of Rosetta, and 40. E. of Alexandria. Long. 31. 15. E. Lat. 31. 12. N.

FOUGERES, a town of France, in the department of Maine and Loire, with an ancient castle. It is seated on the Cosson; 25 miles N.E. of Rennes, and 150 W. of Paris. Long. 1. 13. W. Lat. 48. 22. N.

FOULI, or **PHOLEY**, a country of Africa, situate on the sides of the river Senegal, and extending about 500 miles from E. to W: the boundaries from N. to S. are unknown. It is populous and fertile. The inhabitants are, in general, of a tawny complexion, though many of them are entirely black. They lead a wandering life, and roam about the country with large droves of cows, sheep, goats, and horses. The king of this country is called the Siratick; and though he seldom appears with the badges of majesty, he has great authority, and is as much respected as any one on the coast. Though none but princes of the blood can be called to the throne, yet the crown descends not from father to son, but from brother to brother, or nephew to nephew. The people of Foui are greatly praised by travellers for their hospitality: nor is their humanity, in other respects, less commendable; for, if one of their countrymen have the misfortune to fall into slavery, the rest join stock to redeem him. Elephants are so numerous in this country, that they are frequently seen in droves of 200 together. The natives are very dexterous at hunting them, and other wild beasts; as elephants' teeth and the skins of lions, leopards, and tigers, are their principal articles of trade; and their flesh they dry for use and winter-store.

FOULNESS, an island separated by a narrow channel from the S.E. part of the county of Essex, six miles E. of Rochford.

FOULSHAM, a town in Norfolk, with a market on Tuesday, 16 miles N.W. of Norwich, and 111 N.E. of London. Long. 1. 7. E. Lat. 52. 51. N.

FOURNEAUX ISLAND, a small island in the S. Pacific Ocean. Long. 143. 2. W. Lat. 17. 11. S.

FOXFORD, a town of Ireland, in the county of Mayo, situate on the river May, eight miles N. of Castlebar.

FOX-GLOVE. See **DIGITALIS** in this Supplement, where an account is given of its medical properties.

FOYLE, **LOUGH**, a lake or bay of Ireland, in Londonderry. It is of an oval form, 14 miles long and eight broad, and communicates with the ocean by a short and narrow strait.

FOZ, a town of Portugal, in Alentejo, situate at the conflux of the Zaras and Tagus, 24 miles N.E. of Lisbon. Long. 8. 56. W. Lat. 38. 58. N.

Foz, a town of France, in the department of Var, four miles N.E. of Barjols.

FRAGNINO, a town of Naples, in Principato Ulteriore, eight miles N. of Benevento.

FRAGOAS, a town of Portugal, in Estremadura, seven miles N.W. of Santoren.

FRAMPTON, a town in Dorsetshire, with a market on Thursday, seated on the Frome, 12 miles N.W. of Weymouth, and 126. W. by S. of London. Long. 2. 50. W. Lat. 50. 45. N.

FRANCE (*Encycl.*). The following account of the Calendar of the French Republic, since the abolition of Royalty, we extract from the British Magazine.

The republican era began,

Year	1	-	-	22	September 1792
	2	-	-	22	1793
	3	-	-	22	1794
	4	-	-	23	1795
	5	-	-	23	1796
	6	-	-	22	1797
	7	-	-	22	1798
	8	-	-	23	1799
	9	-	-	23	1800
	10	-	-	23	1801

Each year consists of 12 months.

1	Vendemiaire, year 8, was	-	-	23	September.
1	Brumaire,	-	-	23	October.
1	Frimaire,	-	-	22	November.
1	Nivose,	-	-	22	December.
1	Pluviose,	-	-	21	January.
1	Ventose,	-	-	20	February.
1	Germinal will be	-	-	22	March.
1	Floral,	-	-	21	April.
1	Prairial,	-	-	21	May.
1	Messidor,	-	-	20	June.
1	Thermidor,	-	-	20	July.
1	Fructidor,	-	-	19	August.
5	Complementary days, 18	-	-	22	September.

Each month has 3 decades of 10 days.

1.	Primidi.	6.	Sextidi.
2.	Duodi.	7.	Septidi.
3.	Tridi.	8.	Octidi.
4.	Quartidi.	9.	Nonidi.
5.	Quintidi	10.	Decadi.

Once in four years there are six instead of five complementary days. These days are named like the five or six first of the decade.

The republican year begins at the midnight preceding the autumnal equinox. Alm. nat. an. 9. The metre has been ultimately determined to be equal to 3 feet, 11.296 lines French, the gramme to be 18.827 grains, Journ. de Physique, an. 7. Prair. et Fruct. The metre is the ten millionth part of the distance from the pole to the equator: the gramme the weight of a cubic centimetre of water. The toise was 76.734 inches English, and 576 French grains were equal to 472.5 English. Phil. Trans. v. 58, p. 326, and v. 42, p. 187.

FRANCHEMONT, a town of Germany, in the bishopric of Liege, 12 miles S.E. of Liege.

FRANCIS of Assisi (St.), founder of the Franciscan friars, was born at Assisi in Italy in 1181. One of the most extraordinary things told of St. Francis of Assisi, that Jesus Christ imprinted on him the marks of his five wounds; and there is a festival in memory of those holy prints, and an office for it. His preaching to the fishes to make them Christians, and his conversion of millions of them, is famous; as is his mercy to worms and lice. The order he founded, and which bears his name, was approved by Innocent III. in 1215, and confirmed by Honorius III. in 1223. It has since branched into several others, as Minims, Ricolets, Capuchins, &c. called in Roman Catholic countries, *Frates Minores*.

FRANCOIS, CAPE, a town in the N. part of the island of St. Domingo. It suffered much by dreadful commotions
VOL. X.

that ensued after the French revolution. Long. 72. 18. W. Lat. 19. 46. N.

FRANEKER, or **FRANKER**, a town of the United Provinces, in Friesland, with a castle and university. The public buildings and palaces are magnificent. It is seven miles W. of Lewarden. Long. 5. 33. E. Lat. 53. 11. N.

FRANKENAU, a town of Germany, in the principality of Hesse, 24 miles S.W. of Cassel.

FRANKENBERG, a town of Upper Saxony, seven miles N.N.E. of Chemnitz, and nine W. of Freyberg.

FRANKENHAUSEN, a town of Upper Saxony, with some extensive salt-works. It is situate on a branch of the Wipper, 26 miles N. of Erfurt. Long. 11. 5. E. Lat. 50. 42. N.

FRANKENSTEIN, a town of Germany, in the palatinate of the Rhine, 12 miles N.W. of Landau. Long. 7. 55. E. Lat. 49. 18. N.

FRANKENSTEIN, a town of Silesia, on the Bautze, 12 miles S.S.W. of Glatz.

FRANKLAND'S ISLANDS, a cluster of islands in the South Pacific Ocean, on the N.E. coast of New Holland. Long. 146. 0. E. Lat. 17. 10. S.

FRANKLIN, a county of Pennsylvania, 30 miles long and 24 broad. In 1790, it contained 15,655 inhabitants. Chamberberg is the capital.

FRANQUEMONT, a town of Switzerland, in the bishopric of Basle, often besieged and taken in the Swiss wars. It is seated on the Doubs, 16 miles N. of Neuchatel, and 23 W. of Soleure.

FAUENFELD, a town of Switzerland, capital of the Thurgau. It is seated on an eminence, and is the place where, since 1712, the deputies of the Swiss cantons hold their general diet. Long. 8. 56. W. Lat. 51. 48. N.

FREDEBERG, a town of Westphalia, 50 miles W. of Cassel. Long. 8. 16. E. Lat. 51. 10. N.

FREDERICSHAM, a town of Russia, in Carelia. It is neatly built, the streets going off like radii from a centre; and is seated near the gulf of Finland, 68 miles W.S.W. of Wiburgh.

FREDERICSTOWN, a flourishing town of the United States, in Maryland, seated on the Potomac, 60 miles W. by N. of Annapolis. Long. 77. 30. W. Lat. 39. 20. N.

FREE-CHURCH, a name given to certain places of Protestant worship, established of late years with a view to encourage among the poor a regular observation of the sabbath. In London and Bath these establishments have been found to answer an excellent purpose. The following extract from an account of the free-church at Bath, by Mr. Bernard, appears in the Reports of the Society for bettering the condition of the poor, &c.

The free-church, in the parish of Walcot, at Bath, was opened in November, 1798, for the general and indiscriminate accommodation of the poor. The idea was originally suggested by the Rev. Mr. Daubeny, in a sermon delivered at St. Margaret's chapel, at Bath, in April 1792; and afterwards, with the concurrence and approbation of the Rev. Mr. Sibley, the rector of the parish, published with an address to the inhabitants.

In this discourse, Mr. Daubeny, after enlarging upon the great characteristic of the Christian religion, that, "The poor have the gospel preached to them," and upon the expected benefits of the Sunday schools then established at Bath, proceeded to ask "where are the children of that place when discharged from the Sunday schools, at a time of life the most dangerous—where are they to gain that instruction, which is calculated to bring to perfection the education which they

have received? If, in conformity to the ideas with which they have been brought up, they come to places of worship belonging to the establishment, they find, alas! the doors, for the most part, shut against them."—He then goes on to observe, that this is, in some degree, to exclude them from the established church, instead of inviting them, and providing places of worship for them; without which (he adds) "we cannot be surprised that they should no longer continue members of a church which, in a manner, *excommunicates* them. In which case their infidelity, and consequent immorality, will not so much lay at their own doors, as at the doors of those who ought, in charity, to have taken their case into consideration, and to have provided means for their instruction."

This discourse had its due effect on the audience, and several hundred pounds were immediately subscribed among them, before they quitted the church. With the example of some principal subscribers; both among the clergy and laity, the subscriptions, in a short time, amounted to £2700. Any objections which might have occurred to doubting minds, were obviated by the publication of the plan; which was, that though the church was to be free from all parochial duty and control, yet it was to be consecrated by the bishop of the diocese, and the officiating ministers licensed by the bishop, in confirmation of their appointment by the rector of the parish: that the whole area of the building should be appropriated to the free accommodation of the common people; and the seats in the galleries should be let out to tradesmen, and persons in a superior rank of life, at such prices as might furnish a sum sufficient for the service and repairs: that there should be a full service both morning and afternoon every Sunday, and a sacrament once a month; and lastly, that the building itself should be vested in trustees, with powers and provisions adequate to the purpose of securing it to the public for ever, in conformity to the design with which it was originally constructed.

The conductors of this exemplary undertaking having purchased for £300, a leasehold piece of ground, in an airy situation, in the centre of the parish, as a site for the new church, Lord Rivers, in whom the fee-simple of the ground was vested, made them a handsome offer of his remaining interest in it; so that it was made *free ground* in perpetuity. This offer having been carried into effect, a plain but handsome gothic edifice was then erected; Mr. Daubeny taking upon himself the risk of any expense beyond the amount of the subscriptions. It is calculated to accommodate 1000 persons in the area, which is the free part of the church; and between three and four hundred persons in the galleries, the produce of which is appropriated to defray the annual outgoings. The church was consecrated on the 7th of November, and opened for divine service on Sunday, November 18, 1798. The cost of the church rather exceeded £3500; not including those ornamental articles, which have been contributed as the donations of several persons, in addition to their original subscriptions; and an organ, which has been deemed necessary to lead to large a congregation to join in the singing part of the service, and to operate as some additional inducement to their attendance.

Mr. Bernard attended the evening service there, on the 24th March, 1799. The gallery, indeed, was not above half filled, the seats being reserved for the renters of them; but the area below contained above a thousand persons, decently and cleanly dressed, and receiving the benefit of divine worship, with a degree of propriety and attention, that made the service extremely awful and impressive. It was a sight that must have given the greatest satisfaction to every zealous Christian, who had an opportunity of participating in this act of devotion;

whilst the gratitude that is expressed by the lower orders of people for the accommodation so liberally provided for them; and the eagerness with which they attend the service of the church, furnish the most favourable omens of the good effects that may be derived from an establishment of this truly pious and charitable nature. The propriety and expediency of the provision made, in this instance, for the religious duties and instruction of the poor at Bath, are so obvious and unquestionable, that it is difficult to state any reasons in their favour, which will not have already occurred to the reader's mind, on the perusal of the preceding account. It is very apparent that the free church at Bath must greatly contribute, in that place, to the improvement of moral and religious habits among the lower classes of society, to the prevalence of the established church, and to the permanence and stability of internal peace and civil order. It must be equally apparent to every one, who has turned his attention to the situation of the poor in London, and to their means and opportunities of exercising their religious duties, that several such chapels, as the free church at Bath, are now wanted in our metropolis; and that, without such chapels, the poor, though living in a Christian country, do not possess the common benefits of that religion, which its divine Author addressed principally to them. If even with those who have had the blessing of a religious education, and have had the books of revelation opened and explained to them,—if even in their instance "religion, the rewards of which are distant, and which is animated only by faith and hope, will glide by degrees out of the mind, unless it be invigorated and re-impressed by external ordinances, by stated calls to worship, and by the salutary influence of example," what must we expect of the ignorant and uneducated? of those who are pressed down by necessity, and have no support derived from the truths of revelation, or from the principles of morality?

It is mere mockery to give the name of *accommodation*, to the space that is left for the poor, in the aisles of our churches, in London and Westminster. They are neither adapted to the performance of the duties of religious worship, nor would they contain a *fiftieth* part of those, *who ought to be accommodated there*. While the rich are conveniently seated for their money, the poor should not be neglected. They should, as far as kindness and attention will go, be *compelled to come in*. They should have the advantage of their residence in a Christian and Protestant country; and inducement should be held out to them, such at least as decent and comfortable seats would afford, to attend regularly at the established church, and to unite with the rest of their fellow-subjects, in the constant observance of the sabbath, and in religious worship.

In the following year, namely, on Sunday, the 25th of May, 1800, a free chapel was opened in West-street, near the Seven Dials, in London, for the benefit of the poor. Those who have witnessed the pathos and energy with which the truly pious and learned Dr. Porteus, bishop of London, delivers and enforces the divine truths and ordinances of the gospel, may conceive how powerful and impressive his discourse must have been, on this occasion; addressed as it was to the feelings and understandings of his audience, and received by them with silent and unfeigned satisfaction.

The necessary arrangements were immediately made for the care of the chapel; which was placed under the direction of the bishop of the diocese, the rector of the parish, and eight of the principal subscribers. The duty has been since regularly attended, and the psalms and hymns printed, and placed for the poor in their pews; and there has been gradually forming a pious and decent, though not, as yet, a numerous congregation.

It had been conceived that it would be better, and more conducive to the permanency of the institution, that the poor should *gradually* find their way into the chapel; rather than by any special means to prefs their premature attendance. No hope was entertained that their habits would be suddenly and entirely changed; and that those who from infancy had passed the Lord's day in sloth and brutal indulgence, should be *at once* amended; and be prepared regularly to attend with cleanliness and decency, in a place of divine worship. A complete and permanent reform was not to be immediately expected; and a temporary conformity, a mere yielding for the time to pressing instances, compelling them to come in, did not promise any final improvement.

An organ has been lately provided for the chapel, and an organist engaged; and a respectable clergyman officiates as the minister of the chapel. Whoever takes a view of the parochial districts, at the western end of London, will find that, in the four parishes of Marylebone, St. James's, St. Giles's, and St. George's, Hanover-square, with a population of some hundred thousand inhabitants, there are only *four churches* for the reception of those who are desirous of attending divine worship, according to the rites of the church of England.

Three of these are of a moderate size; but the other, that of Marylebone *, only fit for the chapel of some petty, insulated hamlet. In these four parishes, the *utmost* exertions of the parochial clergy, combined with the greatest talents, must be utterly inadequate to the religious duties of their respective districts †. Besides which, in these, and in almost every other church in the metropolis, the pews are let; and the only places left for those parishioners who wish to continue members of the established church, and yet cannot afford to pay a very heavy rent for their seats, is the *standing room* in the aisles, and sometimes an occasional neglected bench; an accommodation, improper, indecent, and unfit for the sacred and solemn service then attended; and such as, even if decent in itself, would not be adequate to the admission of *one-hundredth part* of those who ought to have seats in their own parish church.

It is of very little or no consequence, that, in these four parishes, there are many private chapels. Those chapels are let at *rack-rent*, to some speculating undertaker: the pews, and every part of them, being laid out and disposed (as other private property generally is) *so as to produce the greatest possible income with the least outgoings*; and the free admission of the poor being directly opposite to the principle on which they are built and opened, and perfectly incompatible with the *great object*, of making a very large revenue, by the admission of very genteel company.

The consequence of this is, that many of the better and more serious of the labouring poor are driven and compelled, to take refuge in the different places of worship, which the more accommodating spirit of other Christian sects provides for their religious duties. But this is not all: the greater number of these neglected Christians *prefer* their *orthodoxy*, by *never attending any church at all*; and, in a country, justly boasting of the purity of its religious doctrines,—extremely fortunate in the possession of a pious and learned clergy,—and

consecrating very ample funds to the support of a most respectable church establishment,—two thirds of the lower order of people in the metropolis, live as utterly ignorant of the doctrines and duties of Christianity, and are as errant and unconverted pagans, as if they had exited in the wildest part of Africa.

To those who view, with a fixed and attentive eye, the awful series of events which is now desolating, and we may hope at the same time reforming, the Christian world, much important observation will occur on the present subject. It is written in the recent History of Europe, it is inscribed in the summary of the ten preceding years, that there is no protection against the calamities which are now laying waste our quarter of the globe, except that purity of faith and integrity of life which are to be derived from the vivifying influence of religion; extending, like the solar ray, to *every clays* of our fellow subjects, and operating in the moral amendment of the great mass of the people.

It has been the object of some individuals, and certainly a very desirable object, that Sunday should be observed among us with more decency and devotion than are at present apparent in the metropolis: and it has been frequently observed, that, in the gradual progress from petty offences to those atrocious crimes which strike at the very root of society, the habitual neglect of the sabbath, and of its sacred ordinances, is always a prominent and peculiar feature. It is by the gradual effects of that neglect, that the reverence of the Divine Being, implanted as it is in our frame, and nourished and confirmed by every object of creation, is at length eradicated from the human breast; and the hardened sinner is ultimately left a prey to his own evil and corrupt imaginations.

But, surely, it must appear to be an obvious truth, that, if we would promote the religious observance of the Lord's day among the poor, we must not merely set them the example, but must ourselves make the provision for their religious duties. Without this, there is no use in the increase of vain statutes, which can never be executed to any good purpose; statutes, which can, in no event, produce more than the *semblance* and *shadow* of religion in the country. It may, however, be confidently asserted, that with the benefit of such a provision, effectually and properly made, and eventually accepted and enjoyed, we should have little or no call for any new law or ordinance on the subject; but we should find, among the great mass of the people, the same attention to the religious duties of the Lord's day, as is now shewn by the individuals of those Christian sects among us, who make a decent and proper provision for the religious duties of their necessitous brethren.

The periodical return of the seventh day, for the instruction of the minds of the poor in divine knowledge, and for the rest and relaxation of their bodies from the cares and labours of life, is, in the Christian world, a most important advantage; whether we regard the situation of the labouring class in this fleeting period of existence, or whether we turn our views to the awful and interesting concerns of futurity. But it is vain to expect, that the poor should regard that day

* The population of Marylebone is now returned, and the size of that parish church may easily be known. It will therefore not be difficult to ascertain whether the population of that parish requires 150 such parish-churches as its present; or whether 120 such churches would be sufficient for the inhabitants.—June 27, 1801.

† Those who attend the poor of the metropolis in their own habitations, have frequent and painful occasion to lament their want of that instruction and consolation in their dying moments, which Christian charity would desire them to receive. In other sects, and in country parishes, where all the members of a congregation are personally known to the ministers, these duties may be completely fulfilled; but in the populous and extended parishes of the metropolis, no zeal, however indefatigable, can enable the present number of clergymen to do *all that ought* to be done.—June 30, 1801.

as any thing but a privileged time for idleness and intemperance, except from the call to toil and labour, unless we supply them with other occupation, and furnish their minds with that religious instruction *, and with those precepts and motives, which may have an operative effect upon their lives and conduct: and, when so long and so general a neglect has taken place, it is vain and idle to expect that, without much time, much attention, and much anxiety on our part, the poor should immediately and spontaneously flow into the chapels that may be opened for them. The evil (it must be allowed) is too deep, and the habit too inveterate, to admit any expectation of that kind. But the benefit of *such a reform, in London*, is so great, and so important in its consequences; it is so essential to the political existence of this country, and to the security and happiness of its inhabitants; that I know no object, the advantages of which I can name in preference to, or even in competition with it.

With these sentiments, and with this conviction on his mind, Mr. Bernard submits to those, from whom only such a measure can properly originate, the expediency of providing some remedy for this national evil.

His proposal is, that a society be formed for *promoting the foundation and establishment of free chapels for the poor, and the increase and improvement of their religious habits, within the realm of England*—that every subscriber of fifty guineas in one sum, or of five guineas a-year, shall be a governor of the society; and that in case of a donation of 100 guineas or more, the donor shall, for every 50 guineas beyond what would constitute his own subscription, have the power of naming one life governor: the specific appropriation of the funds being for the establishment and support of free chapels for the poor, in the metropolis, and in any of the populous towns of England; subject, as all other chapels and churches of the established church must be, to episcopal control and government.

Whenever such a society shall be formed, and the directing power placed in unexceptionable hands, we may venture to hope that some addition to its funds may be afforded by government. It may also be expected, that, with a proper and economical application of those funds, every thousand pounds entrusted to the direction of it, may afford the means of forming and establishing a new free chapel for the poor, either in London, or in Manchester, Bristol, Norwich, or in some other of our most populous towns.—What the effects may eventually and ultimately be, and what strength and stability it may give to the civil and ecclesiastical establishment of the country, and what renovation of vigour and force to the moral and religious habits of the poor, we leave to the reflection and appreciation of the reader. Our earnest wishes are in unison with those of the benevolent writer of these remarks, and we think ourselves fortunate in contributing to so laudable a work, by giving circulation to the excellent arguments used to enforce its necessity.

FREHEL, a cape of France, in the department of the North-Coast, 13 miles W. of St. Malo. Long. 2. 20. W. Lat. 48. 41. N.

FREJUS, a town of France, in the department of Var.

By the Romans, it was called *Forum Julii*; and had then a port on the Mediterranean, which is now above a mile from it. It is the birth-place of that great Roman general and philosopher Agricola; and near it some fine remains of antiquity are still visible. It is seated near the river Argens, in a morass, 40 miles N.E. of Toulon. Long. 6. 50. E. Lat. 43. 26. N.

FRENAY-LE-VICOMTE, a town of France, in the department of Sarthe, nine miles S.S.W. of Alençon. Long. 0. 5. W. Long. 48. 15. N.

FREUDENSTADT, a strong town of Suabia, in the Black Forest, built to defend the passage into this forest. It is 12 miles S.E. of Straßburg. Long. 8. 21. E. Lat. 48. 28. N.

FREUDENTHAL, a town of Silesia, celebrated for its breed of horses, and manufacture of fine linen. It was taken by the Prussians in 1741 and 1744, but afterwards restored. It is 11 miles S.W. of Jagendorf, and 17 W. of Troppau. Long. 17. 21. E. Lat. 50. 3. N.

FREYBERG, or **FRIEDBERG**, a town of Upper Saxony, containing above 60,000 inhabitants. In the environs are mines of copper, tin, lead, and silver, which employ a great number of workmen, and produce above 10,000rix-dollars a-year. Here is the usual burying-place of the princes of the electoral house of Saxony. It is situate on a branch of the Muldan, 15 miles S.W. of Dresden. Long. 11. 10. W. Lat. 51. 0. N.

FREYSINGEN, a town of Germany, capital of a bishopric of the same name, in the circle of Bavaria. It was taken by the French in 1796. It is seated on a mountain, near the Her, 20 miles N. by E. of Munich. Long. 11. 50. E. Lat. 48. 26. N.

FREYSTADT, a town of Hungary, in the county of Neitra, with a strong castle, seated on the Waag, opposite Leopoldstadt. Long. 18. 10. E. Lat. 48. 32. N.

FREYSTADT, a town of Silesia, in the duchy of Teschen; 20 miles E. of Troppau. Long. 18. 15. E. Lat. 50. 0. N.

FRIAS, a considerable town of Spain, in Old Castile, seated on a mountain, near the river Ebro, 35 miles N. of Burgos. Long. 3. 46. W. Lat. 42. 52. N.

FRIDAW, a town of Germany, in the duchy of Stiria, 104 miles S. of Vienna. Long. 16. 12. E. Lat. 48. 20. N.

FRIDING, a town of Suabia, on the Danube, 30 miles N.E. of Constance. Long. 9. 31. E. Lat. 48. 11. N.

FRIIDLAND, a town of Bohemia, on the confines of Silesia, 55 miles E. of Dresden. Long. 15. 15. E. Lat. 52. 4. N.

FRIELENGEN, a town of Suabia, three miles east of the Rhine, and four N. of Balle. Long. 7. 36. E. Lat. 47. 40. N.

FRIENDLY SOCIETIES, certain associations of mechanics and labouring persons, for the purpose of subsisting themselves and their families, when rendered incapable of labour by sickness, &c. They have been otherwise called **BENEFIT CLUBS**, and the good effects of the few private ones that have existed, have induced government to countenance them, and benevolent individuals to increase their number in the united kingdom. The following extract from an account of a friendly society at Castle-Eden, in the county of Durham, by Rowland Burdon, esq. will afford an excellent example.

* "I submit (says Mr. Bernard) to the reader's consideration two leading questions, respecting what, in my view of this interesting subject, is due to the poor.—The first, whether the poor have not a claim on the rich and independent, for a certain portion of that time which is not occupied by a proper attention to their domestic or public occupations, or by a reasonable relaxation of leisure and amusement? (*care and wretched anxiety* being the consequence of *excess of application* in respect of the first;—and of the latter, *weariness and listlessness of spirit*). The second question is, whether the ministers of the gospel can quite satisfy themselves, that the general duties of the clerical order are completely fulfilled, until the gospel has been really and effectually preached (as far as may be done) to every class of men in the kingdom? And in the mean time, whether any thing which they can do in the performance of works of supererogation, or even in attempts to convert distant nations, can be admitted as a commutation of their own peculiar and indispensable service?"

The trustees of the society are, the lord of the manor, the clergy and justices of that and the two adjacent parishes, within which its members for the most part reside. All donors or subscribers of one guinea and upwards, annually, are honorary members. Twelve principal inhabitants, with the churchwardens of the three parishes, and all honorary members, are directors for the time being. For the immediate management of the business of the society, an annual committee, with a steward, clerk, and treasurer, are elected, and two visitors are appointed from each parish.

The number of members has never reached two hundred; consisting for the most part of farmers, artificers, labourers, and their families. The following are the accounts from August 10th, 1793, to December 31st, 1796.

Vol. X.

Sixpence is paid for each share on the decease of every member, for whose funeral the society has any disbursement to make; and each member above twenty-one years of age (excepting women) pays, at each yearly meeting, one shilling for dinner and liquor: but no member is obliged to be at any expense at monthly or other meetings. A deposit of two shillings and sixpence is made on proposing any person to become a member, which, if the person be not admitted, is returned. Any member, under forty-five years of age, may increase his or her original share, on contributing according to his or her age, at the time of making such increase.

The following are the benefits to men in sickness, lameness, or infirmity; but women are not entitled to benefit in sickness.

For one share, and so in proportion for half a share:

Six shillings a-week, when confined in bed, or unable to go out of the house, or to perform any kind of work; and

Three shillings a-week, when able to walk out, or to labour to a final degree: but both these allowances cease when the member is able to follow his usual occupation, or even to earn three shillings a-week regularly.

A surgeon and apothecary are appointed to attend the sick members.

In old age.—For each share, and so in proportion for a half share, each member is entitled to the following annuity:

from 50 to 60 years of age, a yearly annuity (by quarterly payments) of	to men		to women	
	£.	s. d.	£.	s. d.
from 50 to 60 years of age	—	—	4	—
from 60 to 70 years of age	6	—	6	—
from 70 to 80	—	—	8	—
from 80 to 90	—	—	10	—
from 90 until death	12	—	12	—

Such annuities to commence from the first of January next, after the member's attaining the age of fifty, sixty, seventy, eighty, and ninety years respectively; but no annuity is payable to any member, until he shall have contributed for fifteen years, nor for any share on which he may have received relief in sickness, &c. but a man may take relief in sickness for one share, and receive annuities for other shares, which occasion many of the members to subscribe for more than one share.

At death.—Five pounds for each share, and fifty shillings for each half share, is paid to the representative of each member, who has contributed to the fund for twelve months, whether man or woman: and if the member die before contributing twelve months, the full amount of what he or she may have paid, is returned. This is repaid to the fund, by contributions from the surviving members.

To the widow of each member, who shall die after contributing fifteen years, an annuity of four pounds, by quarterly payments, from the member's death, during widowhood, for each share; and so in proportion for half a share, for which no other benefit had been received during the member's lifetime; and, if he leave no widow, the same annuity to be applied for the benefit of orphan children (if any) under twelve years of age, until the youngest of them attain that age.

To young children.—Any member, who wishes to make provision for a child or children, is allowed to enter any of them on the following terms:

If under four years of age when entered, the member pays four-pence monthly for each child, till it attains twelve years of age, if the member should live so long.

If four years, and under seven years, when entered, he pays three-pence monthly for each child.

If seven years, and under ten years, when entered, he pays two-pence monthly for each child.

If a member die and leave any child or children so contributed for, under twelve years of age, one shilling per week is applied out of the fund of the society, towards the maintenance

tenance of each such child, till it attains the age of twelve years; and, if the member choose to contribute double the above-mentioned sums for each child, the child or children will be entitled to double benefit: but no child is entitled to any benefit (excepting the annuity to be paid in case of the member's dying after contributing for fifteen years, *without leaving a widow*) unless entered and paid for twelve calendar months before the death of its father.

By purchasing cows.—A sum of money, not exceeding ten nor less than five pounds, is lent to any one member for this purpose; on his giving a promissory note, signed by himself and two householders (to be approved of by the steward, directors, and committee), for the repayment with interest by instalments, after the rate of two shillings a-week, or such other rate as may be agreed on.

By certificates.—Each member may obtain a certificate, as soon as admitted, which, by the act of parliament, will prevent him or her from being removed until actually chargeable; and, in cases of unmarried women having children in a parish to which they do not belong, the society's certificates will be a better security than many bonds of indemnity. Questions also of settlement may be decided without the removal of the certificated person, under the said act, 33d of Geo. III. ch. 54, sec. 21, 22.

The calculations for the contributions, &c. were formed upon Dr. Price's tables, making them, however, more in favour of old than young members; by which the funds are not injured, but rather the reverse, because young men are more inclined to subscribe than old; and, if the latter were to contribute according to the proportions of Dr. Price's tables, very few would become members. The composition table is lower also than Dr. Price's, notwithstanding which very few are found to avail themselves of the advantage.

The allowance in sickness is one-third higher than Dr. Price's; but members, who receive in sickness, are debarred from annuities for the same shares; and consequently this allowance in sickness may well be afforded.

In drawing the Castle-Eden tables, the object was to make the monthly contributions fully equal to the disbursements, and to induce persons of *all* ages under 46 to become members, without calculating exactly what each age ought to pay.

The preceding statement shews the accounts of the society, the gradation of its contributions, and the benefits derived by its members, in which the principal rules of the society may be traced. Little has been the amount of donations or subscriptions, and yet, during the severe trial of the late scarcity of bread-corn, few or none of the members omitted to keep up their subscriptions; testifying thereby an anxious and steady wish to provide permanently for themselves and families.

On the beneficial effects of an establishment so much in its infancy, we should be careful not to expatiate too much; but we may already ascertain some unquestionable advantages. The families of the poor have a more ready supply of medical assistance at their own houses; and, since they have been associated for each other's support, in more instances than one, they have collected little sums among themselves to present to their sick and necessitous neighbours, over and above the allowance from the funds of the society; which is probably an effect of philanthropy derived from the institution. All the members are uniformly anxious to avoid taking relief for sickness, during fifteen years, on their respective shares; a circumstance which, whilst it protects the fund, adds force to the habitual lesson of thrift; and, as there is a regular ledger kept in which each member's separate account is entered, no mistake can arise on that subject. The encouragement given to buying and keeping cows (see the article *COTTAGER*, *Supp.*) promises considerable improvement to the estate; as Mr. Burdon finds it very well worth his while, to accommodate the members with pasture for a cow, and two tons of hay each, for six pounds per annum. This, to a poor family, is a great advantage, and will tend much to diminish the weight of poor upon the parishes to which they belong. The locomotive faculty also derived from the certificates of friendly societies is a very obvious advantage.

The great desideratum, with respect to the maintenance of the poor, has always appeared to be the encouragement of habits of economy, and of a system of periodical subscription towards their own subsistence. Where men derive support in sickness and old age* from their individual efforts, in conjunction with those of their neighbours, they pass through the various periods of trial without that degradation, which attends parochial relief; being necessarily amenable to each other for a certain degree of forethought, and good conduct, they learn, insensibly, to be regular in their attention to the earnings of their business, and by acquiring a permanent connection with their neighbours, they become incapable of those acts of vagrancy, which are so wasteful of that main source of national wealth, the labour of the lower orders of the people.

Upon the whole, it is highly probable, that if the 33 Geo. III. chap. 54, for the encouragement of friendly societies, be allowed sufficient time to operate, the poor will, by degrees, be induced to take care of themselves, assisted by the contributions, and encouraged by the countenance, of their superiors.

In May, 1798, there was established at Winifon, in the county of Durham, in consequence of a suggestion of the Bishop of Durham, a friendly society for the aged poor; the object of which is to promote among them the due observance

* In a late instance, in the neighbourhood of Ealing, a majority, composed of the *young* men of a friendly society, agreed to dissolve the society, and divide the stock; and thereby at once defrauded all the *old* members of that provision for age and infirmity, which had been the object of many years' contribution. A new society was immediately formed of the young persons, and all the old members were left to the parish. This could not have happened, if *their rules had been regularly confirmed at the quarter sessions*.—The advantages of the rules being confirmed and registered (which by the act is to be without any fee or expence) are many and important;—their *bonds* are not chargeable with any *stamp duty*;—they have a copy of their rules on record, which they may always recur to;—if their steward or other person embezzles their money, they may apply to the court of chancery, and obtain a decree and *relief without any expence* whatever;—and in case any person, who has money or effects of the society in his hands, dies, or becomes a bankrupt, the debt of the society is to be discharged, *in preference to any other demand whatsoever*.—If all members of friendly societies had been aware, how much their security and benefit are increased by the confirmation of their rules, there would have been none but would have taken advantage of the act.—There is an unnecessary restriction in the statute law, as to the time for the confirmation of the rules of any friendly societies, established *before* the passing of that act. The benefits, however, of the act may be obtained (and there is an example in the publication mentioned in a preceding note) by the members *forming their society, and signing the rules anew*, with such amendments as occur; carrying their fund to the account of the new society, and giving to every member (instead of his divided share of the money) the same benefit in the fund of the new society, as he would have had in the old one.

of the sabbath, the study of the Scriptures, and of other good books, and also frugality and good neighbourhood.

For this purpose, they make a point of attending church on Sundays, not prevented by sickness, infirmity, or some unavoidable impediment; and also on other days, whenever they have opportunity: they likewise agree not to countenance any games or improper pastimes on a Sunday, by looking on, or sitting near them; and to use all the influence which they possess, to dissuade others from profaning the Lord's day:—they meet every Sunday evening at each other's houses, for religious improvement: and make it a general rule, to lay by every week something of their earnings, to accumulate till the end of the year; allotting however a tenth part thereof, and of the benefit they derive from the society, towards the relief of any of their necessitous neighbours, who (though not belonging to the society) should appear to merit their charitable assistance. They likewise agree to make it their business to do every thing that in them lies, to promote good-will, good-neighbourhood, and Christian charity, one amongst another.

The following are the rules of the society:

1. Any person may be a member of the society, who is sixty years of age or upwards.

2. Every subscriber of one penny per week, who is sixty years of age, or upwards, and under seventy, to be entitled to receive *double* his subscription, at the end of the year; that is, his own subscription, and as much more.

3. Every subscriber of one penny per week, who is forty years of age, or upwards, and under fourcore, to be entitled to receive *treble* his subscription at the end of the year; that is, his own subscription, and twice as much more.

4. Every subscriber of one penny per week, who is fourcore years of age, or upwards, and under ninety, to receive *four times* his subscription at the end of the year; that is, his own subscription, and three times as much more.

5. And to in proportion for every increase of ten years.

6. Any blind person, of any age, may be a member of the society, and, if under sixty years of age, will be entitled to the same benefit as subscribers who are sixty years of age, and under seventy.

7. Every member who absents himself from church on Sundays, except in case of sickness, or some unavoidable impediment, to forfeit his benefit upon the subscription of that week.

8. If any member of this society should die in the course of the year, his friends will be entitled to receive his subscription, and so much benefit as is proportioned to the time of subscribing.

9. Any person desirous of promoting the purposes of the society, without partaking of the benefit, may be an *honorary member*, by subscribing annually a guinea, or half a guinea, or not less than two pence per week; for which they will be entitled to receive weekly one copy of such publications as may be purchased for the use of the society.

10. The subscription to be paid at the time of the weekly meeting, to the member, at whose house the reading is held; to be delivered by him to the secretary, on the Monday following.

11. The annual subscription to be paid at the time of commencing member.

12. No members to receive any publication, whose subscription is in arrears.

13. No benefit member, who is in arrears, to receive any benefit till his arrears are paid.

This society consists of four honorary members (who subscribe an annual guinea each for the benefit of the fund), and nine old men and women, one of the age of 101 years, one a poor blind woman, and the other seven of ages between 60 and 80. The honorary member have it in their power, by

their weekly or annual subscription, not only to enlarge and improve the means of assisting the poorer members of the society, but at the same time to contribute to the amusement and instruction of their children and servants, and neighbours, by distributing among them the tracts of the Cheap Repository, and those of the Society for promoting Christian Knowledge, which are purchased for the use of the society.

The books which are selected for reading to them are, Orton's Discourses to the Aged,—Bishop Willon's Sermons,—Bishop Willon on the Sacrament,—Bishop Beveridge's Private Thoughts,—Flavell's Husbandry spiritualized, adapted to present use,—Christian Husbandry,—Fawcett's Religious Weaver,—Burder's Village Sermons,—and Peers's Companion for the Aged.

Of the origin of this society, the author lays, "I spoke to one of the old men, who had some turn for reading, and offered to come and read to him on the Sunday evening. The old man thanked me for the offer, and afterwards appeared much gratified with what I had done. I then told him that I would visit him the next Sunday evening; and that any other old persons among his neighbours, who wished it, might be present. A neighbour and his wife attended; and, on the Sunday after, other old persons came, in consequence of leave given them upon their application. Finding the Sunday readings gave pleasure to them, I made an offer of forming a regular society, on the terms before mentioned." This they gladly accepted, and have since expressed great satisfaction in this new employment of their Sunday evening.

There is a cheap but comfortable Sunday dinner provided, gratis, for all who attend church. It is prepared from one of the receipts in the first volume of the Society's Reports, the expence of it not exceeding three halfpence a-head. They dine at the house of one of the members, which from its situation is most convenient for the infirm members. The dinner is dressed at the rectory, and sent on the Saturday evening to the house where they dine.

The oldest and most infirm members are now become very punctual in their attendance on church; and by their example and influence, have contributed very much to the better observance of the sabbath at Winifon.

The Sunday readings were proposed, and the society which grew out of them, was established, in consequence of a suggestion in the Bishop of Durham's charge to the clergy of the diocese of Durham, in 1797, where the reader will find a strong recommendation of the establishment of societies of the poor for their religious improvement.

The institution of such societies appears to be susceptible of very extensive advantages. It supplies, by very practicable means, what was before wanting in the religious instruction of the poor. Sunday schools provide for the instruction of the young;—these societies will promote the edification and comfort of the old. The Sunday Friendly Society is founded on principles very favourable to religious and moral improvement, and to the cultivation of benevolence and philanthropy among the poor. It connects the aged poor in a friendly and Christian-like manner with their minister, and with one another. It brings into exercise a virtue, which is too often considered as out of the poor man's sphere; and as by it they not only receive charity, but become also the dispensers of it to others.

The allotment of their charitable tithe to the benefit of neighbours, who are *not* of their society, and the obliging of themselves by their *rules* to the observance of the duties of religion and benevolence, may be the means of gaining two great points in the cultivation of the heart;—one, a correction of the selfish principle; the other, a deliberate resolution of living and acting by rule and method. To the poor who cannot read at all,—to those who cannot afford to buy books,—

to those who are desirous of spiritual improvement, and of employing their latter days in a way the most conducive to the comfort of their last hours,—to the frugal, the neighbourly, and the benevolent, such an institution cannot fail to be very acceptable.

The value of religious societies, as helps to religious instruction and edification, has been long known to several sects of Christians. With them they have been the source of much useful instruction, and the means of keeping up a spirit of social and vital religion; and they contribute to aid the force of example, and therefore operate very beneficially on individual conduct. It would be happy for the cause of Christianity, if the friends of the established church would unite in following their example. Happy indeed would it be, if, at length, all contention between the denominations of Christians were reduced to an amicable rivalry, in the great work of saving souls;—in provoking one another to good works. In a word, if all our efforts, from however distant points they may originate, were to centre in a friendly competition in doing good.

To those who look with an anxious eye on the progress of the poor's rate, every institution that tends to encourage good conduct among the poor, must be the object of approbation; but those must be peculiarly so, which are calculated to afford relief to the elder and more infirm poor, by an annual charity, as a benefit upon *frugality* and good behaviour.

In forming a Sunday friendly society it is immaterial with how small a number the commencement is made; except, indeed, that there may be rather more advantages in beginning only with a few, and letting others find out the benefits of being members from conversation with those who are. The utmost that seems necessary (after two or three have agreed to meet together for reading the scriptures and other good books on Sunday evenings, and to bind themselves to a punctual observance of religious duties) is to distribute the rules of such society at some, or all, of the cottages in the parish.

It is a very desirable circumstance, that the meetings should be at the houses of the members by rotation; as it will not only be more satisfactory to them, but will conduce much to friendly intercourse and charitable communion. If the elderly poor in any town or village, should be too numerous to meet in one house, they may be divided into classes, and one or more of the members be employed as readers to the class, where the minister cannot attend regularly to more than one class.

The weekly penny should not be considered as a subscription, or condition of being admitted a member, but as a voluntary act of frugality. If they lay by their penny, and are not so regular as their rules require, they will still receive their own again; but it will be their own single talent unimproved. They may be members, if they please, without laying by their penny: as with to partake of the Sunday readings, and to join in a religious observance of the sabbath, is a sufficient qualification.

They may, possibly, be devout without being frugal; and yet frugality is so great a virtue in the poor, that it might be worth while to encourage and recommend to them the weekly deposit, as a means of benefiting themselves by the charitable disposition of their richer neighbours: a circumstance that will render the charity not only more useful than if it was merely gratuitous, but generally (it may be supposed) on that account more acceptable to them.

In large families and populous towns, the benefit upon the weekly savings might be in a great degree, if not wholly, raised from the contributions of the honorary members. In small parishes, the expence of the benefit will be inconsiderable: but even there, will be generally found some hono-

rary members, to share the expence with the landholder, and with the clergyman of the parish.

A society of a similar nature has been lately instituted at Bishops Auckland by the Bishop of Durham, who has the dinner provided for them, and supplies the extra fund, without the contribution of any honorary members. It confists at present, October, 1798, of 20 members; all (as there is reason to believe) gradually advancing to a more comfortable state of mind, and happy in their preparation for eternity. —In the formation of different societies, some difference in the detail may be occasioned by the circumstances of the place or the parties, but the general idea and the object will probably be the same.

FRIENDLY FEMALE-SOCIETIES, associations of the same nature as the foregoing, for the exclusive advantage of females. We select the following examples from the Reports of the London Society for bettering the Condition and increasing the Comforts of the Poor.

Among the many friendly societies which have been instituted by day-labourers in different parts of the country, an idea was adopted at Lymington, that something of this kind might be of great benefit to *distressed females*; and especially in that place, which being a little sea-port, and frequented by the flamen of small coasting vessels, and boatmen, their wives are often put to inconveniences by the misfortunes, and even by the absence of their husbands.

Mrs. Pierce, a lady of Lymington, took an active part in the business. Her first step was to consult among her friends, what support an institution of this kind was likely to receive; and soon found there was sufficient for the execution of her plan. Between thirty and forty inhabitants of Lymington, and its neighbourhood, were ready to subscribe each 14s. a-year, or 3d. a-week, which was all the assistance desired. A committee of ladies was then appointed to arrange the business; but Mrs. Pierce continued to be the most active member, by taking on herself the most troublesome office—that of treasurer.

On the 5th of April, 1790, the society was established. The regulations of it were chiefly these.—It was particularly intended for *lying-in* women, but was soon extended to the *sick of every denomination*. No one could enter as an object of this charity under the age of 15, nor above 50. It was required that she should be a parishioner, of good character, and in good health at the time of her entrance. On putting down her name she pays 6d. and three halfpence every week. Before she receives relief, her name must have been a year on the books; she is then entitled to 3s. a-week during any illness with which she may be visited: but she receives it only during the term of 13 weeks; if she is not then recovered, she receives 1s. a-week only, while it is thought necessary. Once a-year a charity sermon is preached, at which between 10l. and 16l. are generally collected. By this aid, and by great economy in the management of the fund, it has increased so much, that, instead of 3s. a-week, it already affords 4s. After the sermon, which is generally preached on the second Sunday in August, all the poor members who are able to go to church, walk in procession to the town-hall, with their patronesses at their head, who treat them with cake and wine. This is a pleasant day to them, and makes some return to the healthy, for not having had occasion to draw upon the fund for sickness. The grand murmur indeed against all these modes of relief, is, that they, who have had little occasion for them, think their money has been ill spent, though at the same time it is a fact, that most of the members of this society have at one time or other, received relief from it; not fewer in the whole than 65; of these 35 were women in child-bed. Two women have been

on the books, with lame hands, at s. s. a-week, for some years; and a third has been long relieved in a deep decline.

Indulgences are sometimes added, when personal misfortune is not to be pleaded. In the late scarcity of bread-corn, each poor member received a half-gallon loaf every Wednesday, for six weeks; and during the last two winters, each had three bushels of coals.—The society, at this time (June, 1798), consists of 55 poor members.

At TOTTENHAM High-Croft, a friendly society for the benefit of women and children was established on the 22d of October, 1798, under the respectable patronage of a number of ladies, who promised to support it with personal attendance, as well as pecuniary assistance.

Combined with the main design of this institution are two other objects; viz. a fund for loans, to prevent the sale of pawnbrokers' shops, and a bank for the earnings of poor children.

The principal rules are as follow:—the honorary members pay five shillings on entrance, and twelve shillings annually. The benefited members pay two shillings on entrance: they are divided into three classes, according to their age. The first class, which consists of those between twenty and thirty, pay six pence monthly. Those of the second class are between thirty and forty, and pay nine pence monthly. Those of the third class are between forty and fifty, and pay one shilling monthly.

No one is to contribute after sixty. From sixty-five to seventy, each member is to receive a pension of one shilling weekly; and from seventy to the end of their lives, two shillings weekly, even should they be obliged to retire into a workhouse. In case of sickness, four shillings weekly are allowed for four months in one year, and two shillings afterwards. And if a member dies, after having subscribed six years, thirty shillings are allowed for the funeral.

The honorary members, thinking themselves entitled to risk part of their own contributions, have authorised the stewardests, at their discretion, to lend small sums, from five shillings to thirty, to the benefited members on such occasions as they may approve. These loans are directed particularly to the enabling of them to purchase necessities at the wholesale price: or to supply themselves with articles for sale, materials for work, a pig, or any other thing, likely to produce a profit. These loans are repaid in small monthly payments.

Children of both sexes, of whatever age, whether belonging to a member or not, are permitted to bring any sum above one penny, to the monthly meeting of the stewardests, to be laid up in the fund of the society; where their small earnings may accumulate in security, till wanted for an apprentice fee, clothing on going to service, or some such important purpose; and in case of death, the sum laid up is returned to the parents of the child.

The business of the society is managed by six stewardests and a treasurer, who meet monthly. Four of the stewardests are chosen from the honorary members, and two from the benefited members. These offices are filled in alphabetical order at an annual meeting of the whole society. It should be added, that great attention is paid to the moral character, of those who are admitted members; and a notorious irregularity of conduct incurs expulsion.

In the formation of all charitable institutions, the increase

of virtue and happiness to society at large, should be considered as the great object of attainment; and the fundamental principle of action: an end which, it is presumed, the establishment in question is particularly adapted to promote, by the reciprocal advantages of rendering the affluent acquainted with the character and the moral conduct, the wants and the resources, of the indigent; whence they become better qualified to afford them judicious relief, and to distinguish between the deserving and the worthless.

The economy and the industry of the poor are encouraged by judicious loans, which enables them to buy articles of domestic consumption, and coals especially, on the most advantageous terms; or to provide materials for increasing their means of subsistence; as it is well known to those who are conversant with the affairs of the labouring classes, that it is much easier for them to spare a small sum at stated periods, than to lay down what is sufficient for either purpose at once.

Though the children receive no addition to the pittance they deposit in the fund, yet it answers several purposes.—It stimulates them to earn and save that which would probably be idly spent, as of too small importance for care; it often encourages their parents to lay by a little store for them, which they would not have thought of doing, had they not been invited by this opportunity of placing it in safety. It habituates the children to industry, frugality, and foresight; and, by introducing them to notice, it teaches the value of character, and of the esteem of those who, by the dispensations of Providence, are placed above them; and, in many instances, it may supply a resource, when it is essentially requisite.

The success has already succeeded expectation. Above sixty children bring their little treasure monthly; the benefited members repay their loans with great regularity; and there is a visible emulation to establish a good character by respectable conduct, and by a regard to propriety on the part of the poor; whilst kind attention, and active sympathy, are exerted on the part of the opulent.

At EMPINGHAM, near Stamford, in Rutlandshire, the following *female friendly society for girls* was established on the 1st of January, 1798; and sixteen girls were immediately admitted at the desire of their parents.

Female children, capable of spinning, knitting, or of any other profitable employ, which in that neighbourhood has been considerably increased by the Society of Industry there, subscribe to the general fund one halfpenny a-day out of their earnings. This is to be accumulated by compound interest, and to form a fund, out of which each subscriber, upon her marriage, is, after a contribution of fourteen years, entitled to receive two guineas; and, upon the birth of each child born in wedlock eight months or more after the expiration of the fourteen years' contribution, the like sum of two guineas.

Girls are not permitted to subscribe until seven years of age; and, if any girl dies under twenty-one, or before the expiration of the fourteen years of her subscription, the amount of her contribution, but without interest, is paid to her representatives at the expiration of the current half-year*; and if any subscriber, for fourteen years or upwards, continues unmarried till the age of fifty years, she is then entitled to two guineas a-year for life.

* It is submitted to consideration, whether it might not be better that there should be no repayment of the contribution in case of death: but that, instead of it, the period of contribution should be proportionately shortened; so as to entitle the subscriber to the donation, upon her marriage, after a contribution of ten or twelve (instead of fourteen) years.

An establishment of this nature is only adapted to those parts of England, in which the industry of the children of the poor has been, of late, so successfully and beneficially excited: it is more peculiarly applicable to places where schools of industry, with a cheap dinner for the children (see SCHOOL, Supp.), are established, as by Lord Winchelsea at Oakham, and by Mr. Conyers at Epping; for the mistresses may there, regularly and without any trouble, deduct the subscriptions from their weekly pay. The probable consequences of such female friendly societies are, that girls, so contributing out of their own earnings to a provision for their future life, will learn to set a higher value on their own characters, and will become examples of virtue and good conduct; and that, possessing the double advantage of a certain provisional assistance at periods when it is peculiarly wanted by the poor, and of habits of exertion and economy infensibly acquired during their youth, they will become objects of attention to all the well-disposed young men in the neighbourhood, and will be more likely to marry early, and to continue in a course of virtue and industry.

FRIESACH, a town of Germany, in the archbishopric of Saltzburg, with a strong castle, on a mountain, 56 miles S.E. of Saltzburg. Long. 14. 12. E. Lat. 47. 12. N.

FRINWALT, a town of Germany in the margravate of Brandenburg, seated on the Oder, 30 miles N.E. of Berlin. Long. 14. 10. E. Lat. 52. 50. N.

FRIO, CAPE, a promontory of Brasil, in the province of Rio Janeiro. Long. 41. 31. W. Lat. 92. 54. S.

FRISCH HAF, a long and narrow bay of the Baltic Sea, at the mouth of the Vistula.

FRISCHEN HAF, a bay of the Baltic Sea, at the mouth of the Oder. It lies between Stetin and the Baltic, with which it communicates by three mouths. See ODER.

FRITHELSTOKE, a village in Devonshire, two miles W. of Torrington, noted for the remains of its priory.

FRITZLAR, a town of Germany, in the landgravate of Hesse Cassel, 20 miles S.W. of Cassel.

FRULI, or CITTA DI FRULI, a town of Italy, in the province of Friuli, with a bishop's see, 32 miles N.N.W. of Trieste. Long. 13. 50. E. Lat. 46. 15. N.

FRODLINGHAM, a town in the E. riding of Yorkshire, with a market on Thursday, 36 miles E. of York, and 194 N. of London. Long. 0. 12. W. Lat. 53. 56. N.

FROG, in farriery, a part of a horse's foot, the form and purposes of which Mr. Coleman, Professor at the Veterinary College, describes in the following terms:

"The natural frog of the horse," says he, "is placed in the centre of the sole, externally convex, and of a wedge-like form, pointed towards the toe, but expanded as it advances to the heels. In the centre of the broad part there is a fissure, or separation. The frog is connected internally, with another frog, of a similar figure, but different in structure. The external frog is composed of soft elastic horn, and is totally insensible. The internal frog has sensation, and is much more elastic than the horny frog; and at the extremity of the heels is connected with two elastic substances called cartilages. The toe of the sensible frog is united to the coffin bone; but more than nine-tenths of both frogs are behind the coffin bone. The toe of the sensible and horny frogs, from their connection with the coffin bone, are fixed points, and have no motion; but the heels of the frogs being placed posterior to the coffin bone, and in contact with moveable, elastic (and not fixed or resisting) substances, a very considerable lever is formed, and whenever the horny frog comes in contact with the ground, it first ascends, and then descends. The pressure of the ground also expands the horny frog, and the sensible frog expands the cartilages, and at the heels

and quarters immediately below the hair, totally governs the direction of the future growth of the crust.

"This ascent of the frog, not only by its wedge-like form preserves the heels and quarters from contraction, but affords to the horse an elastic spring, and prevents the animal from slipping whenever it embraces the ground. Without any anatomical enquiry into its internal structure and union with other parts, the shape and convexity of the horny frog clearly demonstrates that it was formed to come into contact with the ground; and the more I investigate this subject, the more I am convinced that the use of the frog is to prevent the horse from slipping, to preserve the cartilages and hoof expanded, and, by its motion, to act as an elastic spring to the animal."

Mr. Coleman contends that Mr. St. Bel, and many others, who suppose that the use of the frog is merely to serve as a cushion, or guard, to the tendon of the flexor muscle of the foot, and who, on that account, were disposed rather to raise the frog from the ground, by a thick-heel'd shoe, have been in an error. On the contrary, he maintains it to be a law of nature, that unless the frog perform its functions, by being allowed to press the ground, it must become diseased. Accordingly the practice of shoeing very much depends on the functions of the frog being understood. "If the opinions here advanced respecting its uses, be well founded, then it must follow, that paring the frog and raising it from the ground annihilates its functions, and ultimately, if not immediately, produces disease; and that exposing the frog to pressure, is the only proper method to keep it in health. Moreover, it has from experience been ascertained, that unless the frog sustain a uniform pressure when at rest, the heels as well as the frog contract; but if that organ be in close contact with the ground, then it spreads and is free from thrushes and canker, and operates as a wedge to keep open the heels of the hoof."

"Granite and other hard substances, give no pain to a frog exposed to constant pressure in the stable; but when above the pavement, it generally becomes contracted, and the sensible frog inflamed, and then one stroke from a projecting stone, will produce pain, perhaps lameness, while perpetual perpendicular pressure is attended with salutary effects."

"When the hoof contracts, the frog must also become contracted, and inflammation and a suppurative follow, called a thrush. No contraction, however, takes place, where the frog is made to receive constant pressure, as the standing perpetually on that wedge increases its growth, presses upward the sensible frog, and expands the cartilages of the hoof. And as the first shoot of the crust at the coronet is very thin, the direction of its fibres will be altogether regulated by the width of the cartilages immediately below the hair at the quarters and heels, and the cartilages will be always more or less expanded, and the hoof more or less circular, as the frog has more or less pressure."

"On that principle," continues Mr. Coleman, "I long since recommended a shoe with thin heels, as the best formed shoe to bring the frog on the same level; and with great truth I can assert, that, although in some instances, from a sudden misapplication of the thin-heel'd shoe to improper feet, I have seen the tendons affected, yet from all the experience I have since had, and from all that I have seen or heard of the practice of others, I know of no instance where the frog, from constant pressure, did not expand and receive great benefit."

"Where the frog is in a morbid state, and unnaturally deprived of perpendicular pressure, it is seldom safe to lower the heels at once, so as to make the frog on a level with the shoe; and, in many cases, it is not possible, with any shoes, or even without shoes, to give the frog pressure on smooth surfaces;

much less is it practicable for the frog to rest on the ground when shod with common thick-heel'd shoes. In the stable, therefore, while at rest, the frog is generally raised above the shoe, and as pressure is essential to its health, particularly when the hoof is exposed to heat, it appeared to me of great importance, in all cases where the heels of the shoe and the frog cannot with safety be made on the same level, to apply an *artificial frog* (see Pl. 31.), to fit and give any degree of pressure, in the stable, to the natural frog, with any shoes. While the horse is in motion, and the hoof exposed to unequal surfaces, the artificial frog should be removed, as the natural frog, out of the stable, will receive frequent pressure with any shoes; but that period is of short duration, when compared to the length of time the horse remains at rest, and the frog raised from the ground.

"Artificial pressure is most particularly wanted when the heat of the stable operates powerfully to contract the hoof. In all cases, therefore, where the pavement of the stable does not touch the natural frog, an artificial frog is necessary to resist contraction of the hoof, thrushes, and canker. Sand-cracks, also, very generally arise from a contracted hoof, and may be prevented by the artificial frog.

"If the frog does not absolutely rest on the pavement, whatever shoes are employed, the hoof in the stable will be as much disposed to contract, as if the frog was raised any greater distance. I wish this fact to be well considered; for it has been supposed that shoes with a flat seat, without pressure to the frog, will prevent contraction. But I am fully convinced that neither thick nor thin heeled shoes, where the frog is raised above pressure, and exposed to the heat of the stable, can prevent contraction, or its effects; and where the frog receives that pressure, the heels cannot contract even with the most common shoes. For very obvious mechanical reasons, a wedge in the centre of the heels, aided by the pressure from below, must be best calculated to preserve them expanded, or when the heels are contracted, to force them open. The heat of the stable in all cases tends to contraction of the hoof; but with common shoes, there is no pressure on the wedge, or other cause to counteract that tendency. The artificial frog, which is intended to cover and give any degree of pressure to the natural frog only, is made of iron. In order to fit the natural frog, it is requisite to ascertain its width, the length of the foot, and the distance between the lower surface of the shoe and the frog. But if the artificial frog be too long, the toe, which is flat and thin, may be shortened; and if the heels of the shoe are higher than the artificial frog, nothing more is requisite than to introduce a quantity of tow between the natural and artificial frog, so as to raise it equal or above the level of the shoe. I have ascertained by experiment, that no inconvenience takes place by raising the artificial frog even one quarter of an inch above the shoe; but in ordinary cases, it should not project more than one-sixth of an inch above the surface of the shoe. It may, however, be imagined, that so much perpendicular pressure to the frog would retard rather than increase its growth. But the very reverse is the fact: for as the frog, when long elevated above the ground, is very generally contracted, this unnatural lateral pressure excites inflammation of the sensible frog, and deprives in a great degree the blood vessels of the power of secreting horn. When the horny frog is exposed to a perpendicular pressure, it gives health, and not disease, to the sensible frog. The blood vessels secrete their due proportion of elastic horn, and then the cavity of the frog is preserved, expanded, and fully equal to contain the sensible frog, without the smallest degree of lateral pressure.

"It therefore follows, that perpendicular pressure increases

the bulk of the frog; while its absence from the ground produces contraction, and lessens its growth."

The following is an explanation of the plate in which Mr. Coleman's PATENT ARTIFICIAL FROG is represented, with other figures that illustrate the subject.

Fig. 1, exhibits a view of the natural hoof of the horse, which is of a circular shape.

aaa The external surface of the sole of a concave form.

bbb The inferior edge of the crust.

cc The junction of the bars with the crust.

dd The points of the bars.

ee The sole between the heels of the crust and bars, the seat of corns.

ff Two cavities between the sides of the bars and the sides of the crust.

g The toe of the frog.

hh The heels of the frog.

ii The cleft between the heels of the frog, the seat of thrushes.

Fig. 2. A view of the hoof with contracted heels, occasioned by raising the frog above the pressure of the pavement in the stable.

aaa The sole.

bb The original seat of the bars, but improperly removed by the farrier.

cc The original seat of the cavities between the bars and crust, but now from contraction a solid horn.

dd The heels of the frog very much compressed, by the contraction of the hoof.

ee The width of the hoof at the heel, not being more than one half of the length from *f* to *g*.

f The extremity of the heels of the frog.

g The toe of the crust.

Fig. 3. The patent-frog, made of cast and wrought iron.

aa The lower surface opposite the ground, formed of cast-iron.

b An irregular cavity for the reception of the elastic spring, fig. 4.

c The toe of the patent frog, formed of wrought iron, to be occasionally shortened and adapted to the length of the foot, and placed under the toe of the shoe to confine the artificial frog from moving forwards.

dd A hole in the heels of the iron frog, for the passage of a strap, to buckle at the outside quarter or coronet.

Fig. 4. A flat steel spring, to fix the artificial frog in its place.

a An irregular projection, to be received into a corresponding concavity in the patent frog.

bb The ends of the spring, to be placed under the heels of the shoe opposite *cc* in fig. 1.

"The toe of the artificial frog is intended to be inserted under the toe of the shoe. This effectually fixes the frog forwards; and to prevent backward or lateral motion, an irregular groove is made in the iron frog, to receive a corresponding piece of steel, placed under the heels of the shoe. In general it is necessary to fix the frog more firmly, and, for that purpose, a hole is necessary, made in the heel of the artificial frog, to receive a strap, and to buckle at the outside quarter below the coronet. And that the artificial frog may give pressure in all cases with shoes thickened, or turned up for hunting or frost, a variety of frogs are made, to be adapted to particular feet and particular shoes. In cases of thrushes and canker of the frog, where no remedies without pressure are likely to be serviceable, an astringent thrush powder may be applied between the natural and artificial frog. And in contracted hoofs (or what has improperly been termed chest

foundered), where it may not be advisable to lower the heels equal with the horny frog, the artificial frog is essentially necessary. But indeed in every horse where the shoe and frog on a smooth surface are not on the same level, whatever shoes may be used, the iron frog in the stable should be applied; and in order to fix it with facility, the spring should first be laced under the shoe and brought backward to the heels of the hoof.

"The toe of the iron frog should then be inserted under the centre of the spring, and pushed as far as the toe of the shoe, while the other hand confines the spring until the centre of the spring meets the centre of the groove. The strap may then be buckled. And to dislodge the spring and iron frog, after the strap is unbuckled, nothing more is requisite than a small horse picker, introduced into a hole at the bottom of the groove of the iron frog; and the spring being raised above the groove and carried gently forward, the frog may be withdrawn from under the shoe without the smallest difficulty."

Mr. Coleman, in conclusion, wishes it to be clearly understood, "that in all cases where the frog and the heels of the shoe are placed on the same level, the patent frog is unnecessary. But where the frog is small, or the pattern joint long, or the action of the animal high, or the heels low, so as to render the application of thin-heeled shoes improper, or when the frog from any cause is raised above the ground in the stable, an artificial frog is useful in all such cases, and necessary to resist contraction of the hoof." To this equally ingenious and candid statement of Mr. Coleman, we are enabled to add our individual testimony as to the soundness of his reasoning, and the great practical utility of his *artificial frog*, which is now very generally adopted in the stables of persons of fashion in the united kingdom.

FRONSAC, a town of France, in the department of Gironde, seated on the Dordogne, 22 miles N.E. of Bourdeaux. Long. $0^{\circ} 16' W$. Lat. $45^{\circ} 5' N$.

FRONTEIRA, a town of Portugal, in Alentejo, 17 miles N.E. of Estremoz.

FROYEN, an island in the North Sea, near the coast of Norway, about 35 miles in circumference. Long. $9^{\circ} 0' E$. Lat. $63^{\circ} 45' N$.

FRUTINGEN, a town of Switzerland, in the canton of Bern, which gives name to a bailiwick, and is esteemed one of the most beautiful places in Switzerland. It is 30 miles S.E. of Friburg.

FUEL (*Encycl.*). The economy of fuel is an object of so much importance to the community at large, and more especially to the indigent members of it, that we are truly glad of this opportunity of laying before our readers the following observations relative to the Means of increasing the Quantities of Heat obtained in the Combustion of Fuel, by Count RUMFORD, from the Journals of the Royal Institution of Great Britain.

"It is a fact which has been long known," says the Count, "that clays, and several other incombustible substances, when mixed with sea coal, in certain proportions, cause the coal to give out more heat in its combustion than it can be made to produce when it is burnt pure or unmixed; but the cause of this increase of heat does not appear to have been yet investigated with that attention which so extraordinary and important a circumstance seems to demand.

"Daily experience teaches us that all bodies—those which are incombustible, as well as those which are combustible, and actually burning—throw off, in all directions, heat, or rather caloric (heat-making) rays, which generate heat wherever they are stopped, or absorbed; but common observa-

tion was hardly sufficient to shew any perceptible difference between the quantities of caloric rays thrown off by different bodies, when heated to the same temperature, or exposed in the same fire; although the quantities so thrown off might be, and probably are, very different.

"It has lately been ascertained, that when the sides and back of an open chimney fire-place, in which coals are burned, are composed of fire-bricks, and heated red-hot, they throw off into the room incomparably more heat than all the coals that could possibly be put into the grate, even supposing them to burn with the greatest possible degree of brightness. Hence it appears that a red-hot burning coal does not send off near so many caloric rays as a piece of red-hot brick or stone, of the same form and dimensions; and this interesting discovery will enable us to make very important improvements in the construction of our fire-places, and also in the management of our fires.

"The fuel, instead of being employed to heat the room directly, or by the direct rays from the fire, should be so disposed, or placed, as to heat the back and sides of the grate; which must always be constructed of fire-brick or fire-stone, and never of iron, or of any other metal. Few coals, therefore, when properly placed, make a much better fire than a large quantity; and shallow grates, when they are constructed of proper materials, throw more heat into a room, and with a much less consumption of fuel, than deep grates; for a large mass of coals in the grate arrests the rays which proceed from the back and sides of the grate, and prevents their coming into the room; or, as fires are generally managed, it prevents the back and sides of the grate from ever being sufficiently heated to assist much in heating the room, even though they be constructed of good materials, and large quantities of coals consumed in them.

"It is possible, however, by a simple contrivance, to make a good and an economical fire in almost any grate, though it would always be advisable to construct fire-places on good principles, or to improve them by judicious alterations, rather than to depend on the use of additional inventions for correcting their defects.

"To make a good fire in a bad grate, the bottom of the grate must be first covered with a single layer of balls, made of good fire-bricks, or artificial fire-stone, well burnt, each ball being perfectly globular, and about $2\frac{1}{2}$ or $2\frac{3}{4}$ inches in diameter. On this layer of balls the fire is to be kindled, and, in filling the grate, more balls are to be added with the coals that are laid on; care must, however, be taken in this operation to mix the coals and the balls well together, otherwise, if a number of the balls should get together in a heap, they will cool, not being kept red-hot by the combustion of the surrounding fuel, and the fire will appear dull in that part; but if no more than a due proportion of the balls are used, and if they are properly mixed with the coals, they will all, except it be those perhaps at the bottom of the grate, become red-hot, and the fire will not only be very beautiful, but it will send off a vast quantity of radiant heat into the room; and will continue to give out heat for a great length of time. It is the opinion of several persons who have for a considerable time practised this method of making their fires, that more than one-third of the fuel usually consumed may be saved by this simple contrivance. It is very probable that, with careful and judicious management, the saving would amount to one-half, or fifty per cent.

"As these balls, made in moulds, and burnt in a kiln, would cost very little, and as a set of them would last a long time—probably several years—the saving of expence in heating rooms by chimney fires, with bad grates in this way, is

Fig. 1.

A Constructed Foot.

Fig. 2.

A Perfect Foot.

Fig. 1.

Fig. 3.

obvious; but still it should be remembered, that a saving quite as great may be made by altering the grate, and making it a good fire-place.

"In using these balls, care must be taken to prevent their accumulating at the bottom of the grate: as the coals go on to consume, the balls mixed with them will naturally settle down towards the bottom of the grate, and the tongs must be used occasionally to lift them up; and, as the fire grows low, it will be proper to remove a part of them, and not to replace them in the grate till more coals are introduced—a little experience will then how a fire made in this manner can be managed to the greatest advantage, and with the least trouble.

"Balls, made of pieces of any kind of well-burnt hard brick, though not equally durable with fire-brick, will answer very well, provided they be made perfectly round; but if they are not quite globular their flat sides will get together, and, by obstructing the free passage of the air amongst the coals, will prevent the fire from burning clear and bright.

"The best composition for making these balls, when they are formed in moulds, and afterwards dried and burnt in a kiln, is pounded crucibles mixed up with moistened Sturbridge clay; but good balls may be made with any very hard burnt common bricks, reduced to a coarse powder, and mixed with Sturbridge clay, or even with common clay. The balls should always be made to large as not to pass through between the front bars of a grate.

"These balls have one advantage, which is peculiar to them, and which might perhaps recommend the use of them to the curious, even in fire-places constructed on the best principles; they cause the cinders to be almost consumed entirely; and even the very ashes may be burnt, or made to disappear, if care be taken to throw them repeatedly upon the fire when it burns with an intense heat. It is not difficult to account for this effect in a satisfactory manner; and in accounting for it we shall explain a circumstance on which it is probable that the great increase of the heat of an open fire, where these balls are used, may, in some measure, depend. The small particles of coal, and of cinder, which, in a common fire, fall through the bottom of the grate, and escape combustion, when these balls are used can hardly fail to fall and lodge on some of them; and, as they are intensely hot, these small bodies, which alight upon them in their fall, are soon heated red-hot, and disposed to take fire and burn; and as fresh air from below the grate is continually making its way upwards amongst the balls, every circumstance is highly favourable to the rapid and complete combustion of these small inflammable bodies. But if these small pieces of coal and cinder should, in their fall, happen to light upon the metallic bars which form the bottom of the grate—as these bars are conductors of heat, and, on account of that circumstance, as well as of their situation—below the fire—never can be made very hot—any small particle of fuel that happens to come into contact with them, not only cannot take fire, but would cease to burn should it arrive in a state of actual combustion.

"These facts are very important, and well deserving of the attention of those who may derive advantage from the improvement of fire-places, and the economy of fuel.

"There are some circumstances which strongly indicate that an admixture of incombustible bodies with fuel, and especially with coal, cause an increase of the heat, even when the fuel is burnt in a closed fire-place. No fire-place can well be contrived more completely closed than those of the iron stoves in common use in the Netherlands; but, in these stoves—which are heated by coal fires—a large proportion of wet clay is always coarsely mixed with the coal before they are introduced into the fire-place. If this practice had not been

found to be useful, it would certainly never have been obtained generally; nor would it have been continued, as it has been, for more than two hundred years.

"The combination of different substances, combustible and incombustible, to form, artificially, various kinds of cheap and pleasant fuel, particularly adapted for the different processes in which the fuel is employed, is a subject well worthy the attention of enterprising and ingenious men. How much excellent fuel, for instance, might be made with proper additions, and proper management, of the mountains of refuse coal-dust that lie useless at the mouths of coal-pits; and how much would it contribute to cleanliness and elegance, if the use of improved coke, or of hard and light fire-balls, could be generally introduced in our houses and kitchens, instead of crude, black, powdery, dirty sea-coal? Of the great economy that would result from such a change there cannot be the smallest doubt.

"It is a melancholy truth, but, at the same time, a most undisputable fact, that, while the industry and ingenuity of millions are employed, with unceasing activity, in inventing, improving, and varying those superfluities which wealth and luxury introduce into society, no attention whatever is paid to the improvement of those common necessities of life on which the subsistence of all, and the comforts and enjoyments of the great majority of mankind, absolutely depend.

"Much will be done for the benefit of society," adds this truly patriotic philosopher, "if means can be devised to call the attention of the active and benevolent to this long-neglected, but most interesting subject." Till this, however, is effectually done, we think it of consequence to shew what has been attempted in certain parts of the kingdom by way of supplying the poor with fuel, and instructing them in the economical and beneficial use of it. The following is an extract from an account of a provision made upon an inclosure, for supplying the poor with fuel, by Edward Parry, Esq.

"Upon the inclosure of the parish of Little Dunham in the county of Norfolk, in the year 1794," says Mr. Parry, "being lord of the manor, I got a clause inserted, directing the commissioners to set out a parcel of land, to be called 'the poor's estate,' and to be vested in the lord of the manor, rector, churchwardens, and overseers of the poor for the time being, and to be let by them for 21 years on lease; the rents and profits to be laid out by them on fuel, to be delivered at the cottages of the poor, in such proportions as the trustees should think proper.

"Although the prejudices of the poor, against the inclosure, were very great before it took place, the moment they saw the land inclosed, and let as the poor's estate for 21 years by auction, at the rate of 50s. a-year (although only estimated by the commissioners at 20l. a-year), they were highly gratified; and they have indeed great reason to rejoice, being now most amply supplied with that great comfort of life. This has been to apparent, that some neighbouring inclosures have followed the example, and it appears to me advisable, that such a plan should be generally made known.

"The first idea was to sell the land, and place the money in the public funds, in order to produce a larger income; but I found that was not understood by the poor: they said, they might at any time be deprived of the money, and they had no interest in the land inclosed; whereas, in the mode pursued, they considered themselves as having a permanent and improveable estate, which their children would inherit. These prejudices are valuable; as in their consequences they produce, if attended to, industry and content.

"I have had occasion to observe as to fuel, which is certainly an important article to the poor, that, where there are commons, the ideal advantage of cutting flags, peat, or

whins, often causes a poor man to spend more time in procuring such fuel, than, if he reckoned his labour, would purchase for him double that quantity of good firing."

An account of a provision of fuel for the poor at Lower Winchendon, by Scrope Bernard, esq. appears, with the foregoing, in the Reports of the Society for bettering the Condition of the Poor, &c.

"There having been," says Mr. Bernard, "several prosecutions at the Aylesbury quarter sessions, for stealing fuel last winter, I was led to make some particular enquiries, respecting the means which the poor at Lower Winchendon had of providing fuel. I found that there was no fuel then to be sold within several miles of the place; and that, amid the distress occasioned by the long frost, a party of cottagers had joined in hiring a person, to fetch a load of pit-coal from Oxford, for their supply. In order to encourage this disposition to acquire fuel in an honest manner, and to induce the poor to burn coal instead of wood, in a country very bare of the latter article, a present was made to all this party (eight families in number) of as much more coal as they had purchased, and the carriage of the like quantity was further allowed them free of expence.—Having no grates, they had employed the village blacksmith to tack together a few iron bars by an iron rim at each end, which when raised above the hearth by loose bricks, enabled them to keep up a good fire. I went to see one of those grates: it was a foot square, quite flat, and had been made out of an old scythe by the blacksmith, at the expence of one shilling.—In this manner some of the poorest families in the village got through the last hard winter. But they complained of the want of faggots to light their fires, which were not to be obtained by honest means. To remedy this, against the next winter, I had three waggon loads of the small faggots called kindlers, made up from a fall of beechwood, in the Chiltern country, ten miles off, and brought to Winchendon in the summer season. And as, in September, from the state of the harvest, it was foreseen that it would be a trying winter for the poor, a vestry was called, and it was proposed to them, as one mode of relief, that they should allow the poor the carriage of a limited portion of coal; which was then sold at 1s. 4d. the hundred, at the Oxford wharf. At the same time they were informed that eleven hundred faggots were provided out of the Chiltern woods, as kindlers, to assist such a plan; which it was intended to sell, much under the real value, at a penny a piece. This plan was agreed to, and the necessary quantity ordered to be fetched at the charge of the parish. A few tons were fetched before the frost set in, and were distributed at 1s. 4d. per hundred weight, with three kindlers to every hundred weight of coals, by a person residing in the centre of the parish; each family applying took a moderate quantity, such as might be supposed to contribute to their comfort, without trenching on their means of subsistence. The price of coals at Oxford had in the interim risen beyond what is here stated; but no alteration was made in the retail price on that account; the increase being defrayed out of a donation, which had been made at Christmas, applicable to this charity. The expence of distribution, at 10d. per ton, was also paid

out of the same fund. It had been said that the poor would not find money to purchase them, when they were brought: instead of which, out of 35 poor families belonging to the parish, 29 came with ready money, hufbanded out of their scanty means, to profit with eagerness of this attention to their wants; and among them a person who had been lately imprisoned by his master for stealing wood from his hedges. The six, who did not purchase, were, as I learnt upon inquiry, prevented by some particular circumstances, which rendered the supply unnecessary.

"In this manner 29 poor families, consisting of 110 poor persons, are supplied during the present season with fuel, at an expence to the parish, aided by voluntary charity, of about three guineas per month; being the charge for carriage, distribution, and occasional excess of price: the average wharf price of the article, which for the same period was less than five guineas, being paid by the poor themselves, with thankfulness for the advantage which they derived from this mode of purchase.

"I have been the more particular in this detail, because it exhibits, though on a small scale, an instance of uniting parish relief with private subscription, so as to lighten the weight of both; and I think it may sometimes be convenient that they should go hand in hand. At Whitechurch, in this county, the same kind of charity was established last winter. It now continues by a private subscription of between 17l. and 20l. for that object, during the season: but one or two of the most opulent declined contributing; and though disburthened of a part of the expence of the poor, shrunk from the duty of aiding such a plan, because it was voluntary.—In order therefore to prevent the covetous from entirely eluding, it seems to be better, where it can be adopted as the unanimous act of the parish, or where the manner of doing it can be made consistent with the poor laws, that the foundation should be laid by the parish in an allowance, as far as they think proper to go; and that the voluntary charity of individuals should be grafted on that stock, for the purpose of effecting a further reduction of the price.

"I have often wished to bring coal into general use at Winchendon; the poor however being jealous of any schemes, under the impression that they are more calculated for the benefit of others, than of themselves, and the farmer not being very fond of new expences, I had judged the attempt to be vain. But the circumstances above recited having led both parties to make a trial, I believe that the one finds a great addition of comfort, and the other no great increase of expence.

"The attempt to introduce proper chimneys into cottages in this neighbourhood, instead of the present spacious and airy ones with seats in the corner, has met with constant resistance; nor is it to be expected that any impression will be made on the poor inhabitants, till they have had full opportunity of ascertaining, by observation and experience, the comforts and advantages of chimneys on a different construction. In the hope of effecting this change in their opinions, two cottage chimneys, on Count Rumford's * principles, are now building in this village.

* It is rather unfortunate for the public that the *pretended improvements of Count Rumford's grates*, so pompously announced by different ironmongers, are chiefly calculated to increase the expence, and to diminish the effect, of his useful invention. When the reader visits the Royal Institution, he will see that the new grates put up there are very cheap, and have as little iron as possible about them, and that *the fire always burns against fire bricks*: the back and sides of the grate being composed of brick, which throws out heat in greater quantity, and is not subject to the disagreeable smell and bad effects of heated iron. In those shops where *these improvements are carried on to the greatest perfection*, they will find nothing left of the benefit of Count Rumford's original invention, except the narrow throat to the chimney; and even that is not always preserved. The distinguishing features are—an abundance of polished steel,—as much iron as can be used on every side of the fire,—and a very liberal accumulation of expence.

"If we wish effectually to prevent the poor from stealing wood, and from similar acts of theft, it should be our first aim to put it perfectly in their power to obtain on fair terms the articles necessary to their existence. When the means of life and the acquisition of food and fuel are beyond the attainment of the industrious labourer, the inducement to guilt, and to invading the store of his neighbour, become so powerful, as to put the virtue and integrity of the poor man to a very severe trial.—Persons enjoying the superior advantages of education, with minds formed to habits of honour and virtue, may feel confident in their own powers of forbearance, even under such circumstances: but it will not follow that it is either wise, or just, to expose the cottager to so great a temptation. Where the option is not given them of acquiring in an honest manner, and in exchange for the produce of their labour, the indispensable necessities of existence (and such is fuel in this northern climate), however we may condemn any crime which may follow, we have no great reason to be surprised at such a result; nor perhaps ought we to consider ourselves as entirely exempt from a share in the guilt."

FUEN-TCHEOU-FOU, a commercial city of China, in the province of Chang-fi. Its baths and springs, almost as hot as boiling water, attract a great number of strangers. Its district contains one city of the second, and seven of the third class. It is seated on the Fuen-ho, 250 miles S.W. of Peking.

FUENTE DUEGNA, a town of Spain, in New Castile, seated on the Tajo, 35 miles S.E. of Madrid. Long. 3.0. W. Lat. 40. 14. N.

FUENTE GINALDO, a town of Spain, in Estremadura. In 1734 it was taken and plundered by the Portuguese, under the marquis das Minhas. It is 16 miles N.W. of Coria.

FUESEN, a town of Suabia, belonging to the bishop of Augsburg, with an ancient castle. It is seated on the Leech, 50 miles S. by E. of Augsburg. Long. 11. 25. E. Lat. 47. 40. N.

FULIDENTALL, a town of Silesia, in the duchy of Troppaw, taken by the king of Prussia in 1741 and 1744. It is seated near the Mohra, 16 miles W. by S. of Troppaw.

FULA, or THULE, one of the Shetland Islands, W. of Mainland. It is thought by some to be the same which the ancients reckoned the ultimate limit of the habitable globe, and to which, therefore, they gave the appellation of ultima Thule. It is doubtful, however, whether this be really the island so called; because, had the ancients reached it, they must have seen land still further to the N.E.; Mainland, Yell, and Unst, being all further N.

FULMINATION (*Encycl.*). Under the head of DETONATION, &c. we have given an account of the substances heretofore known to produce this extraordinary effect. We shall here add the highly curious Observations on a new fulminating Mercury, by EDWARD HOWARD, Esq. F.R.S. published in the Transactions of the Royal Society of London.

I. The mercurial preparations which fulminate, when mixed with sulphur, and gradually exposed to a gentle heat, are well known to chemists: they were discovered, and have been fully described, by Mr. Bayen*.

"MM. Brugnatelli and Van Mons have likewise produced fulminations by concussion, as well by nitrate of mercury and phosphorus as with phosphorus and most other nitrates†.

Cinnabar likewise is amongst the substances which, according to MM. Fourcroy and Vauquelin, detonate by concussion with oxymuriate of potash‡.

"Mr. Ameillon had, according to Mr. Berthollet, observed, that the precipitate obtained from nitrate of mercury, by oxalic acid, fuses with a hissing noise§.

II. "But mercury, and most if not all its oxides, may, by treatment with nitric acid and alcohol, be converted into a whitish crystallized powder, possessing all the inflammable properties of gun-powder, as well as many peculiar to itself.

"I was led to this discovery by a late assertion, that hydrogen is the basis of the muriatic acid; it induced me to attempt to combine different substances with hydrogen and oxygen. With this view I mixed such substances with alcohol and nitric acid as might (by predispounding affinity) favour as well as attract an acid combination of the hydrogen of the one, and the oxygen of the other. The pure red oxide of mercury appeared not unfit for this purpose; it was therefore intermixed with alcohol, and upon both, nitric acid was affused. The acid did not act upon the alcohol so immediately as when these fluids are alone mixed together, but first gradually dissolved the oxide; however, after some minutes had elapsed, a smell of ether was perceptible, and a white dense smoke, much resembling that from the *liquor fumans* of LIBAVIUS, was emitted with ebullition. The mixture then threw down a dark coloured precipitate, which by degrees became nearly white. This precipitate I separated by filtration; and, observing it to be crystallized in smaller acicular crystals, of a saline taste, and also finding a part of the mercury volatilized in the white fumes, I must acknowledge I was not altogether without hopes that muriatic acid had been formed, and united to the mercurial oxide; I therefore, for obvious reasons, poured sulphuric acid upon the dried crystalline mass, when a violent effervescence ensued, and, to my great astonishment, an explosion took place. The singularity of this explosion induced me to repeat the process several times; and finding that I always obtained the same kind of powder, I prepared a quantity of it, and was led to make the series of experiments which I shall have the honour to relate in this paper.

III. "I first attempted to make the mercurial powder fulminate by concussion; and for that purpose laid about a grain of it upon a cold anvil, and struck it with a hammer, likewise cold: it detonated slightly, not being, as I suppose, struck with a flat blow; for, upon using three or four grains, a very stunning disagreeable noise was produced, and the faces both of the hammer and the anvil were much indented.

"Half a grain, or a grain, if quite dry, is as much as ought to be used on such an occasion.

"The shock of an electrical battery, sent through five or six grains of the powder, produces a very similar effect: it seems, indeed, that a strong electrical shock generally acts on fulminating substances like the blow of a hammer. Messrs. Fourcroy and Vauquelin found this to be the case with all their mixtures of oxymuriate of potash.

"To ascertain at what temperature the mercurial powder explodes, two or three grains of it were floated on oil, in a capsule of leaf tin; the bulb of a Fahrenheit's thermometer was made just to touch the surface of the oil, which was then gradually heated till the powder exploded, as the mercury of the thermometer reached the 368th degree.

§ This fact has been misrepresented in the introduction to a work entitled, The chemical Principles of the metallic Arts, by W. Richardson, Surgeon, F.A.S. page 57.

IV. "Desirous of comparing the strength of the mercurial compound with that of gunpowder, I made the following experiment in the presence of my friend Mr. Abernethy.

"Finding that the powder could be fired by flint and steel, without a disagreeable noise, a common gunpowder proof, capable of containing eleven grains of fine gunpowder, was filled with it, and fired in the usual way: the report was sharp, but not loud. The person who held the instrument in his hand felt no recoil; but the explosion laid open the upper part of the barrel, nearly from the touch-hole to the muzzle, and struck off the hand of the register, the surface of which was evenly indented, to the depth of $\frac{1}{8}$ of an inch, as if it had received the impression of a punch.

"The instrument used in this experiment being familiarly known, it is therefore scarcely necessary to describe it: suffice it to say, that it was of brass, mounted with a spring-register, the moveable hand of which closed up the muzzle, to receive and graduate the violence of the explosion. The barrel was half an inch in caliber, and nearly half an inch thick, except where a spring of the lock impaired half its thickness.

V. "A gun, belonging to Mr. Keir, an ingenious artist of Camden-Town, was next charged with 17 grains of the mercurial powder, and a leaden bullet. A block of wood was placed at about eight yards from the muzzle, to receive the ball, and the gun was fired by a fuse. No recoil seemed to have taken place, as the barrel was not moved from its position, although it was in no ways confined. The report was feeble: the bullet, Mr. Keir conceived, from the impression made upon the wood, had been projected with about half the force it would have been by an ordinary charge, or 68 grains, of the best gunpowder. We therefore re-charged the gun with 34 grains of the mercurial powder; and, as the great strength of the piece removed any apprehension of danger, Mr. Keir fired it from his shoulder, aiming at the same block of wood. The report was like the first in section four, sharp, but not louder than might have been expected from a charge of gunpowder. Fortunately Mr. Keir was not hurt, but the gun was burst in an extraordinary manner. The breech was what is called a patent one, of the best forged iron, consisting of a chamber, $\frac{1}{4}$ of an inch thick all round, and $\frac{1}{4}$ of an inch in caliber; it was torn open and flamed in many directions, and the gold touch-hole driven out. The barrel, into which the breech was screwed, was $\frac{1}{2}$ of an inch thick; it was split by a single crack three inches long, but this did not appear to me to be the immediate effect of the explosion. I think the screw of the breech, being suddenly enlarged, acted as a wedge upon the barrel. The ball missed the block of wood, and struck against a wall, which had already been the receptacle of so many bullets, that we could not satisfy ourselves about the impression made by this last.

VI. "As it was pretty plain that no gun could confine a quantity of the mercurial powder sufficient to project a bullet, with a greater force than an ordinary charge of gunpowder, I determined to try its comparative strength in another way.—I procured two blocks of wood, very nearly of the same size and strength, and bored them with the same instrument to the same depth. The one was charged with half an ounce of the best Dartford gunpowder, and the other with half an ounce of the mercurial powder; both were alike buried in sand, and fired by a train communicating with the powders by a small touch-hole. The block containing the gunpowder was simply split into three pieces: that charged with the mercurial powder was burst in every direction, and the parts immediately contiguous to the powder were absolutely pounded, yet the whole hung together, whereas the block split by the gunpowder had its parts fairly separated. The sand surrounding the gunpowder was undoubtedly most disturbed; in short, the mer-

curial powder appeared to have acted with the greatest energy, but only within certain limits.

VII. "The effects of the mercurial powder, in the last experiments, made me believe that it might be confined, during its explosion, in the centre of a hollow glass globe. Having therefore provided such a vessel, seven inches in diameter, and nearly half an inch thick, mounted with brass caps, and a stop-cock (see plate 32.); I placed ten grains of the mercurial powder on very thin paper, laid on iron wire, 149th of an inch thick, across the paper, through the midst of the powder, and, closing the paper, tied it fast at both extremities, with silk, to the wire. As the inclosed powder was now attached to the middle of the wire, each end of which was connected with the brass caps, the packet of powder became, by this disposition, fixed in the centre of the globe. Such a charge of an electrical battery was then sent along the wire, as a preliminary experiment (with Mr. Cuthbertson's electrometer) had shewn me would, by making the wire red hot, inflame the powder. The glass globe withstood the explosion, and of course retained whatever gases were generated; its interior was thinly coated with quicksilver, in a very divided state. A bent glass tube was now screwed to the stop-cock of the brass cap, which being introduced under a glass jar standing in the mercurial bath, the stop-cock was opened. Three cubical inches of air rushed out, and a fourth was set at liberty when the apparatus was removed to the water tub. The explosion being repeated, and the air all received over water, the quantity did not vary. To avoid an error from change of temperature, the glass globe was, both before and after the explosion, immersed in water of the same temperature. It appears therefore, that the ten grains of powder produced four cubical inches only of air.

"To continue the comparison between the mercurial powder and gunpowder, 10 grains of the best Dartford gunpowder were in a similar manner set fire to in the glass globe: it remained entire. The whole of the powder did not explode, for some complete grains were to be observed adhering to the interior surface of the glass. Little need be said of the nature of the gases generated during the combustion of the gunpowder: they must have been, carbonic acid gas, sulphureous acid gas, nitrogen gas, and (according to Lavoisier) perhaps hydrogen gas. As to the quantity of these, it is obvious that it could not be ascertained; because the two first were, at least in part, speedily absorbed by the alkali of the nitre, left pure after the decomposition of its nitric acid."

The following are the references to the figures of the glass globe, &c. in pl. 32.

A, is a ball or globe of glass, nearly half an inch thick, and seven inches in diameter. It has two necks, on which are cemented the brass caps B, C, each being perforated with a female screw, to receive the male ones D, E; through the former a small hole is drilled; the latter is furnished with a perforated stud or shank G. By means of a leather collar H, the neck C can be air-tightly closed. When a portion of the powder is to be exploded, it must be placed on a piece of paper, and a small wire laid across the paper, through the midst of the powder; the paper being then closed, is to be tied at each end to the wire, with a silken thread, as shewn at I. One end of this wire is to be fastened to the end of the shank G, and the screw D inserted to half its length into the brass cap B; the other end of the wire a, by means of the needle K, is to be drawn through the hole F. The screw E being now fixed in its place, and the wire drawn tight, is to be secured by pushing the irregular wooden plug L into the aperture of the screw D, taking care to leave a passage for the air. The stop-cock M, the section of which is at N, is now to be screwed on the part D, which is made air-tight by the leather collar b. The glass tube O is

bent, that it may more conveniently be introduced under the receiver of a pneumatic apparatus. P. shews the manner of connecting the glass tube with the stop-cock.

VIII. "From the experiments related in the fourth and fifth sections, in which the gunpowder proof and the gun were burst, it might be inferred, that the astonishing force of the mercurial powder is to be attributed to the rapidity of its combustion; and a train of several inches in length being consumed in a single flash, it is evident that its combustion must be rapid. From the experiments of the sixth and seventh sections, it is sufficiently plain that this force is restrained to a narrow limit, both because the block of wood charged with the mercurial powder was more shattered than that charged with the gunpowder, whilst the sand surrounding it was least disturbed, and likewise because the glass globe withstood the explosion of 10 grains of the powder fixed in its centre; a charge I have twice found sufficient to destroy old pistol barrels, which were not injured by being fired when full of the best gunpowder. It also appears from the last experiment, that 10 grains of the powder produced by ignition four cubical inches only of air; and it is not to be supposed that the generation, however rapid, of four cubical inches of air, will alone account for the described force; neither can it be accounted for by the formation of a little water, which, as will hereafter be shewn, happens at the same moment; the quantity formed from 10 grains must be so trifling, that I cannot ascribe much force to the expansion of its vapour. The sudden vaporization of a part of the mercury seems to me a principal cause of this immense yet limited force; because its limitation may then be explained, as it is well known that mercury easily parts with caloric, and requires a temperature of 600 degrees of Fahrenheit, to be maintained in the vaporous state. That the mercury is really converted into vapour, by ignition of the powder, may be inferred from the thin coat of divided quicksilver, which, after the explosion in the glass globe, covered its interior surface; and likewise from the quicksilver with which a tallow candle, or a piece of gold, may be evenly coated, by being held at a small distance from the inflamed powder. These facts certainly render it more than probable, although they do not demonstrate, that the mercury is volatilized; because it is not unlikely that many mercurial particles are mechanically impelled against the surface of the glass, the gold, and the tallow.

"As to the force of the dilated mercury, Mr. Baumé relates a remarkable instance of it, as follows:

"Un alchimiste se présenta à Mr. Geoffroy, et l'assura qu'il avoit trouvé le moyen de fixer le mercure par une opération fort simple. Il fit construire six boîtes rondes en fer fort épaies, qui entroient les unes dans les autres; la dernière étoit assujettie par deux cercles de fer qui se croisoient en angles droits. On avoit mis quelques livres de mercure dans la capacité de la première: on mit cet appareil dans un fourneau assez rempli de charbon pour faire rougir à blanc les boîtes de fer; mais, lorsque la chaleur eut pénétré suffisamment le mercure, les boîtes crèvent, avec une telle explosion qu'il se fit un bruit épouvantable: des morceaux de boîtes furent lancés avec tant de rapidité qu'il y en eut qui passèrent au travers de deux planchers; d'autres firent sur la muraille des effets semblables à ceux des éclats de bombes."

"Had the alchemist proposed to fix water by the same apparatus, the nest of boxes must, I suppose, have likewise been ruptured; yet it does not follow that the explosion would have been so tremendous: indeed, it is probable that it would not, for if (as Mr. Kirwan remarked to me) substances which have

the greatest specific gravity have likewise the greatest attraction of cohesion, the supposition that the vapour of mercury exceeds in expansive force the vapour of water, would agree with a position of Sir Isaac Newton, that those particles recede from one another with the greatest force, and are most difficultly brought together, which upon contact cohere most strongly.

IX. "Before I attempt to investigate the constituent principles of this powder, it will be proper to describe the process and manipulations which, from frequent trials, seem to be best calculated to produce it. 100 grains, or a greater proportional quantity, of quicksilver (not exceeding 500 grains), are to be dissolved, with heat, in a measured ounce and a half of nitric acid. This solution being poured cold upon two measured ounces of alcohol, previously introduced into any convenient glass vessel, a moderate heat is to be applied until an effervescence is excited. A white fume then begins to undulate on the surface of the liquor; and the powder will be gradually precipitated, upon the cessation of action and re-action. The precipitate is to be immediately collected on a filter, well washed with distilled water, and carefully dried in a heat not much exceeding that of a water-bath. The immediate edulcoration of the powder is material, because it is liable to the re-action of nitric acid; and, whilst any of that acid adheres to it, it is very subject to the influence of light. Let it also be cautiously remembered, that the mercurial solution is to be poured upon the alcohol.

"I have recommended quicksilver to be used in preference to an oxyd, because it seems to answer equally, and is less expensive; otherwise, not only the pure red oxyd, but the red nitrous oxyd, and turpeth, may be substituted; neither does it seem essential to attend to the precise specific gravity of the acid, or the alcohol. The rectified spirit of wine, and the nitrous acid of commerce, never failed, with me, to produce a fulminating mercury. It is indeed true, that the powder prepared without attention is produced in different quantities, varies in colour, and probably in strength. From analogy, I am disposed to think the whitest is the strongest; for it is well known, that black precipitates of mercury approach the nearest to the metallic state. The variation in quantity is remarkable; the smallest quantity I ever obtained from 100 grains of quicksilver being 120 grains, and the largest 132 grains. Much depends on very minute circumstances. The greatest product seems to be obtained when a vessel is used which condenses and causes most ether to return into the mother liquor; besides which, care is to be had in applying the requisite heat, that a speedy, and not a violent action, be effected. 100 grains of an oxyd are not so productive as 100 grains of quicksilver.

"As to the colour, it seems to incline to black when the action of the acid on the alcohol is most violent, and *vice versa*.

X. "I need not observe, that the gases which were generated during the combustion of the powder in the glass globe, were necessarily mixed with atmospheric air; the facility with which the electric fluid passes through a vacuum, made such a mixture unavoidable.

"The cubical inch of gas received over water was not readily absorbed by it; and, as it soon extinguished a taper without becoming red, or being itself inflamed, barytes water was let up to the three cubical inches received over mercury, when a carbonate of barytes was immediately precipitated.

"The residue of several explosions, after the carbonic acid had been separated, was found, by the test of nitrous gas, to contain nitrogen or azotic gas; which does not proceed from any decomposition of atmospheric air, because the powder may

be made to explode under the exhausted receiver of an air-pump. It is therefore manifest that the gases generated during the combustion of the fulminating mercury, consist of carbonic acid and nitrogen gases.

XI. "The principal re-agents which decompose the mercurial powder are the nitric, the sulphuric, and the muriatic acids. The nitric changes the whole into nitrous gas, carbonic acid gas, acetic acid, and nitrate of mercury. I resolved it into these different principles, by distilling it pneumatically with nitric acid: this acid, upon the application of heat, soon dissolved the powder, and extricated a quantity of gas, which was found, by well-known tests, to be nitrous gas mixed with carbonic acid gas. The distillation was carried on until gas no longer came over. The liquor of the retort was then mixed with the liquor collected in the receiver, and the whole saturated with potash; which precipitated the mercury in a yellowish brown powder, nearly as it would have done from a solution of nitrate of mercury. This precipitate was separated by a filter, and the filtrated liquor evaporated to a dry salt, which was washed with alcohol. A portion of the salt being refused by this menstruum, it was separated by filtration, and recognized, by all its properties, to be nitrate of potash. The alcoholic liquor was likewise evaporated to a dry salt, which, upon the effusion of a little concentrate sulphuric acid, emitted acetic acid, contaminated with a feeble smell of nitrous acid, owing to the solubility of a small portion of the nitre in the alcohol.

XII. "The sulphuric acid acts upon the powder in a remarkable manner, as already has been noticed. A very concentrate acid produces an explosion nearly at the instant of contact, on account, I presume, of the sudden and copious disengagement of caloric from a portion of powder which is decomposed by the acid. An acid somewhat less concentrate likewise extricates a considerable quantity of caloric, with a good deal of gas; but, as it effects a complete decomposition, it causes no explosion. An acid, diluted with an equal quantity of water, by the aid of a little heat, separates the gas so much less rapidly, that it may with safety be collected in a pneumatic apparatus. But, whatever be the density of the acid (provided no explosion be produced), there remains in sulphuric liquor, after the separation of the gas, a white inflammable and uncrystallized powder mixed with some minute globules of quicksilver.

"To estimate the quantity, and observe the nature, of this inflammable substance, I treated 100 grains of the fulminating mercury with sulphuric acid a little diluted. The gas being separated, I decanted off the liquor as it became clear, and freed the insoluble powder from acid by elucoration with distilled water; after which, I dried it, and found it weighed only 84 grains; consequently had lost 16 grains of its original weight. Suspecting, from the operation of the nitric acid in the former experiment, that these 84 grains (with the exception of the quicksilver globules) were oxalate of mercury, I digested them in nitrate of lime, and found my suspicion just. The mercury of the oxalate united to the nitric acid, and the oxalic acid to the lime. A new insoluble compound was formed; it weighed, when washed and dry, 48.5 grains. Carbonate of potash separated the lime, and formed oxalate of potash, capable of precipitating lime-water, and muriate of lime: although it had been depurated from excess of alkali, and from carbonate acid, by a previous addition of acetic acid. That the mercury of the oxalate in the 84 grains had united to the nitric acid of the nitrate of lime was proved, by dropping muriatic acid into liquor from which the substance demonstrated to be oxalate of lime had been separated; for a copious precipitation of calomel instantly ensued.

"The fulphuric liquor, decanted from the oxalate of mercury, was now added to that with which it was elucorated, and the whole saturated with carbonate of potash. As effervescence ceased, a cloudiness and precipitation followed; and the precipitate, being collected, washed, and dried, weighed 3.4 grains: it appeared to be a carbonate of mercury. Upon evaporating a portion of the saturated fulphuric liquor, I found nothing but sulphate of potash; nor had it any metallic taste. There then remains, without allowing for the weight of the carbonic acid united to the 3.4 grains, a deficit from the 100 grains of mercurial powder of 12.6 grains, which I ascribe to the gas separated by the action of the sulphuric acid. To ascertain the quantity, and examine the nature, of the gas so separated, I introduced into a very small tubulated retort 50 grains of the mercurial powder, and poured upon it 3 drachms, by measure, of sulphuric acid, with the assistance of a gentle heat. I first received it over quicksilver; the surface of which, during the operation, partially covered itself with a little black powder.

"The gas, by different trials, amounted from 28 to 31 cubical inches: it at first appeared to be nothing but carbonic acid, as it precipitated barytes water, and extinguished a taper, without being itself inflamed, or becoming red. But, upon letting up to it liquid caustic ammoniac, there was a residue from 5 to 7 inches of a peculiar inflammable gas, which burnt with a greenish blue flame. When I made use of the water-tub, I obtained, from the same materials, from 25 to 27 inches only of gas, although the average quantity of the peculiar inflammable gas was likewise from 5 to 7 inches; therefore, the difference of the aggregate product, over the two fluids, must have arisen from the absorption, by the water, of a part of the carbonic acid in its nascent state. The variation of the quantity of the inflammable gas, when powder from the same parcel is used, seems to depend upon the acid being a little more or less dilute.

"With respect to the nature of the peculiar inflammable gas, it is plain to me, from the reasons I shall immediately adduce, that it is no other than the gas (in a pure state) into which the nitrous etherized gas can be resolved, by treatment with dilute sulphuric acid.

"The Dutch chemists have shewn, that the nitrous etherized gas can be resolved into nitrous gas, by exposure to concentrate sulphuric acid, and that, by using a dilute instead of a concentrate acid, a gas is obtained which enlarges the flame of a burning taper, so much like the gaseous oxyd of azote, that they mistook it for that substance, until they discovered that it was permanent over water, refused to detonate with hydrogen, and that the fallacious appearance was owing to a mixture of nitrous gas with inflammable gas.

"The inflammable gas separated from the powder answers to the description of the gas which at first deceived the Dutch chemists; 1st, in being permanent over water; 2dly, refusing to detonate with hydrogen; and, 3dly, having the appearance of the gaseous oxyd of azote, when mixed with nitrous gas.

"The gas separable by the same acid, from nitrous etherized gas, and from the mercurial powder, have therefore the same properties. Every chemist would thence conclude, that the nitrous etherized gas is a constituent part of the powder, and the inflammable and nitrous gas, instead of the inflammable and carbonic acid gas, been the mixed product extricated from it by dilute sulphuric acid.

"It however appears to me, that nitrous gas was really produced by the action of the dilute sulphuric acid; and that, when produced, it united to an excess of oxygen present in the oxalate of mercury.

"To explain how this change might happen, I must premise, that my experiments have shewn me that oxalate of mer-

cury can exist in two, if not in three states. 1st. By the discovery of Mr. Amélon, already quoted, the precipitate obtained by oxalic acid, from nitrate of mercury, fuses with a hissing noise. This precipitate is an oxalate of mercury, seemingly with excess of oxygen. Mercury dissolved in sulphuric acid and precipitated by oxalic acid, and also the pure oxyd of mercury digested with oxalic acid, give oxalates in the same state. 2dly. Acetate of mercury, precipitated by oxalic acid, although a true oxalate is formed, has no kind of inflammability. I consider it as an oxalate with less oxygen than those above mentioned. 3dly. A solution of nitrate of mercury, boiled with dulcified spirit of nitre, gives an oxalate more inflammable than any other; perhaps it contains moist oxygen.

"The oxalate of mercury remaining from the powder in the sulphuric liquor is not only always in the same state as that precipitated from acetate of mercury, entirely devoid of inflammability, but contains globules of quicksilver, consequently it must have parted with even more than its excess of oxygen; and, if nitrous gas was present, it would of course seize at least a portion of that oxygen. It is true, that globules of quicksilver may seem incompatible with nitrous acid; but the quantity of the one may not correspond with that of the other, or the dilution of the acid may destroy its action.

"As to the presence of the carbonic acid, it must have arisen either from a complete* decomposition of a part of the oxalate; or, admitting the nitrous etherized gas to be a constituent principle of the powder, from a portion of the oxygen, not taken up by the nitrous gas, being united with the carbon of the etherized gas.

XIII. "The muriatic acid, digested with the mercurial powder, dissolves a portion of it, without extricating any notable quantity of gas. The dissolution evaporated to a dry salt tastes like the corrosive sublimate; and the portion, which the acid does not take up, is left in a state of an uninflamable oxalate.

XIV. "These effects all tend to establish the existence of the nitrous etherized gas, as a constituent part of the powder; and likewise corroborate the explanation I have ventured to give of the action of the sulphuric acid. Moreover, a measured ounce and a half of nitrous acid, holding 100 grains of mercury in solution and 2 measured ounces of alcohol, yield 90 cubical inches only of gas: whereas, without the intervention of mercury, they yield 210 inches. Upon the whole, I trust it will be thought reasonable to conclude, that the mercurial powder is composed of the nitrous etherized gas, and of oxalate of mercury with excess of oxygen. 1st. Because the nitric acid converts the mercurial powder entirely into nitrous gas, carbonic acid gas, acetic acid, and nitrate of mercury. 2dly. Because the dilute sulphuric acid resolves it into an uninflamable oxalate of mercury, and separates from it a gas resembling that into which the same acid resolves the nitrous etherized gas. 3dly. Because an uninflamable oxalate is likewise left, after the muriatic acid has converted a part of it into sublimate. 4thly. Because it cannot be formed by boiling nitrate of mercury in dulcified spirit of nitre; although a very inflammable oxalate is by this means produced. 5thly. Because the difference of the product of gas, from the same measures of alcohol and nitrous acid, with and without

mercury in solution, is not trifling; and, 6thly. Because nitrogen gas was generated during its combustion in the glass globe.

"Should my conclusions be thought warranted by the reasons I have adduced, the theory of the combustion of the mercurial powder will be obvious to every chemist. The hydrogen of the oxalic acid, and of the etherized gas, is first united to the oxygen of the oxalate, forming water†; the carbon is saturated with oxygen, forming carbonic acid gas; and a part, if not the whole of the nitrogen of the etherized gas, is separated in the state of nitrogen gas; both which last gases, it may be recollected, were after the explosion present in the glass globe. The mercury is revived, and, I presume, thrown into vapour; as may well be imagined, from the immense quantity of caloric extricated, by adding concentrate sulphuric acid to the mercurial powder.

"I will not venture to state, with accuracy, in what proportions its constituent principles are combined. The affinities I have brought into play are complicated, and the constitution of the substances I have to deal with not fully known. But, to make round numbers, I will resume the statement, that 100 grains of the mercurial powder lost 16 grains of its original weight, by treatment with dilute sulphuric acid: 84 grains of the mercurial oxalate, mixed with a few minute globules of quicksilver, remained undissolved in the acid. The sulphuric liquor was saturated with carbonic of potash, and yielded 3.4 grains of carbonate of mercury. If 1.4 grain should be thought a proper allowance for the weight of carbonic acid in the 3.4 grains, I will make that deduction, and add the remaining 2 grains to the 84 grains of mercurial oxalate and quicksilver; I shall then have,

Of oxalate and mercury,	86 grains
And a deficit, to be ascribed to the nitrous etherized gas and excess of oxygen,	1.4
	100

"It may perhaps be proper to proceed still further, and recur to the 48.5 grains, separated by nitrate of lime from the 84 grains of mercurial oxalate and globules of quicksilver, in the 11th section. These 48.5 grains were proved to be chiefly oxalate of lime; but they likewise contained a minute inseparable quantity of mercury, almost in the state of quicksilver, formerly part of the 84 grains from which they were separated. Had the 48.5 grains been pure calcareous oxalate, the quantity of pure oxalic acid in them would, according to Bergmann, be 23.28 grains. Hence, by omitting the 2 grains of mercury, in the 3.4 grains of carbonate, 100 grains of the mercurial powder might have been said to contain of pure oxalic acid 23.28 grains; of mercury 62.72 grains; and of nitrous etherized gas and excess of oxygen 1.4 grains. But, as the 48.5 grains were not pure oxalate, inasmuch as they contained the mercury they received from the 84 grains, from which they were generated by the nitrate of lime, some allowance must be made for the mercury successively intermixed with the 84 grains and the 48.5 grains. In order to make corresponding numbers, and allow for unavoidable errors, I shall estimate the quantity of that mercury to have amounted to 2 grains, which I must of course deduct from the 33.28

* Inflammable oxalate of mercury, made to fuse in a retort connected with the quicksilver tube, gives out carbonic acid gas.

† Drops of water were observed on the internal surface of the globe, the day after several explosions had been produced in its centre.

grains of oxalic acid. I shall then have the following statement:

That 100 grains of fulminating mercury ought to contain of pure, oxalic acid,	21,28 grains.
Of mercury formerly united to the oxalic acid,	60,72
Of mercury dissolved in the sulphuric liquor,	2
And of mercury left in the sulphuric liquor after the separation of the gases,	2
Total of mercury,	64,72
Of nitrous etherized gas, and excess of oxygen,	14
	100

"Since 100 grains of the powder seem to contain 64,72 grains of mercury, it will be immediately enquired, what becomes of 100 grains of quicksilver, when treated as directed, in the description of the process for preparing the fulminating mercury.

"It has been stated (in section IX.) that 100 grains of quicksilver produce, under different circumstances, from 120 to 132 grains of mercurial powder; and, if 100 grains of this powder contain 64,72 grains, 120 grains, or 132 grains, must, by parity of reasoning, contain 78,06 grains, or 85,47 grains; therefore 13,34 grains, or 20,75 grains, more of the 100 grains are immediately accounted for; because 64,72 grains + 13,34 grains = 78,06, and 64,72 grains + 20,75 grains = 85,47 grains. The remaining deficiency of 21,94 grains, or 14,53 grains, which, with the 78,06 grains, or 85,47 grains, would complete the original 100 of quicksilver, remains partly in the liquor from which the powder is separated, and is partly volatilized in the white dense fumes, which in the beginning of this paper I compared to the liquor fumans of Libavius. The mercury cannot, in either instance, be obtained in a form immediately indicative of its quantity; and a series of experiments, to ascertain the quantities in which many different substances can combine with mercury, is not my present object. After observing, that the mercury left in the residuary liquor can be precipitated in a very subtle dark powder, by carbonate of pot-ash, I shall content myself with examining the nature of the white fumes.

XV. "It is clear, that these white fumes contain mercury: they may be wholly condensed in a range of Woulfe's apparatus, charged with a solution of muriate of ammoniac. When the operation is over, a white powder is seen floating with ether on the saline liquor, which, if the bottles are agitated, is entirely dissolved. After the mixture has been boiled, or for some time exposed to the atmosphere, it yields to caustic ammoniac a precipitate, in all respects similar to that which is separated by caustic ammoniac from corrosive sublimate.

"I would infer from these facts, that the white dense fumes consist of mercury, or perhaps oxyd of mercury, united to the nitrous etherized gas; and that, when the muriate of ammoniac containing them is exposed to the atmosphere, or is boiled, the gas separates from the mercury; and the excess of nitrous acid, which always comes over with nitrous ether, decomposes the ammoniacal muriate of sublimate, and forms corrosive mercurial muriate or sublimate. This theory is corroborated by comparing the quantity of gas estimated to

be contained in the fulminating mercury with the quantities of gas yielded from alcohol and nitrous acid, with and without mercury in solution; not to mention that more ether, as well as more gas, is produced without the intervention of mercury; and that, according to the Dutch chemists, the product of ether is always in the inverse ratio to the product of nitrous etherized gas. Should a further proof be thought necessary of the existence of the nitrous etherized gas in the fulminating mercury, as well as in the white dense fumes, it may be added, that, if a mixture of alcohol and nitrous acid holding mercury in solution be so dilute, and exposed to a temperature so low, that neither ether nor nitrous etherized gas are produced, the fulminating mercury, or the white fumes, will never be generated; for, under such circumstances, the mercury is precipitated chiefly in the state of an inflammable oxalate. Further, when we consider the different substances formed by an union of nitrous acid and alcohol, we are so far acquainted with all, except the ether and the nitrous etherized gas, as to create a presumption, that no others are capable of volatilizing mercury, at the very low temperature in which the white fumes exist, since, during some minutes, they are permanent over water of 40° Fahrenheit.

XVI. "Hitherto, as much only has been said of the gas which is separated from the mercurial powder by dilute sulphuric acid, as was necessary to identify it with that into which the same acid can resolve the nitrous etherized gas: I have further to speak of its peculiarity*.

"The characteristic properties of the inflammable gas seem to me to be the following: 1st. It does not diminish in volume, either with oxygen or nitrous gas. 2dly. It will not explode with oxygen by the electric shock, in a close vessel, 3dly. It burns like hydrocarbonate, but with a blueish-green flame; and, 4thly. It is permanent over water (section xii).

"It is of course either not formed, or is convertible into nitrous gas by the concentrate nitric and muriatic acids; because by those acids, no inflammable gas was extricated from the powder.

"Should this inflammable gas prove not to be hydrocarbonate, I shall be disposed to conclude, that it has nitrogen for its basis; indeed, I am at this moment inclined to that opinion, because I find that Dr. Priestley, during his experiments on his dephlogistated nitrous air, once produced a gas which seems to have resembled this inflammable gas, both in the mode of burning and in the colour of the flame.

"After the termination of the common solution of iron in spirit of nitre, he used heat, and got, says he, 'such a kind of air as I had brought nitrous air to be, by exposing it to iron, or liver of sulphur; for, on the first trial, a candle burned in it with a much enlarged flame. At another time, the application of a candle to air produced in this manner was attended with a real, though not a loud explosion; and, immediately after this, a greenish-coloured flame descended from the top to the bottom of the vessel in which the air was contained. In the next produce of air, from the same process, the flame descended blue, and very rapid, from the top to the bottom of the vessel.'

"These greenish and blue coloured flames, descending from the top to the bottom of the vessel, are precisely descriptive of the inflammable gas separated from the powder. If it can be produced with certainty by the repetition of Dr. Priestley's experiments, or should it by any means be got pure from the

* It must be first noticed, that it is never pure when obtained from the nitrous etherized gas; nor am I aware how it is to be purified, unless the nitrous gas could be taken from it, without being converted into nitrous acid; for, by that acid, it would probably be itself converted into nitrous gas.

nitrous etherized gas, my curiosity will excite me to make it the object of future research; otherwise, I must confess, I shall feel more disposed to prosecute other chemical subjects: for having reason to think that the density of the acid made a variation in the product of this gas, and having never found that any acid, however dense, produced an immediate explosion, I once poured 6 drachms of concentrate acid upon 50 grains of the powder. An explosion, nearly at the instant of contact, was effected: I was wounded severely, and most of my apparatus destroyed. A quantity moreover of the gas I had previously prepared, was lost by the inadvertency of a person who went into my laboratory, whilst I was confined by the consequences of this discouraging accident. But, should any one be desirous of giving the gas a further examination, I again repeat, that, as far as I am enabled to judge, it may with safety be prepared by pouring 3 drachms of sulphuric acid, diluted with the same quantity of water, upon 50 grains of the powder, and then applying the flame of a candle until gas begins to be extricated. The only attempt I have made to decompose it, was by exposing it to copper and ammoniac; which during several weeks did not effect the least alteration.

"I will now conclude (says Mr. Howard), by observing, that the fulminating mercury seems to be characterized by the following properties:

"It takes fire at the temperature of 368 Fahrenheit; explodes by friction*, by flint and steel, and by being thrown into concentrate sulphuric acid. It is equally inflammable under the exhausted receiver of an air-pump, as surrounded by atmospheric air; and it detonates loudly, both by the blow of a hammer, and by a strong electrical shock.

"Notwithstanding the composition of fulminating silver and of fulminating gold, differ essentially from that of fulminating mercury, all three have similar qualities. In tremendous effects, silver undoubtedly stands first, and gold perhaps the last. The effects of the mercurial powder and of gunpowder admit of little comparison. The one exerts, within certain limits, an almost inconceivable force: its agents seem to be gas and caloric, very suddenly set at liberty, and both mercury and water thrown into vapour. The other displays a more extended but inferior power: gas and caloric are, comparatively speaking, liberated by degrees; and water, according to Count Rumford, is thrown into vapour†.

"Hence it seems that the fulminating mercury, from the limitation of its sphere of action, can seldom, if ever, be applied to mining; and, from the immensity of its initial force, cannot be used in fire-arms, unless in cases where it becomes an object to destroy them; perhaps, where it is the practice to spike cannon, it may be of service, because I apprehend it may be used in such a manner as to burst cannon, without dispersing any splinters.

"The inflammation of fulminating mercury by concussion offers nothing more novel or remarkable, than the inflammation, by concussion, of many other substances. The theory of such inflammations has been long since exposed by the celebrated Mr. Berthollet, and confirmed by Messieurs Fourcroy, and Vauquelin: yet, I must confess, I am at a loss to understand why a small quantity of mercurial powder made to detonate by the hammer, or the electric shock, should produce a report so much louder than when it is inflamed by a

match, or by flint and steel. It might at first be imagined, that the loudness of the report could be accounted for, by supposing the instant of the inflammation, and that of the powder's confinement between the hammer and anvil, to be precisely the same; but, when the electrical shock is sent through or over a few grains of the powder, merely laid on ivory, and a loud report is the consequence, I can form no idea of what causes such a report.

"The operation by which the powder is prepared, is perhaps one of the most beautiful and surprising in chemistry; and it is not a little interesting to consider the affinities which are brought into play. The superabundant nitrous acid of the mercurial solution must first act on the alcohol, and generate ether, nitrous etherized gas, and oxalic acid. The mercury unites to the two last in their nascent state, and relinquishes fresh nitrous acid, to act upon any unaltered alcohol. The oxalic acid, although a predisposing affinity seems exerted in favour of its quantity, is evidently not formed fast enough to retain all the mercury; otherwise, no white fumes, during a considerable period of the operation, but fulminating mercury alone, would be produced.

"Should any doubt still be entertained of the existence of the affinities which have been called predisposing or conspiring, a proof that such affinities really exist, will, I think, be afforded, by comparing the quantity of oxalic acid which can be generated from given measures of nitrous acid and alcohol, with the intervention of mercury, and the intervention of other metals. For instance, when two measured ounces of alcohol are treated with a solution of 100 grains of nickel in a measured ounce and a half of nitrous acid, little or no precipitate is produced; yet, by the addition of oxalic acid to the residuary liquor, a quantity of oxalate of nickel, after some repose, is deposited. Copper affords another illustration; 100 grains of copper dissolved in a measured ounce and a half of nitrous acid, and treated with alcohol, yielded me about 18 grains only of oxalate; although cupreous oxalate was plentifully generated, by dropping oxalic acid into the residuary liquor. About 21 grains of pure oxalic acid seem to be produced, from the same materials, when 100 grains of mercury are interposed. (See section XIV.) Besides, according to the Dutch paper, more than once referred to, acetic acid is the principal residue after the preparation of nitrous ether. How can we explain the formation of a greater quantity of oxalic acid, from the same materials, with the intervention of 100 grains of mercury, than with the intervention of 100 grains of copper, otherwise than by the notion of conspiring affinities, so analogous to what we see in other phenomena of nature?

"I have attempted, without success, to communicate fulminating properties, by means of alcohol, to gold, platinum, antimony, tin, copper, iron, lead, zinc, nickel, bismuth, cobalt, arsenic, and manganese; but I have not yet sufficiently varied my experiments, to enable me to speak with absolute certainty. Silver, when 20 grains of it were treated with nearly the same proportions of nitrous acid and alcohol as 100 grains of mercury, yielded, at the end of the operation, about 3 grains of a grey precipitate, which fulminated with extreme violence. Mr. Cruickshank had the goodness to repeat the experiment: he dissolved 40 grains of silver in 2 ounces of the strongest nitrous acid diluted with an equal

* Consequently it should not be inclosed in a bottle with a glass stopper.

† See Philosophical Transactions for the year 1797, p. 222. The hard black substance mentioned by the Count, as remaining after the combustion of gunpowder, must, I believe, have carbonate of pot-ash. The conjecture, that it is white when globe evinced.

quantity of water, and obtained (by means of 2 ounces of alcohol) 60 grains of a very white powder, which fulminated like the grey precipitate above described. It probably combines with the same principles as the mercury, and of course differs from Mr. Berthollet's fulminating silver, before alluded to. I observe, that a white precipitate is always produced in the first instance; and that it may be preserved by adding water, as soon as it is formed; otherwise, when the mother liquor is abundant, it often becomes grey, and is redissolved."

Several trials of the mercurial powder were afterwards made at Woolwich, in conjunction with Colonel Blomfield and Mr. Cruickshank, upon heavy guns, carronades, &c. from which Mr. Howard generally infers, that any piece of ordnance might be destroyed, by employing a quantity of the mercurial powder equal in weight to one half of the service-charge of gunpowder; and, from the seventh and last experiment, we may also conclude, that it would be possible for to proportion the charge of mercurial powder to the size of different cannons, as to burst them without dispersing any splinters. But the great danger attending the use of fulminating mercury, on account of the facility with which it explodes, will probably prevent its being employed for that purpose.

"In addition to the other singular properties of the fulminating mercury (says Mr. Howard), it may be observed, that two ounces inflamed in the open air, seem to produce a report much louder than when the same quantity is exploded in a gun capable of resisting its action. Mr. Cruickshank, who made some of the powder, by my process, remarked that it would not inflame gunpowder. In consequence of which, we spread a mixture of coarse and fine-grained gunpowder upon a parcel of the mercurial powder; and, after the inflammation of the latter, we collected most, if not all, of the grains of gunpowder. Can this extraordinary fact be explained by the rapidity of the combustion of fulminating mercury? or is it to be supposed (as gunpowder will not explode at the temperature at which mercury is thrown into vapour) that sufficient caloric is not extricated during this combustion? From the late opportunity I have had of conversing with Mr. Cruickshank, I find that he has made many accurate experiments on gunpowder; and he has permitted me to state, that the matter which remains after the explosion of gunpowder consists of pot-ash united with a small proportion of carbonic acid, sulphate of pot-ash, a very small quantity of sulphuret of pot-ash, and unconsumed charcoal. That 100 grains of good gunpowder yielded about 53 grains of this residuum, of which three are charcoal. That it is extremely deliquescent, and, when exposed to the air, soon absorbs moisture sufficient to dissolve a part of the alkali; in consequence of which, the charcoal becomes exposed, and the whole assumes a black or very dark colour. Mr. Cruickshank likewise informs me, that after the combustion of good gunpowder under mercury, no water is ever perceptible."

FUMIGATION (*Encycl.*) This mode of affecting the human constitution with mercury, was much practised by the celebrated Astruc, and has since been revived in France, by Lalouette. Mr. Abernethy, who, in his *Surgical Cases*, p. 194, gives the following account of the use of mercurial fumigations, professes his approbation of that practice. He presents his readers with some cases which clearly shew the advantages that attend this method of treating lues venerea. The grounds of preference in favour of fumigation, are: *First*, from its affecting the constitution when other means have failed; and, *secondly*, from its producing its effects in a much shorter time than any other mode requires.

"I beg leave, however, previously to observe (says Mr.

Abernethy), that the term, mercurial fumigations, is apt to excite wrong ideas of this method in the minds of surgeons. Fumigations have been, of late, generally employed to correct local diseases; and they have often, by design, been made of an acrid quality. And even when they were formerly employed with a view of affecting the constitution, it was at a time when the chemical compounds of quicksilver were not understood, and sufficient attention was not paid to those circumstances on which the success of their application depends.

"But, in the year 1776, the Chevalier Lalouette, a physician at Paris, laid before the public an account of a new mode of mercurial fumigation, free from the inconveniences of former ones, and which, in the space of thirty-five years, he had successfully employed in more than four hundred cases, that had resisted all the ordinary methods of cure. His method consisted in enclosing the patient, previously undressed, in a kind of box resembling a sedan chair, with an opening at the top to let out the head, and another at the bottom, to which was fitted a small grate or furnace, having in it a heated iron for converting the mercurial retort into fume. The preparation he made use of was a kind of calomel, which, by repeated sublimation from iron-sfilings, was so far deprived of its muriatic acid, as to be in part reduced into running quicksilver; and, while it possessed considerable volatility, was perfectly irritating. Some of this powder being strewn upon the hot iron placed below, was immediately converted into smoke, which surrounded the patient's body, and after some time settled on his skin in the form of a white and very fine calx of quicksilver: a complete dress, having its inner surface fumigated with the same powder, was then put on.—The remedy being thus generally applied to the mouths of the cutaneous absorbents, soon got admission into the circulating fluids; and the constitution became thereby more speedily affected than by any other process known before."

For a more particular account of the chemical preparations used by M. Lalouette, and his manner of employing them, Mr. Abernethy refers to his treatise, which was published in 1776. He adds, "With regard to the process, I would only further observe, that the feelings of the patient during it, are not at all unpleasant, provided the heat be properly regulated; that there is nothing uncleanly or disagreeable in the powder applied to the skin; and that all who have had an opportunity of comparing it with the common method by innunction, have been highly pleased with the superior advantages attending it."

The fumigating powder of M. Lalouette being a very operose and expensive preparation, and having no advantage over one made by abstracting the muriatic acid from calomel, Mr. Abernethy employed the following in lieu of it: Two drachms of aqua ammoniac were added to six ounces of distilled water, and four ounces of calomel thrown into this liquor, and shaken up with it; the powder was afterwards separated by a filter, and dried.

"The powder thus obtained (says the author), is of a grey colour, and contains a good deal of quicksilver in its metallic state, which of course is extremely volatile, but becomes oxydated when raised into fume, and afterwards condenses into a white and very fine dust.

"This mode of using mercury is not, however, so well adapted to hospital practice; for sometimes the iron was too much heated, and the patients were made by this means to perspire profusely, so that the powder was formed into a paste, which was irregularly incrustated on the skin; besides, the patients either could not or would not wear a complete under-dress; and in that case the powder was wiped away, and the plan of treatment frustrated: for the design is to allow of a

constant absorption of this subtle preparation of quicksilver from the whole surface of the body."

Mr. Abernethy gives some cases in which this remedy was very speedy in its effects; and could relate (he asserts) many others in which fumigation accomplished with *facility* the cure of complaints which had resisted long-continued mercurial courses both by friction and internal exhibition. "It is reasonable to think (continues he), that this object will be more certainly obtained by the absorption thus taking place from almost the whole surface of the body, than by any other method hitherto devised. Yet it is but right to say, that my hopes of success from it have not always been fulfilled; and that, in some few cases where mercury shewed a particular tendency to act on the bowels without affecting the mouth, the mercurial fumes seemed to produce this effect even sooner than the ointment had done: and in one young man, whose mouth neither frictions nor the internal use of mercury could be made to affect, but in whom they occasioned constant tremors of the muscles, and spasms of the bowels, the fumigations were not attended with any better success. Happily, however, such cases are rare; and in general the fumigations affect the constitution speedily, and in the usual manner."

To the objections which have been brought against the cure by fumigations, Mr. Abernethy makes this reply. He says, "I have heard it objected, that fumigation cannot be depended on for the cure of lues. But I never knew it fail, nor do I see why mercury, used thus, should, when absorbed, prove less effectual than when this mineral is combined with lard in the common ointment. If fumigations in this mode have failed, it was more probably owing to their being improperly managed, than to any insufficiency peculiar to them. Thus, if administered frequently and largely at first, they may have considerably affected the mouth without proportionally affecting the constitution in general; or, from the quickness with which they heal venereal ulceration, the cure may have been too soon supposed complete, and their use discontinued before they had entirely eradicated the disease. Under proper management, I have no doubt but mercury, employed in this manner, will be found adequate to the cure of every variety of the disease."

"Besides their general application, there is another way in which mercurial fumigations may be occasionally employed with advantage, though the benefit is less important; and perhaps this method may be regarded merely as a refinement in the practice of surgery. In local disease of the joints, such, for instance, as frequently takes place in the knee, and in farcomatous enlargements of the breast in women, Mr. Sharp and Mr. Blinck have long accustomed to direct fumigated stockings, or under-waistcoats, to be worn; when the complaints have been relieved, and the constitutions of the patients affected, without the trouble and unpleasantness arising from the use of the common mercurial ointment."

FUNGIBLES, in Scots law, are such things as are estimated by their number, weight, or measure; as coin, butter, ale, &c.

FUORLI, a town of Naples, in Abruzzo Citeriore, 21 miles S.E. of Solmona.

FURNES, a town of Flanders, seated near the German Ocean, on the canal from Bruges to Dunkirk. It was one of the barrier towns; but, in 1781, the emperor Joseph II. expelled the Dutch garrison. It was taken by the French in 1793, and is 12 miles E. of Dunkirk. Long. 2. 45. E. Lat. 51. 4. N.

FURRUCKABAD, a district of Hindoostan Proper, contiguous to the W. bank of the Ganges, and surrounded by

Oude. It is little more than 30 miles in extent, and belongs to a chief of the Patan Rohilla tribe. The principal town is of the same name, 70 miles E. of Agra, and 76 N. W. of Lucknow. Long. 79. 30. W. Lat. 27. 28. N.

FURSTENBURG, a principality of Suabia, bounded by the duchy of Wirtemberg, the county of Hohenburg and other territories of the house of Austria, by the Brisgaw, the Black Forest, and the lake and bishopric of Constance. In this state the river Danube takes its rise.

FURSTENFELD, a town of Lower Stiria, with a castle, on the river Aufnitz, 50 miles S. of Vienna. Long. 16. 5. E. Lat. 47. 23. N.

FURSTENWALD, a town of Germany, in the Middle-Marche of Brandenburg, seated on the Spree, 20 miles W. of Francfort on the Oder. It was taken by the Swedes in 1631. Long. 14. 8. E. Lat. 52. 23. N.

FURSTENWERDER, a town of Upper Saxony, in the Ucker Marche of Brandenburg, 10 miles W.N.W. of Prenzlau.

FURT, a town of Lower Bavaria, situate on the Champe, 56 miles N.N.W. of Passau, and 86 N.N.E. of Munich. Long. 12. 46. E. Lat. 49. 13. N.

FURTH, a town of Franconia, in the principality of Anspach, on the Rednitz, four miles W. of Nuremberg.

FUTTYPOUR, SICRI, a considerable town of Hindoostan Proper, in the province of Agra. It is seated under a range of hills, the southern boundary of an immense plain, in which, for the greatest part, not a shrub is to be seen, and the soil is almost as fine as hair powder; a circumstance productive of the most disagreeable effects, when this fine dust is taken up by the hot winds from the westward. Its situation, too, is unhealthy, from the indifferent water with which the whole country abounds; but the country immediately near the town, is in tolerable cultivation. On the summit of the highest hill is a large mosque, built by the emperor Acbar, in the first style of Moorish architecture; and at the foot of this hill are the ruins of an imperial palace, which occupy a great extent of ground. It is 42 miles W. of Agra. Long. 77. 45. E. Lat. 27. 0. N.

FYAL, one of the Azores, or Western Islands. It is well cultivated; and has abundance of chestnuts, beeches, myrtles, and aspen-trees. The cottages of the common people are built of clay, thatched with straw; and are small, but cleanly and cool. The most considerable place is called Villa de Horta. Long. 28. 36. W. Lat. 38. 32. N.

FYERS, a river in Invernesshire, which, descending from the S. flows toward Loch Ness. Over this river is built a stupendous bridge, on two opposite rocks; the top of the arch being above 100 feet from the level of the water. A little below the bridge is the celebrated Fall of Fyers, where a great body of water darts through a narrow gap between two rocks, then falls over a vast precipice into the bottom of a chafin.

FYNE, Loch, an inlet of the Atlantic, in Argyleshire, nearly 40 miles in length. It receives and returns a tide on each side of the Isle of Arran, which is directly opposite its entrance. It is indented with bays; and at certain seasons, its waters are filled with herrings, when it becomes the resort of numerous fishing vessels.

FYZABAD, a city of Hindoostan Proper, in the territory of Oude, of which it was once the capital. Here are the remains of a vast building, the palace of the late nabob Sujah-ul Dowlah. The city is very populous; but since the removal of the court of Oude to Lucknow, the people are of the lowest class. It is seated on the Gogra, 80 miles E. of Lucknow, and 500 N.W. of Calcutta. Long. 82. 30. E. Lat. 26. 34. N.

G.

GABARET, a town of France, in the department of Gers, seated on the Gers, 20 miles W. of Condom. Lon. o. 6. E. Lat. 44. 59. N.

GABEI, a town of Bohemia, where Prince Henry of Prussia entered that country, after having gained an advantage over the Austrians, in 1778. It is 45 miles N. of Prague.

GABIAN, a village of France, in the department of Herault, famous for its mineral waters, nine miles N.W. of Beziers.

GABIN, a town of Poland, in the palatinate of Rava, 50 miles N.W. of Warfaw. Long. 19. 45. E. Lat. 52. 26. N.

GADEBUSCH, a town of Lower Saxony, in the duchy of Mecklenburg, near which the Swedes defeated the Danes in 1712. It is 16 miles N.N.W. of Schwerin.

GAETA, an ancient town of Naples, in Terra di Lavoro, with a fort, a citadel, a harbour, and a bishop's see. It was taken by the Austrians in 1707, and by the Spaniards in 1714. It is seated at the foot of a mountain, near the sea, 30 miles N.W. of Capua. Long. 13. 47. E. Lat. 51. 30. N.

GAIRLOCH, a large bay of Scotland, on the W. coast of Ross-shire, which gives name to a tract of land near it. The fishing of cod, and other white fish, is here very considerable.

GALACZ, or **GALASI**, a town of Bulgaria, seated near the Danube, between the mouths of the Pruth and Seret, 55 miles W. of Imael, and 120 S.S.W. of Bender. Long. 28. 24. E. Lat. 45. 24. N.

GALASHIELS, a village in Selkirkshire, near the confluence of the Gala and Tweed. Here is a flourishing manufacture of woollen cloth, called Galashielsgray, being of a dark colour and coarse texture; flannels and superior cloths are also made here. It is 25 miles S. by E. of Edinburgh.

GALASO, a river of Naples, in Oranto, which rises in the opening near Oria, and falls into the gulf of Taranto.

GALFALLY, a town of Ireland, in the county of Tipperary, 23 miles S.E. of Limerick. Long. 8. 20. W. Lat. 52. 15. N.

GALISTIO, a town of Spain, in Estremadura, 10 miles N.W. of Placentia. Long. 5. 8. E. Lat. 40. 2. N.

GALITSCH, a town of Russia, in the government of Koftroma, on the S. side of a lake to which it gives name, 56 miles E.N.E. of Koftroma. Long. 22. 54. E. Lat. 57. 56. N.

GALLAM, the capital of a kingdom of the same name, in Africa, on the river Senegal. Long. 9. 55. W. Lat. 14. 25. N.

GALLARDON, a town of France, in the department of Eure and Loire, 12 miles N.E. of Chartres.

GALIPOLI, a strait between European and Asiatic Turkey. It forms the communication between the Archipelago and the sea of Marmora, and is defended at the S.W. entrance by the Dardanelles. It is here two miles over, and is thirty-three miles long. It was anciently called the Hellespont. See DARDANELLES.

GALVANISM, an appellation given to the influence of metals, by mere external contact with the human body, discovered by Prof. GALVANI, at Bologna, about ten years since, and which he called *Animal Electricity*. The following account of this interesting discovery is given by Dr. Willich in THE DOMESTIC ENCYCLOPEDIA.

"Certain convulsive motions on the nerves of living and dead animals," says the doctor, "may be excited by the ap-

plication of metallic or other conductors of electricity; but these motions may also be induced, by simply touching the animal fibre with two different metals, that are brought in contact with each other at the same moment. This surprising phenomenon has lately been resorted to, in order to ascertain whether a drowned, suffocated, or otherwise suddenly deceased person, was really or apparently dead. For this purpose, Dr. CREVE, Prof. of Medicine in the University of Mayence, has contrived an instrument formed like a bow, both ends of which are furnished with two small round plates. The whole is composed of two parts made of different metals; one-half of solid zinc, the other of fine silver; or gold and zinc, or lead, tin, and gold. The proportion of the first metal should be less than the other combined with it; namely, the weight and size of the zinc-plate should be less than the opposite one of gold. Both plates are only screwed on the bow, which chiefly consists of silver. But, where this instrument cannot be procured on the spur of the occasion, a small piece of tin or lead, and a silver coin of a moderate size (for instance a shilling, or half-a-crown piece) may be substituted. Although any part of the body may be fixed upon for making the experiment with persons apparently dead, yet the upper arm will be the most proper. The skin, however, in that part where the incision is made, ought to be found, and not of a gangrenous appearance. The muscles must be cleared of all fat and cellular texture, as far as this be practicable; and the blood is to be taken up by a sponge dipped in water. Next, the muscle should be slightly extended, by stretching the arm; and, in order to keep the lips of the wound separate, the skin ought to be expanded, and the muscular fibres clearly exposed. After these preparatory steps, either the instrument above described, or two loose metallic plates, are to be applied towards the centre of the hollow place or wound made by the incision, and both flat plates brought into perfect contact with the bare muscular fibres. If any irritability exist, or remain, in the system of the subject, the muscular fibres will be contracted and twisted in a manner similar to spasms; or convulsive motions will be evident: every symptom, however, disappears on withdrawing the instrument, and again becomes manifest on re-applying it as before. But no motion whatever will be perceptible, if all irritability be lost or destroyed, in which case the body may be considered as *irrecoverably dead*.—In those instances, where persons have been deprived of life by intense cold, a moderate degree of warmth should be previously applied, with a view to render the limbs flexible. Hence, this experiment cannot with propriety be undertaken, till all other means of restoring animation have been *unsuccessfully* employed.

"Whatever two metals be chosen, they will, with few exceptions, produce those remarkable contractions, when applied in the manner before described; but the most powerful are, zinc and silver, or zinc and gold; or in general, zinc, tin, or lead, when used in combination with gold, silver, molybdena, steel, or copper.

"These singular phenomena take place in consequence of a mutual communication between any two points of contact, whether more or less distant, in a system of muscular and nervous organs. The extent of this communication may be considered as a complete circle divided into two parts, one of which comprising the organs of the animal under the experiment, is called the *animal arc*; the other, which is formed by

the metals or *galvanic* exciters, is denominated the *excitatory arc*; and consists of more than one piece, of various kinds.

Besides the effects thus produced on the muscles, the impressions made on the organs of the sense are equally remarkable. And as the experiments illustrating them may be easily repeated, we shall specify some of the most interesting. For instance, if a thin plate of zinc be placed on the upper surface of the tongue, and a half-crown, shilling, or silver tea-spoon, be laid on the lower surface of the tongue, and both metals after a short space of time be brought into contact, a peculiar sensation similar to taste, will be perceived at the moment when the mutual touch happens. If the silver be put beneath, and the zinc upon the tongue, the same sensation will arise, but in a weaker degree, resembling diluted ammoniac, from which it in all probability derives its origin.

If a silver probe be introduced as far as convenient into one of the nostrils, and then be brought into contact with a piece of zinc placed on the tongue, a sensation not unlike a strong flash of light will be produced in the corresponding eye, at the instant of contact. A similar perception will result, both at the moment of contact and at that of separation, if one of the metals be applied as high as possible between the gums and upper lip, and the other in a similar situation with the under lip, or even under the tongue.—Lastly, when a probe or rod of zinc, and another of silver, are introduced as far back as possible into the roof of the mouth, the irritations produced by bringing the external ends into contact, are very powerful; and that caused by the zinc is similar in taste to the sensation arising from its application to the tongue.

No method has hitherto been discovered, of applying the Galvanic influence in such a manner as to affect the senses of smell, hearing, and touch; though several eminent philosophers have carefully investigated the subject. Nor are the causes of these phenomena clearly ascertained; Galvani and some of his followers, supposing them to depend on the electric fluid, while others attribute them to the influence of various physical agency.

In this state was Galvanism, when in the year 1800, Signor Volta, professor of natural philosophy, at Como, in the Milanese, communicated to Sir Joseph Banks, a discovery of the vast accumulation of this power: it was accordingly presented to the Royal Society, from the 2d part of *whole Transactions*, for 1800, we have selected the following account:

Signor Volta's apparatus consists of a number of copper or silver plates (which last are preferable), together with an equal number of plates composed of tin, or still better of zinc, and a similar number of pieces of card, leather, or woollen cloth, the last of which substances appears to be the most suitable. These last should be well soaked in water saturated with common salt, muriat of ammonia, or, more effectually, with nitre.—The silver or copper may be pieces of money, and the plates of zinc may be cast of the same size. A pile is then to be formed, by placing a piece of silver on a corresponding one of zinc, and on them a piece of wet cloth or card: which is to be repeated alternately, till the number required be arranged in regular succession. But, as the pieces are apt to tumble down, if their numbers be considerable, unless properly secured, it will be advisable to support them by means of three rods of glass, or baked wood, fixed into a flat wooden pedestal, and touching the pieces of metal at three equidistant points. Upon these rods may be made to slide a small circular piece of wood, perforated with three holes, which will serve to keep the top of the pile firm, and the different layers in close contact. The moistened pieces should likewise be somewhat smaller than those of metal, and gently squeezed before they are applied, to prevent the superfluous moisture from insinuating itself between the pieces of metal.

Thus constructed, the apparatus will afford a perpetual current of the animal-electric fluid, or Galvanic influence, through any conductor that communicates between the uppermost and lowest plate; and, if one hand be applied to the latter, and the other to the highest metal, a shock will be perceived, which may be repeated as often as the contact is renewed. This shock greatly resembles that given by the torpedo, or *gymnotus electricus*: and, according to the larger size of the metallic plates, the shock will be proportionally stronger. The intensity of the charge, however, is so low, that it cannot penetrate the dry skin; it will therefore be necessary to wet both hands, and to grasp a piece of metal in each, in order to produce the desired effect: its power may be considerably increased, both by an elevation of temperature, and by augmenting the number of pieces that compose the pile. Thus 20 pieces of each will emit a shock, that is very perceptible in the arms; if 100 be employed, a very severe but tremulous and continued sensation will extend even to the shoulders; and, if the surface of the skin be broken, the action of the Galvanic influence will be uncommonly painful.

The sensation of a flash, or shock with this apparatus, does not materially differ from that produced by two simple plates; but it may be effected in various ways, especially if one or both hands be applied in a wet state to the lowest plate of the pile; or any part of the face be brought in contact with a wire communicating with the top piece. Further, if a wire be held between the teeth, so as to rest upon the tongue, that organ, as well as the lips, will become convulsed, the flash will appear before the eye, and a very pungent taste will be perceived in the mouth.

In an account of some experiments on Galvanic electricity, Mr. W. Cruickshank, of the Royal Artillery, Woolwich, communicates the following particulars:

"In subjecting a number of fluids to the action of Galvanism," says he, "several facts have been discovered, which to me, at least, are perfectly new, and which appear to throw some light on the nature and powers of this new influence.

"I shall, therefore, without any further apology, give a brief detail of some of the most important, hoping that they may prove acceptable to those who are employed in the same pursuits.

"I shall not give any particular account of the apparatus employed, being a pile, and not differing materially from that in use. I shall only just observe, that it consisted of plates of zinc and silver, of about 1.6 inches square, and that the number of each employed in the following experiments varied from 40 to 100, according to the power required.

"I found that a solution of the muriate of ammonia answered better for moistening the interposed papers than common water.

"When the machine was in full action, sparks, which were perfectly visible in the day-time, could be taken at pleasure, by making a communication in the usual way between the extremities of the pile, and a small report or snap could be heard; the shock given at that time was very strong, and a gold leaf electrometer, placed in the circle of communication was very sensibly affected: these circumstances, some of which I believe have been already ascertained by Messrs. Nicholson and Carlisle, shew the strong resemblance of this influence to electricity. These gentlemen have likewise discovered that Galvanism decomposes water with much greater facility than electricity, but with phenomena somewhat different."

The following is an account of some Galvanic combinations formed by the arrangement of single metallic plates and fluids, analogous to the new Galvanic apparatus of Mr. Volta, by Mr. Humphry Davy, lecturer on chemistry in the Royal In-

situation.—Mr. Davy remarks that, “All the Galvanic combinations analogous to the new apparatus of Mr. Volta, which have been heretofore described by experimentalists, consist (as far as my knowledge extends) of series containing at least two metallic substances, or one metal and charcoal, and a stratum of fluid.” And it has been generally supposed, that their agencies are, in some measure, connected with the different powers of the metals to conduct electricity. But I have found that an accumulation of Galvanic influence, exactly similar to the accumulation in the common pile, may be produced by the arrangement of single metallic plates, or arcs, with different strata of fluids.*

Some facts, which the author then relates, induced him to suppose “that the alternation of two metallic bodies with fluids, was essential to the production of accumulated Galvanic influence, only so far as it furnished two conducting surfaces of different degrees of oxidability; and that this production would take place, if single metallic plates could be connected together by different fluids, in such a manner that one of their surfaces only should undergo oxidation, the arrangement being regular.—On this supposition I made a number of experiments on different arrangements of single metals and fluids; and after many various processes, I was enabled to ascertain, that many of these arrangements could be made active, not only when oxidations, but likewise when other chemical changes were going on in some of their parts.”

Having made observations on the different combinations formed by single metallic plates and fluids, which he divides into three classes, the ingenious author then proceeds to state that “In all the single metallic piles constructed with cloths, the action is very transient: the decomposition of the acids, and of the sulphurets, is generally completed in a few minutes; and, in consequence, the Galvanic influence ceases to be evolved.” The arrangement of all the different series may, however (by means of an apparatus constructed after the ideas of Count Rumford), be made in such a manner as to give considerable permanency to their effects. This apparatus is a box, covered with cement incapable of conducting electricity, and composed of three pieces of mahogany, each containing grooves capable of receiving the edges of the different plates proper for composing the series. One half of these plates must be composed of horn, or glass, and the other half of metallic substances; and the conductors of electricity, and the non-conductors, must be alternately cemented into the grooves, so as to form water-tight cells.

“When the apparatus is used, these cells are filled, in the Galvanic order, with different solutions, according to the class of the combination; and connected in pairs with each other, by slips of moistened cloth, carried over the non-conducting plates.

“A combination of fifty copper-plates, arranged in this manner, with weak solutions of nitrous acid, or nitrate of ammoniac, and sulphuret of potash, gives pretty strong shocks, rapidly evolves gas from water, and affects the condensing electrometer.

“It does not lose its power of action for many hours; and, when this power is lost, it may be restored by the addition of small quantities of concentrated solutions of the proper chemical agents to the fluids in the different cells.

“From two experiments made on copper and silver, it would appear, that the single metallic batteries act equally well, when the metals made use of are slightly alloyed, and when they are in a state of purity.”

Many other curious facts have transpired on this interesting discovery; but, as they have not been hitherto applied to medical purposes (though we believe that *Galvanism* may be safely, and perhaps successfully, resorted to, in *paralytic* and other cases, where the muscles require excitement), we shall content ourselves with referring the curious reader to Dr. Fowler's *Essay on Animal Electricity*, 8vo.;—for a further account of Signor Volta's discovery, to the volume of the *Philosophical Transactions* above cited; and to the 4th volume of Mr. Nicholson's *Journal of Natural Philosophy*; and, for later discoveries, to the *Journals of the Royal Institution of Great Britain*, where the subject is perspicuously treated.

GAME-LAWS (*Encycl.*). The following is a short sketch of the laws, as they now stand (1802), relating to hares, partridges, pheasants, and other game.

The penalty for killing in the night a hare, partridge, or pheasant,—qualified or unqualified, is *§l.*

Any unqualified person exposing to sale a hare, partridge, pheasant, or other game, is liable to a penalty of *§l.*

If any hare, pheasant, partridge, or other game, be found in the shop, house, or possession of any poulterer, saleman, fishmonger, cook, or pastry-cook, or of any person not qualified in his own right to kill game, or entitled thereunto under some person so qualified, it shall be deemed an exposing thereof to sale.

For selling a hare, partridge, pheasant, or other game,—qualified or unqualified, *§l.*

Any unqualified person using tunnels or other engines, to kill or destroy a hare, partridge, pheasant, or other game, forfeits *§l.*

Any unqualified person keeping and using greyhounds, setting-dogs, lurchers, tunnels or other engines, to kill or destroy hares, partridges, pheasants, or other game, is liable to *§l. penalty*—the *§l. penalty* is either for keeping or using.

[Persons taking, killing, destroying, carrying, selling, buying, or having in their possession, any partridge, between the 1st of February and the 1st of September,—qualified or unqualified, *§l. 39 Geo. 3. c. 34.*]

For using greyhounds, lurchers, or setting-dogs*, to kill a hare, partridge, or pheasant,—unqualified, *§l.*

For killing a pheasant, between the 1st of February and 1st of October,—qualified or unqualified, *§l.*

[The information in the above cases must be laid within fix calendar months, before a justice of the peace, or by action of debt, bill, plaint, or information. The whole penalty to be given to the informer, with double costs, if brought on in the courts of Westminster.] Half to the informer and half to the poor.

For tracing in the snow, or shooting with a gun or long bow, a hare,—qualified or unqualified, imprisonment for 3 months, or fine 1*l.*

For using snares to take or kill a hare,—qualified or unqualified, imprisonment one month, or fine 10*s.*

[The information in the above cases must be laid before a justice of the peace within one year.]

The informer to be entitled to all costs and charges, and to half the penalty, the other half to be given to the poor of the parish.

Any game-keeper killing or taking a hare, pheasant, partridge, or other game, under colour of being for the use of the lord of the manor, and afterwards selling and disposing thereof without the consent of the said lord of the manor—upon conviction, on the complaint of such lord, and on the

* Greyhounds, lurchers, and setting-dogs, are the only dogs for keeping and using which the penalty of *§l.* is levied. But by another statute, a penalty not exceeding 20*s.* may be levied for keeping and using the above or any other dogs.

oath of one witness, before a justice, shall be committed to the house of correction for three months, and there kept to hard labour.

Any person who shall destroy, sell, or buy any hare, pheasant, &c. and shall in three months make discovery of any higher, chapman, carrier, innkeeper, alehouse-keeper, or victualler, that hath bought or sold, or offered to buy or sell, or had in their possession, any hare, pheasant, partridge, &c. so as any one shall be convicted; such discoverer shall be discharged of the pains and penalties hereby enacted for killing or selling such game, and shall receive the same benefit as any other informer.

Any justice of the peace, and lord within his manor, may take away any such hare, pheasant, partridge, &c. from any higher, chapman, innkeeper, victualler, or carrier, or any other person not qualified, which shall be found in his custody or possession.

Any person that shall knowingly and wilfully kill, take, or destroy, or use any gun, dog, snare, net, or other engine, with intent to kill, take, or destroy, any hare, partridge, or other game, in the night, viz. between the hours of seven at night and six in the morning, from the 12th of October to the 12th of February, and between the hours of nine at night and four in the morning, from the 12th of February to the 12th of October; or in the day-time on a Sunday or Christmas-day; shall forfeit for the first offence not exceeding 20*l.* nor less than 10*l.* For the second offence not exceeding 30*l.* nor less than 20*l.* For the third and every other subsequent offence, 50*l.*

[The information to be laid within one calendar month before a justice of the peace. The informer to be entitled to all costs and charges, and to half the penalty, the other half to be given to the poor of the parish.]

No person shall shoot with any cross-bow, hand-gun, or demihake, unless such person is really possessed of 100*l.* per annum, on pain of forfeiting 10*l.*

No person, of what estate or degree soever, shall shoot with, carry, keep, use, or have in his possession, any hand-gun, not being in the stock and gun of the length of one yard; or any hagbut, or demihake, not being in the stock and gun of the length of three quarters of a yard, on pain of forfeiting 10*l.*

Any person having 100*l.* per annum as above, may seize every such cross-bow, hand-gun, &c. being so deficient in length; but shall break and destroy them in 20 days after such seizure, on pain of forfeiting 2*l.*

No person shall command his servant to shoot with any cross-bow, hand-gun, hagbut, or demihake, at any deer, fowl, or other thing, except at a butt or bank of earth, on pain of forfeiting 10*l.*

N. B. Persons qualified to kill game, must be in possession of lands, tenements, or some other estate of inheritance, either in right of themselves or their wives, of the clear yearly value of 100*l.*—or for life, or lease of 99 years of 150*l.* per annum; other than the son and heir of an esquire, or person of a higher degree, or lord of a manor, or keepers of parks, chases, or free warrens.

The following is Lord Mansfield's opinion: "An unqualified person may go out to beat the hedges, bushes, &c. with a qualified person, and to see the game pursued or destroyed, provided the unqualified person has no gun or other engine with him for the destruction of the game, without being subject to a penalty."

The licences for killing game are under the following regulations:

By the 25 Geo. III. c. 50. and 31 Geo. III. c. 21. every person who shall use any dog, gun, net, or other engine, for

the taking or destruction of game (not acting as gamekeeper), shall deliver in an account in writing, containing his name and abode, to the clerk of the peace, and annually take out a certificate thereof; and every such certificate shall be charged with a stamp-duty of 2*l.* 2*s.* and 1*l.* 1*s.* making in the whole 3*l.* 3*s.*

Every deputation of a gamekeeper shall be registered with the clerk of the peace, and such gamekeeper shall annually take out a certificate thereof; which certificate shall be charged with a stamp duty of 10*s.* 6*d.* and 10*s.* 6*d.* making in the whole 1*l.* 1*s.*

Clerks of the peace delivering a certificate shall be entitled to 1*s.* for their trouble.

Every certificate to bear date the day when issued, and to continue in force until the 1st day of July then following.

Any person that shall use any greyhound, hound, pointer, setting-dog, spaniel, or other dog, or any gun, net, or engine, for taking or killing of game, without a certificate, is liable to a penalty of 20*l.*

If any gamekeeper shall, for the space of twenty days after appointment, neglect or refuse to register his deputation and take out a certificate thereof, he is liable to the penalty of 20*l.*

This act not to extend to the royal family.

If any gamekeeper, who shall have registered his deputation, and taken out a certificate thereof, shall be changed, and a new gamekeeper appointed in his stead, the first certificate is declared null and void, and the person acting under the same, after notice, is liable to the penalty of 20*l.*

Any person in pursuit of game, who shall refuse to produce his certificate, or to tell his name and place of abode, or shall give in any false or fictitious name or place of abode to any person requiring the same, who shall have obtained a certificate, is liable to the penalty of 50*l.*

The certificates are not to authorize persons to kill game at any time prohibited by law, nor give any person any right to kill game, unless such person shall be qualified so to do by the laws now in being; and if he is not qualified, although he may have such certificate, he is liable to the same penalties as if this act had not passed.

Witnesses refusing to appear on justice's summonses, or appearing and refusing to give evidence, forfeit 10*l.*

Penalties exceeding 20*l.* are to be recovered in any of his Majesty's courts of record at Westminster; and penalties not exceeding 20*l.* are recoverable before two justices, and may be levied by distress.

N. B. The above penalties go half to the king and half to the informer, if sued for within six months. 26 Geo. III. c. 82.

GANDERSHEIM, a town of Lower Saxony, in the duchy of Brunswick Wolfenbützel, with a celebrated muntery, 17 miles S.W. of Götting. Long. 18. 20. E. Lat. 51. 54. N.

GANDIA, a sea-port of Spain, in Valencia, with a small university, 55 miles N. of Alicante. Long. 0. 20. E. Lat. 39. 6. N.

GANDICOTTA, a town of the peninsula of Hindoostan, subject to the regent of Mysore, remarkable for a strong fortress, and a diamond mine near it. It is seated on the river Pennar, between Gooty and Cuddapa.

GANDINA, a town of Italy, in the Bergamasco, 10 miles N.E. of Bergamo.

GANGEA, or GANEA, a town of Persia, in the province of Erivan, 105 miles S. by E. of Tefflis. Long. 45. 50. E. Lat. 41. 10. N.

GANGELL, a town of Westphalia, in the duchy of Juliers, 12 miles S.E. of Ruremonde. Long. 5. 48. E. Lat. 51. 8. N.

GANGOTRI, a town of Thibet, on the Ganges, 138 miles N. of Delhi. Long. 76. 35. E. Lat. 33. 8. N.

GANGPOUR, a town of the peninsula of Hindoostan, in the country of Orissa, 226 miles S. of Patna. Long. 83. 57. E. Lat. 21. 25. N.

GANJAM, a town of the peninsula of Hindoostan, in one of the Northern Circars, subject to the English. It lies on the Bay of Bengal, between a river and the S.W. end of Chilka Lake. Long. 85. 20. E. Lat. 19. 22. N.

GANNAT, a town of France, in the department of Allier, 30 miles S. of Moulins.

GAOJA, a country of Africa, to the W. of Nubia. The inhabitants are said to be barbarous and uncivilized. It has a town of the same name, situate on a large lake. Long. 26° E. Lat. 16° N.

GAP, an ancient town of France, in the department of the Upper Alps, and lately a bishop's see. It was taken in 1692, by the Duke of Savoy, who burnt a great part of it. Gap is seated on the small river Bene, at the foot of a mountain, in which some mineral waters are found, 27 miles N. of Sisteron. Long. 6. 10. E. Lat. 44. 34. N.

GAPSAL, a town of Russia, in the government of Revel, 36 miles W.S.W. of Revel. Long. 60. 10. E. Lat. 59. 5. N.

GARACK, an island in the gulf of Persia, remarkable for the fine pearls fished upon its coasts. Long. 48. 0. Lat. 28. 15. N.

GARD, a department of France, including part of the late province of Languedoc. Nîmes is the episcopal town.

GARD, PONT DU, a Roman aqueduct, in France, nine miles N.E. of Nîmes, erected, it is supposed, by Agrippa, in the time of Augustus. It is 160 feet in height, and consists of three bridges rising above each other, and uniting two craggy mountains. The highest of these bridges has six arches, of great blocks of stone, without cement; the centre one has eleven; and the lowest (under which flows the Gardon, an inconsiderable, but rapid river) has 36. Lewis XIV. when he repaired, in 1699, the damages which this stupendous work had sustained by time, caused a real bridge, over which passengers now pass, to be constructed by the side of the lower range of arches. This aqueduct was built, in order to convey to Nîmes the water of the spring of Eure, which rises near Uzès.

GARDA, a town of Italy, in the Veronese, seated at the end of a lake of its own name, 17 miles N.W. of Verona. Long. 11. 4. E. Lat. 45. 36. N.

GARDELEBEN, a town of Germany, in the Old Marche of Brandenburg. It has a trade in hops and excellent beer, and is seated on the river Beise, 32 miles N. by W. of Magdeburg. Long. 11. 35. E. Lat. 52. 41. N.

GARDENS, FOR COTTAGERS. The following extract from an account of cottagers' gardens, in the county of Cambridge, by the Rev. James Plumtree, is published by the Society for bettering the Condition of the Poor.

"At Arrington, in the month of July, 1800," says Mr. Plumtree, "I observed on the church door a notice from the Earl of Hardwick, addressed to the cottagers and labourers of the parish, 'that premiums of one guinea and a half, one guinea, and half a guinea, would be given to the three persons of that description, who should appear to have taken the greatest care of their gardens, and to have raised and brought to perfection, in the course of the summer, the greatest quantities of peas, beans, carrots, turnips, cabbages, onions, or potatoes, in proportion to the extent of ground occupied.' The gardens were to be inspected by his lordship's gardener, and three other persons appointed for that purpose, as often, and at such times, as they might think proper; and

the premiums were to be adjudged on the 20th of October. Such persons as wished to be considered as candidates for the premiums, were previously to signify their intentions to the judges.

"A plan so well calculated to promote the industry, comfort, and resources of the cottager, and even of those candidates who should not be so fortunate as to gain the rewards, naturally excited curiosity; and on further enquiry it appeared that his lordship had instituted the same premiums in his other parishes of Wimple and Whaddon.

"When the time for adjudging the premiums was past, anxious to know the result, I made enquiries, and found that the plan, both as to external neatness, and the internal comfort and supply of their families, had fully answered. In order that these means of promoting the industry and comforts, and consequently improving the morals of the cottager, and rendering every village a pleasing scene of rural plenty and happiness, might be made known, and thereby the heads of other parishes be engaged to follow so benevolent an example, I inserted a statement of the above, with the names of the successful candidates, in the Cambridge Chronicle, for November 29, 1800.

"In the parish of Hinxton, in the same county, upon the first mention of these premiums, the principal land-proprietor immediately came into the plan, and gave notice that similar premiums would be distributed to the cottagers and labourers of that parish for the ensuing year. And as he and I purposed being two of the inspectors, I resolved to go over to Wimple, and see the gardens, and gain some further information respecting them.

"Accordingly, on the 18th of December, I went over to Wimple, and, accompanied by his lordship's gardener, visited the gardens of the successful candidates. All three of them lay together amongst others, fix in number, with a strong outward fence enclosing them, and divided from each other by young quick hedges, in a very thriving condition. Each garden might be about 16 poles; and, though it was so late in the season, and the principal crops were off the ground, yet the ground was in excellent order, and well stocked with cabbages, kale, &c. for winter vegetables. The potatoes and onions, of which each had a sufficient stock, were some of the finest I have seen this year. The cottages, to which these gardens belong, have been built within a few years by his lordship, and are of brick and very commodious; besides the garden, each has its pig-stye and other conveniences: a pond of water is near at hand. Even taste is displayed in these rustic scenes; and a honey-suckle, twining round a pole, formed an arch over the entrance into some of the gardens. We next visited the garden of another cottager, who, though he had not gained one of the premiums, had been distinguished for his industry. It was not above three poles of ground, but it was well stocked, and in good order.

"The garden of the cottager who gained the first premium at Arrington, was larger than those at Wimple. It might be about 20 poles. This had been kept in order by a very hard working man with a family of seven children; the eldest of which, a girl, was about 15 years of age; he used to work at it early and late. Besides a variety of other vegetables, he had got from it 50 bushels of potatoes, which at that time sold at 4s. per bushel. The gardens of the two other successful candidates, and others which I visited, were all in good order, and well stocked for the time of the year. As I thought I could not make a more acceptable present to these sons of industry, I took with me some of the *Information to Cottagers*, published by the society; a copy of which I gave at each cottage.

"Besides the encouragement given to the cottagers in their

gardens, he permits them to plant potatoes in his new plantations, and on the fallows, provided they dung the ground. One man from six loads of dung, had got 70 bushels of potatoes. Some waste ground by the road side had likewise been enclosed for the poor, which they sowed in what is called *lazy bed*. The method of doing this is, a space of eight feet wide is marked out for the bed, and then another two feet wide for the path, and so on. The potatoes or eyes, are laid on the sward, in alternate rows; the sward is then dug up from the path, and laid over the potatoes, and as they grow they are earthed up with the soil out of the path, which likewise serves as a drain, if the weather should prove wet.

"As I found it with difficulty that three persons were selected at Whaddon, deserving of the premiums, and that the gardens* were not so well worth seeing, I did not go thither; but was happy to find that a spirit of exertion began to be excited among the cottagers there, and they had promised better for the ensuing year.

"When the premiums had been awarded, the nine successful candidates, and six others (three from each of the parishes of Wimple and Arrington, recommended to Lord Hardwick's generosity on account of their industry), attended at church on the Sunday following, after which the gardener conducted them into the great hall, where his lordship distributed the rewards, with a gratuity to each of the others, with some good advice on the occasion; recommending industry and virtue in general, and promising his friendship so long as they were deserving of it.

"The advantages arising from this plan, appear to be so very obvious, that it seems scarcely necessary to enumerate them. For the sum of three guineas in a parish, a number of families; perhaps all the cottagers, are excited to industry. A valuable stock of vegetables is produced, both for summer and winter consumption; and great assistance given towards the keep of a pig. Besides the good accruing to the cottager in thus finding useful and innocent employment for his leisure hours, and in keeping him from the alehouse, an example is set to his family; which will probably be trained up, under his care, to follow the same useful employment throughout life. At the same time the cottager must derive no small degree of satisfaction, from the idea that he is become the object of the attention, and commendation, of his richer neighbour.

"The only difficulty which seems to occur, is in forming a correct estimate of the comparative merits of the gardens. This, however, I think is more in appearance, than in reality. I do not apprehend that the sum total of the excellence will often be so nicely balanced as to make it difficult. The requisites, in the judges, seem to be *science* and *impartiality*. The first of these was, most unquestionably, possessed at Wimple, and there is no cause to doubt of the existence of the other. At Hinxton, however, to the head and under gardener, we have added a very honest farmer and ourselves; thinking that some additional advantage might accrue from our attention; and from our being able to judge in some degree of the other estimates, by going our rounds, keeping an eye to the cottager, and on his cottage, his family, and his garden; and thus getting an insight into the real merits of our poorer neighbours.

"The method of estimating seems to be, to measure the ground of each candidate; and, at proper times, to go round, and value the respective crops. He, who produces most in

proportion to his ground, is the most deserving. A paper divided into columns, or a small memorandum book, with the name of the candidates at the top of each column or page, and their respective portions of ground, should be provided, and the memorandums and estimates placed under each. Two things seem especially necessary to demand attention; one, that the visits should be uncertain, in order that the cottager may be obliged to be always prepared; and the other, that the cottager may have the power to invite a visit, in order that his crops may be seen at the time when he himself thinks them in perfection."

GATEHOUSE, a considerable village in Kirkcubrightshire, at the mouth of the river Fleet. Here is a cotton-mill; and, sloops come up the river, within a short distance of the town. It is nine miles N.W. of Kirkcubright.

GAVARDO, a town of Italy, in the Bresciano, seated on the Weiße, seven miles W. of Lake Garda. Long. 10. 9. E. Lat. 45. 40. N.

GAUDENS, Str. a town of France, in the department of Upper Garonne, seated on the Garonne, eight miles N.E. of St. Bertrand. Long. 0. 56. E. Lat. 43. 1. N.

GAVEREN, or **WAVAREN**, a town of Austrian Flanders, seated on the Scheldt, eight miles S. of Ghent. Long. 3. 51. E. Lat. 50. 56. N.

GAVI, a town of Italy, in the territory of Genoa, seated on the Lemo, 19 miles N.W. of Genoa. Long. 8. 57. E. Lat. 45. 40. N.

GAUTS, or **INDIAN APPENNINES**, a stupendous wall of mountains, extending from Cape Cormorin, the S. extremity of Hindoostan, to the Tapti, or Sûrat River, at unequal distances from the coast; in one short space only, it approaches within six miles, the common distance is 40, and it seldom exceeds 70. They rise abruptly from the low country, called the Concan, or Cockum; supporting, in the nature of a terrace, a vast extent of fertile and populous plains, which are so elevated, as to render the air cool and pleasant. This celebrated ridge does not terminate in a promontory when it approaches the Tapti; but, departing from its meridional course, it bends eastward, in a wavy line, parallel with the river; and is afterwards lost among the hills, in the neighbourhood of Burhampour. In its course along the Tapti, it forms several passes, or descents (that is Gauts, according to the original import of the word, which means a landing-place), toward that river.

GEARON, or **JARON**, a town of Persia, in Faristan, in whose territory the best dates of Persia are produced. Long. 51. 17. E. Lat. 28. 15. N.

GEFLE, the capital of the province of Gefrike, in Sweden, seated on three branches of a river of the same name, which begins to be navigable here, and falls, in a short distance, into a bay of the Baltic. It is the most commercial town in this northern part of Sweden; and its exports are principally iron, pitch, tar, and planks. It is 55 miles N. by W. of Stockholm. Long. 17. 0. E. Lat. 63. 0. N.

GEGENBACH, a free imperial city of Suabia, and under the protection of the house of Austria. It is seated on the Kinzia, 12 miles S.E. of Strasburg. Long. 8. 2. E. Lat. 48. 24. N.

GEHMEN, a town of Westphalia, situate on the Aa, 16 miles N.E. of Wesel. Long. 6. 43. E. Lat. 51. 36. N.

* In a separate sheet is added a cottager's garden calendar; to inform and assist those cottagers who wish to make the most of their gardens, for the benefit of themselves and their families. Some of the articles are directed to a little profit by sale. It may be had gratis, at Hatchard's, Piccadilly, London, by the members of the Society.

† There were 14 candidates at Wimple, 12 at Arrington, and 10 or 11 at Whaddon.

GELEKIRCHER, a town of Westphalia, in the duchy of Juliers, eight miles N.W. of Juliers. Long. 5. 56. E. Lat. 51. 2. N.

GEILLDORF, a town of Suabia, near the river Kocher, with a castle belonging to the lords of Limpurg.

GEISLINGEN, an imperial town of Suabia, 17 miles N.W. of Ulm. Long. 10. 3. E. Lat. 48. 36. N.

GEISMAR, a town of Germany, in the principality of Hesse, 14 miles N.N.W. of Cassel, and 22 W. of Gottingen. Long. 8. 57. E. Lat. 51. 19. N.

GEMAPPE, a village of Austrian Hainault, three miles W. by S. of Mons, famous for a victory which the French obtained here over the Austrians, Nov. 5, 1792; in which the carnage on both sides was so great, that three coal-pits adjacent were filled up with the dead bodies of men and horses.

GEMBOLOURS, a town of Austrian Brabant, with an ancient abbey. Don John of Austria gained a battle here over the Dutch in 1578; and it was twice burnt down, in 1628 and 1712. It is seated on the Orneau, 22 miles S.E. of Brussels. Long. 4. 51. E. Lat. 50. 37. N.

GEMINIANI, Sr. a town of Tuscany, in the Florentino, seated on a mountain, in which is a mine of vitriol, 25 miles S.S.W. of Florence.

GEMMINGEN, a town of Germany, in the palatinate of the Rhine, 30 miles E. of Philippsburg. Long. 9. 13. E. Lat. 49. 6. N.

GEMUND, an imperial town of Suabia, with a manufacture of chaplets or beads. It was taken by the French in August 1796; and is seated on the Reims, 30 N. by W. of Ulm. Long. 9. 48. E. Lat. 48. 48. N.

GENAP, a town of Austrian Brabant, with an ancient castle, seated on the Dyle, 15 miles S.E. of Brussels. Long. 4. 40. E. Lat. 50. 40. N.

GENEVOIS, a duchy of Savoy, of which Geneva and its territory were formerly a part. Annecy is the capital.

GENGENBACH, a town of Suabia, 10 miles S.E. of Straßburg. Long. 7. 53. E. Lat. 48. 28. N.

GENGOUX DE ROYAL, Sr. a town of France, in the department of Saône and Loire, remarkable for its excellent wines. It is seated at the foot of a mountain, 17 miles S.W. of Chalons. Long. 4. 43. E. Lat. 46. 37. N.

GENIEZ, Sr. a town of France, in the department of Aveiron, 24 miles N.E. of Rhodéz. Long. 3. 0. E. Lat. 44. 35. N.

GENIS, a town of Savoy, seated on the Guier, 12 miles W. of Chambery. Long. 5. 30. E. Lat. 45. 40. N.

GENLIS, a town of France, in the department of Aisne, 12 miles S. of St. Quentin.

GENOA, a territory and republic of Italy, extending along that part of the Mediterranean called the gulf of Genoa, 152 miles; but its breadth is very unequal, being from eight to twelve miles. Where it is not bounded by the sea, it is bordered from W. to E. by Piedmont, Monterrat, Milan, Placentia, Parma, Tuscany, and Lucca. It is populous, well cultivated, and fertile near the sea; but the inner parts are mountainous, and barren in several places, having neither trees nor grass upon them. The corn grown is insufficient for its own consumption; but this is amply compensated by its vineyards, and abundance of excellent fruits, particularly lemons, oranges, pomegranates, almonds, and figs; and its mulberry and olive trees are innumerable.

GENTIAH, a town of the kingdom of Aflam, 370 miles E. of Patna. Long. 92. 10. E. Lat. 25. 10. N.

GEOGRAPHY (*Encycl.*). In the British Magazine for 1800 are the following Observations on the Geography of Homer's *Odyssey*, which are extremely curious and interesting.

The accidental geography of Homer seems never to have been examined with due accuracy, and the received opinions concerning it are liable to very strong objections. The learned Abbé Banier enquires *qui est ce qui peut dire où étoient les Cimmériens d'Homère, et l'Île de Calypso?* The Roman writers, whose national vanity arrogated the entire western geography of Homer to Italy and Sicily, may be considered as the predecessors of Rudbeck; who, perhaps with equal reason, has drawn the whole of that geography to Scandinavia.

For the sake of the general reader we shall omit the original passages, and content ourselves with Mr. Pope's translation of the *Odyssey*. Hence it will appear; 1. That Ulysses leaving Troy attacked the *Cicones*, beneath the mountain of Iliarus, in Thrace. Book ix. v. 41. *et seq.*

The winds from Ilion to the Cicon's shore,
Beneath cold Iliarus, our vessels bore;
We boldly landed on the hostile place,
And sack'd the city, and destroy'd the race.

2. That a violent north wind drove them down on *Cythera*, an island at the south-eastern corner of Peloponnesus. Book ix. v. 77. *et sequent.*

Strong was the tide, which by the northern blast,
Impell'd our vessels on Cythera cast.

3. That the tempest, in *ten days*, conveyed him to the coast of the *Lotophagi*, in the middle of the northern shore of Africa.—*Ibid.* v. 95. *et sequent.*

4. From the land of the *Lotophagi* they were borne along unknown coasts, and through unexplored seas, till they came to the land of the *Cyclops*, and the island of *Lachæa*. Verse 119, &c.

V. 133.—Oppos'd to the Cyclopean coasts, there lay
An ile, whose hills their subject fields survey;
Its name Lachæa, crown'd with many a grove,
Where savage goats thro' pathless thickets rove.

It would be difficult in this chorography to discover any resemblance of Sicily. The land of the *Cyclops* appears evidently to belong to the continent; and the general geography of the voyage must lead us to infer that it was in that part of Africa where Carthage was afterwards to bid defiance to Rome.

5. From the land of the *Cyclops*, Ulysses returned to the island of *Æolus*, probably one of the *Lipare*, on the western coast of Sicily; and in ten days of rapid navigation with a favourable wind, the special and miraculous gift of *Æolus*, they discovered *Ithaca*. Book x. v. 31.

6. Driven back to the island of *Æolus*, v. 59, the tempest still rages from the east; and in six days and nights drives them to the shore of the *Leirigons*, and the city of *Lamos*, in all appearance situated in Spain.

7. The tempest further impels them to the island of *Circe*, seemingly one of the Fortunate Islands, or what are now called the *Canaries*. That the island of *Circe* belonged to the Fortunate group, is positively asserted by several ancient writers.

8. Hence, Book xi. he proceeded to the land of the *Cimmeri* in one day, by the potency of *Circe's* magic. All the ancient traditions bear that his voyage lay along Portugal (where stood *Ulyssipona*); and thence even to Germany and Caledonia, where were the altars of Ulysses (*Tacit. Germ. chap. 3.*) These circumstances, however fabulous, evince the extensive ideas entertained by the ancients concerning the navigation of Ulysses.

9. Upon leaving the island of Circe, Ulysses endeavours to navigate homewards, by the rocks of the *Syrens*, and Scylla and Charybdis. The Syrens in all appearance dwelled in the islands styled the *Baleares*, now Majorca and Minorca.

The strait of Scylla and Charybdis was certainly between *Cosica* and *Sardinia*; for,

10. Long after passing that strait he arrived at *Trinacria*, which all grant to be Sicily; whereas if we take Scylla and Charybdis in the modern acceptation, when he had passed them he must in fact have passed Trinacria; instead of coming to it afterwards. An additional argument also here arises, that the Cyclops were not inhabitants of Sicily, for Homer mentions Trinacria as the island where the flocks of Apollo pastured, and says not one word of the Cyclops.

11. The ship leaving Trinacria is wrecked, and a *south* wind drives Ulysses back, through the strait of Scylla and Charybdis, to *Ogygia*, the island of Calypso, probably one of the *Hierres* on the coast of France.

12. In seventeen days and nights he reaches the coast of Phæacia. Book v. v. 345.

And now rejoicing in the prosperous gales,
With beating heart Ulysses spreads his sails;
Plac'd at the helm he sat, and mark'd the skies,
Nor clos'd in sleep his ever-watchful eyes.
There view'd the Pleiads, and the northern team,
And great Orion's more refulgent beam;
To which, around the axle of the sky,
The bear, revolving, points his golden eye;
Who shines exalted on th' ethereal plain,
Nor bathes his blazing forehead in the main.
Far on the left those radiant fires to keep,
The nymph directed, as he sail'd the deep.
Full seventeen days he cut the foamy way,
The distant land appear'd the following day;
Then swell'd to sight Phæacia's dusky coast,
And woody mountains, half in vapours lost,
That lay before him, indistinct and vast,
Like a broad shield amid the wat'ry waste.

From Phæacia Ulysses sail'd to Ithaca, in *one night*. The island of Ogygia has been absurdly placed on the east of Italy, at about twice the distance of Phæacia from Ithaca: whereas Ulysses employed seventeen days and nights, even with a prosperous gale, to sail from Ogygia to Phæacia, and only one night (Book xiii. v. 112) to pass from Phæacia to Ithaca!

Some observations on the state of geographical knowledge, at that remote period, here naturally suggest themselves. There are two errors which have greatly impeded the progress of our knowledge of ancient geography. The first, and the most destructive of just ideas on the subject, is that of those who have too far extended the knowledge of the ancients; the second, and by far the most rational, is that which restricts it within narrow bounds.

Sir Isaac Newton has attempted very much to reduce the Pagan chronology, by calculations from celestial appearances, which M. Bailly has since mathematically demonstrated, in his *Astronomie Ancienne*, are anterior by four or five hundred years to the period ascribed by our great English philosopher. The chief cause of Sir Isaac's failure was his approximation of celebrated events, while he seems to forget that tradition will preserve equally fresh a remote event of vast consequence, or of striking splendour, with a more recent occurrence of inferior moment. Thus, in the darkness of night, a beacon at the distance of thirty miles may display a similar appearance to that of a torch at the distance of three.

In like manner, if we attempt to compress the pristine, precise notions of geography, within too narrow and connected limits, we may fall into gross errors. The Phœnicians, and other nations on the Mediterranean sea, ever adventuring in quest of fresh sources of gain, or impelled by storms, and the prevalence of certain winds, could not fail, even in very early times, to discover every region adjacent to that vast basin. Nature had opened to them, as it were, a highway, which they could hardly help exploring to its furthest extremity. The *Tharjish* of Solomon is generally allowed to have been the *Tartessus* of the ancients near Cadiz, the port whence the silver from the Spanish mines was brought to the oriental world. But not to waste time in learned discussion, it is well known that the Phœnicians had, many ages before the days of Homer, made numerous discoveries in the west of Europe. Of these discoveries, when retailed by tradition, several confused notions must have been formed. Homer, certainly no stranger to Phœnician science, and desirous to enrich his poem with the new and the marvellous, has no doubt availed himself of their furthest discoveries; and the confined limits within which we restrict the voyage of Ulysses, seems, in the first place, to have proceeded from the vanity of the Roman writers; and, in the next place, from the complete inattention which the moderns have paid to the subject.

GEORGE, ST. (*Encycl.*). To what has been said in our original article, we wish to add the following curious disquisition on the figure of St. George, the patron of England, as it is found on the coins of Russia. See plate 33.

St. George, the patron-saint of England, and of the order of the Garter, is much revered in Russia, and his figure occurs in all the churches. He is represented as usual, riding on a horse, and piercing a dragon with his lance. This same device also forms part of the arms of the Russian sovereign, and is observed upon several of the coins. As most persons endeavour, if possible, to derive every custom and allusion from their own country, some of the English historians have conjectured, that Ivan Vassilievitch the Second, being presented with the Garter by Queen Elizabeth, assumed the George and the Dragon for his arms, and ordered it to be stamped upon the current money. But this supposition is erroneous, as it by no means appears, that the Tzar was created a knight of the Garter; and it is certain that the sovereigns of Moscow bore this device before they had the least connection with England; for the arms of Moscow are thus described by Chancellor, the first Englishman who discovered Russia, as being affixed to a dispatch sent in 1554, from Ivan Vassilievitch to Queen Mary:—"This letter was written in the Moscovian tongue, in letter much like to the Greeke letters, very fair written in paper, with a broad seale hanging at the same, sealed in paper upon waxe. This seale was much like the broad seale of England, having on the one side the image of a man on horseback in complete harness fighting with a dragon." Hackluyt, vol. i. p. 255.

The Russian antiquaries find great difficulty in endeavouring to ascertain the origin of St. George, and his first introduction into their country.

Among a list of the Russian coins accompanied with engravings, published by Le Clerc, are several of a very early date, which represent the figure of a horseman spearing a dragon: one particularly of Michael Androvitz, which appears to have been struck in 1305, 40 years before the institution of the order of the Garter. From this period numerous Russian coins are successively distinguished by the same emblem. Another, struck in the reign of Vassili Vassilievitch in the 15th century, exhibits also the coarse figure of a man on horseback piercing a serpent or a dragon: of which device

a learned antiquary* has ingeniously given the following solution. The reign of Vasilii Vasilievitch was an epoch of great troubles and intestine dissensions between the Great Duke and his relations. During these contests he was deposed and imprisoned, and his eyes were put out; but having regained possession of the throne, he ordered the money to be impressed with the figure of a man on horseback piercing a serpent, as an emblem of ingratitude punished and rebellion defeated. Soon after this period the succeeding great dukes used this device for their arms, instead of the custom which before prevailed of adopting the head of the saint by whose name they were baptized. About the beginning of the seventeenth century, wings being added to the serpent, it was changed into a dragon, and the knight on horseback into St. George. But this is conjecturing too curiously, and seems too far-fetched a solution for so barbarous an age. It is far more probable, that the Russians received the image of St. George and the dragon either from the Greeks or from the Tartars, by both of whom he was much revered; by the former as a Christian saint and martyr, and by the latter as a prophet, or a deity. With respect to the Greeks, we know from history that in the fourth or fifth century he was much worshipped amongst them; and that, afterwards, the crusaders, during their first expedition into the Holy Land, found many temples erected in his honour. The Russians, therefore, who were converted to Christianity by the Greeks, certainly must have received at the same time a large catalogue of saints, which made an essential part of the Greek worship, and we have no reason to imagine that St. George was omitted.

In a villa of Prince Dolgorucki, near Moscow, is an old basso-relievo of St. George and the dragon, found in a ruined church at Interemen, in the Crimea; it had a Greek inscription almost erased, but the words *ΑΙΩΟ ΤΕΟΡΡΟΟ*, or St. George, and the date 1330, were still legible. As it appears from this basso-relievo that he was worshipped in the Crimea so near the court of Russia, when the great dukes resided at Kiof, his introduction into that country is easily accounted for.

Notwithstanding, however, the probability of this opinion, it is very likely that the Russians received from the Tartars the image of a horseman spearing a serpent, as it is represented upon their most ancient coins, and which formed a part of the great duke's arms towards the beginning of the sixteenth century. And first, with respect to their coins: the Russians had no coins before they were conquered by the Tartars; and soon after they were brought under the Tartar yoke, they struck money: the first Russian coins bear a Tartar inscription; afterwards they have Tartar letters on one side, and Russian characters on the other; and there is still pre-

served in the cabinet of St. Peterburgh, a piece of money, exhibiting a horseman piercing a dragon, with the name of the great duke in Russian, and on the reverse a Tartar inscription.

With respect to the arms, Herberstein, in his account of his embassy to Moscow in 1718, under Vasilii Ivanovitch, has given a wooden print of that prince, at the bottom of which are engraved his arms, representing a naked man on horseback[†] piercing a serpent with his lance. See fig. A. The equestrian figure in this device has a Tartar-like appearance, and is so coarse and rude, that it seems to have been derived from a people in a far more uncivilized state of society than the Greeks: add to this, as the Greeks always represented St. George clad in armour, what could have induced the Russians, if they had adopted this emblem from them, to have figured the horseman naked?

Shall we conclude, therefore, that the Tartars were not unacquainted with an emblem similar to that of St. George and the Dragon? In proof of this opinion, we may venture to remark, that the story of a saint or a deity spearing a dragon was known over the east: that among the Mahometans (see Herbelot Biblioth. Orientalis, article Gergis), a person called Gergis or George, under a similar figure, was much revered as a prophet; and that similar emblems have been discovered among many barbarous nations of the east. Whether these nations took it from the Greeks, or the latter from them, is a matter that cannot be ascertained; for with respect to the real existence of such a person as St. George, no positive proofs have ever been advanced.

But whether we conclude that the Russians received the emblem of St. George from the Greeks, or from the Tartars, it will still be difficult to reconcile how under Vasilii Ivanovitch the arms of the great dukes exhibited a naked man on horseback spearing a dragon, and under his son, Ivan Vasilievitch II. the horseman is represented in armour. But perhaps we may reconcile these two opinions by supposing, that the naked man on horseback, spearing a dragon, is the Tartar emblem; and the knight in complete armour (which is evidently the figure of St. George) was adopted as the arms of the great dukes, and not improbably introduced by Ivan Vasilievitch II. in compliment to his grand-mother, Sophia, a Greek princess.

Since this period, the emblem of St. George and the dragon has uniformly been represented on the reverse of Russian coins, as may be seen by the engraving of a rouble of the late Emperors, Catharine II. See fig. B.

Although any enquiry into the origin of St. George, and his introduction into England, is foreign to the present purpose, yet it may be observed, that amongst us several contradictory opinions have been held of St. George; and a whimsical controversy has arisen, whether the patron of England

† In una parte hominis nudi equo insidentis, et draconem hastâ ferientis imaginem habet; in alterâ verò parte, nomen magni ducis exprimitur. Herberstein Mosc. Descr. p. 157.

‡ The arguments brought by the ingenious Mr. Pegge to ascertain the existence and martyrdom of St. George, will serve equally to prove the existence of St. Januarius, or any other saint in the Roman Calendar. "We may depend upon it," he says, "that though at this distance of time we can recover so few particulars of St. George's story, and can arrive at so little certainty about the circumstances of it; yet the adventurers in the crusades undoubtedly regarded him as a real person, a most glorious and illustrious martyr. They found his name in the calendars; they met with various places denominated from him; they frequented his tomb and heard him invoked, and heard much of his apparitions; they saw churches and monasteries dedicated to him, and even received, as they thought, seasonable and special assistance from Heaven, through his mediation; and lastly, not to mention his relics, they could not but observe proper services appointed for him in the Greek and Roman Liturgies. After all which, it is not possible that our ancestors, on their return from the East, and in particular in the reign of King Edward III. should deem of him otherwise, than as having been once a true man, and more than an ideal figure of the brain." See Pegge's Observations on the History of St. George, in the fifth vol. of the Archaeologia, p. 5.

was a real or imaginary personage. Some are of opinion, that this history is an allegory; others maintain that the device is borrowed by the Christian church from the ancient story of Perseus and the sea-monster, of Bellerophon and the Chimera, or of Apollo and the serpent Python, or from some Egyptian hieroglyphics, or from charms and amulets worn by the Pagans*; others have traced his legend from the history of George† of Cappadocia, the Arian archbishop of Alexandria. Amongst the authors who have written upon this subject with the greatest success, must not be omitted, Mr. Byrom (Miscellaneous Poems, vol. I. p. 100), who has composed a metrical rhapsody addressed to Lord Willoughby, president of the Antiquarian Society, in which he endeavours to prove that St. George is a corruption of St. Gregory; and to use his own words:—

Now, my lord, I would ask of the learn'd and laborious,
If Ge-orgius bent a mistake for Gregorius?
In names so like letter'd it would be no wonder,
If hasty transcribers had made such a blunder;
And mistake in the names, by a flip of their pen,
May, perhaps, have occasion'd mistake in the men.
That this has been made, to omit all the rest,
Let a champion of yours, your own Selden attest;
See his book upon titles of honour—that quarter
Where he treats of St. George, and the knights of the
Garter.

And again:

This, my lord, is the matter—the plain simple rhymes
Lay no fault; you perceive, upon Protestant times:
I impute the mistake, if it should be one, solely
To the pontiffs succeeding, who christen'd wars holy;
To monarchs who, madding around their round tables,
Prefer'd, to conversion, their fighting and fables:
When soldiers were many, good Christians but few,
St. George was advanc'd to St. Gregory's due.
One may be mistaken—and therefore would beg
That a Willis, a Stukely, an Ames, or a Pegge,
In short, that your lordship, and all the fam'd set,
Who are, under your auspices, happily met
In perfect good humour—which you can inspire,
As I know by experience—would please to enquire,
To search this one question, and settle, I hope;
Was old England's old patron, a knight, or a pope?

In opposition to these opinions, several authors have entered the lists; particularly Heylin, Selden, and Fuller; and lately, Mr. Pegge endeavours to rescue this saint from annihilation, and to prove, at the same time, that he was a different personage from St. Gregory. But unfortunately for the arguments of the learned antiquarian, Mr. Byrom's treatise, which he opposes, is written in verse with so much ease, humour, and whimsical rhyming, that the reader is absolutely almost divested of his judgment, and with difficulty is prevented by the most weighty reasons from siding with the poet, who, instead of dull and dry disquisitions, treats us with much wit, couched in an easy flow of doggerel metre. However, after reading all (if any one can have patience† to read all) the disquisitions upon this subject, the reader retires without being convinced, or without yielding absolutely to any other

opinion than this, that the story of St. George is immersed in fable, and lost amid the uncertainty of ancient lore.

GERBSTADT, a town of Upper Saxony, 30 miles S.W. of Dessau, and 36 S. of Magdeburg.

GERMANS, Str. a borough in Cornwall, with a market on Friday. It was once the largest town in the county, and a bishop's see. What remains of the cathedral is used as the parish-church; and near it is the priory. The town now confists chiefly of fishermen's cottages, but is governed by a mayor, and sends two members to parliament. It stands near the sea, 10 miles W. of Plymouth, and 224 W. by S. of London. Long. 4. 24. W. Lat. 50. 22. N.

GERMAIN-LAVAL, Str. a town of France in the department of Rhone and Loire, remarkable for excellent wine. It is 18 miles S. of Roanne, and 225 S.E. of Paris. Long. 4. 2. E. Lat. 45. 50. N.

GERMAN DRAMA. See **DRAMA** in this Supplement.

GERMANO, Str. a town of Naples, in Terra di Lavoro, at the foot of Mount Cassano, and belonging to an abbey at the top of that mount. Long. 13. 59. E. Lat. 41. 13. N.

GERMERSHEIM, a town of Germany, in the palatinate of the Rhine, situate near the Rhine, five miles W. of Philipburg. Long. 17. 19. E. Lat. 49. 10. N.

GERMS, a town of the archduchy of Austria, 62 miles W.N.W. of Vienna. Long. 14. 57. E. Lat. 48. 32. N.

GEROLDSTEIN, a town of Westphalia, situate on the Kill, 24 miles N. of Treves. Long. 6. 19. E. Lat. 50. 49. N.

GERS, a department of France, which includes the late provinces of Gascony and Armagnac. It has its name from a river that waters Auch and Lectoure, and falls into the Garonne, above Agen. Auch is the capital.

GERSAU, a town of Switzerland, on the N. side of the lake of Schweiz, at the foot of the Rigi. It is a republic, the smallest in Europe. Its territory is two leagues in length and one in breadth. It contains 1000 inhabitants, who have their general assembly of burgesses, their landamman, council of regency, courts of justice, and militia. Gersau is composed entirely of scattered houses and cottages, of a very neat and picturesque appearance. The inhabitants are much employed in preparing silk for the manufacture at Basle. This republic is under the protection of the cantons of Lucern, Uri, Schwitz, and Unterwalden; and, in case of war, furnishes its quota of men. Gersau is 12 miles S.W. of Schwitz.

GERTRUDENBURG, an ancient town of Dutch Brabant, one of the principal bulwarks of the Dutch. It has a good harbour on the Maese, which here expands into a large lake, called Bies Bosch. It has been often taken, the last time by the French in 1795. It is 10 miles N. of Breda. Long. 4. 52. E. Lat. 52. 44. N.

GERUMENHI, an ancient town of Portugal, in Alentejo, with a strong castle; but was taken, in 1662, by the Spaniards. It is seated on a hill, near the river Guadiana, 18 miles below Badajoz.

GESEKE, a town of Westphalia, seated on the Weyck, eight miles from Lippe.

GESTRIKE, a province of Sweden, bounded on the N. by Helsingia, on the E. by the gulf of Bothnia, on the S. by Upland, and on the W. by Dalecarlia. It is diversified by forests, rocks, hills, and dales, pasture and arable land, lakes

* See Pettingal's ingenious Dissertation on the Original of the Equestrian Figure of the George and of the Garter.

† See Gibbon's History of the Decline and Fall of the Roman Empire, vol. II. p. 404, where the history of George of Cappadocia is investigated with great judgment and learning.

‡ Heylin's Historie of that most famous Saint and Soldier of Christ Jesus, St. George of Cappadocia, in quarto, contains 426 pages, printed very closely.

and rivers; and these beauties are much heightened by the Dam, the finest river in Sweden, which meanders through the whole extent of the province.

GEVAUDAN, a late territory of France, in Languedoc, bounded on the N. by Auvergne, on the W. by Rouergue, on the S. by the Cevennes, and on the E. by Velay. It is a mountainous, barren country; and now forms the department of Lozere.

GEX, a town of France, in the department of Ain, noted for excellent cheese. It is seated at the foot of Mount St. Claude, between the Rhone, the lake of Geneva, and Switzerland, 10 miles N.W. of Geneva. Long. 6. 1. E. Lat. 46. 20. N.

GEZIRA, a town of Diarbeck, in an island formed by the Tigris, 70 miles N.W. of Mouful. Long. 40. 50. E. Lat. 36. 36. N.

GEZULA, a province of Morocco, which is very productive, and contains mines of iron and copper. The inhabitants are numerous, and considered as the most ancient people of Africa: they live in tents, and are so independent, that they are rather the allies than the subjects of the emperor of Morocco.

GHANAH, or **GHINNAH**, a town of Cashna, seated between a lake and the river Niger, which is here called Neel-il-Abeed, or the Nile of the Negroes. It is 90 miles N.E. of Cashna, and 208 S. of Agadez. Long. 13. 12. E. Lat. 15. 55. N.

GHERGONG, a city and the capital of the kingdom of Affam. It is seated on a river which runs, in a short distance, into the Burrampooter, 400 miles N.E. of Calcutta. Long. 93. 15. E. Lat. 25. 55. N.

GHIZNI, or **GAZNA**, a town of Hindoostan Proper, in Cabul, once the capital of a powerful empire of the same name. It is called the second Medina, from the great number of illustrious persons who have been interred there. It is 54 miles S. of Cabul, and 150 E. of Candahar. Long. 68. 20. E. Lat. 16. 12. N.

GHOORBOND, a town of Hindoostan Proper, in the country of Cabul, 42 miles N.W. of Cabul. Long. 67. 52. E. Lat. 34. 55. N.

GIBBON (Edward), a celebrated English historian, was born at Putney in Surrey, on the 27th of April, 1737. He was the first-fruit of the marriage of Edward Gibbon, esq. and Judith Porten, the youngest daughter of a merchant in London. Mr. Gibbon appears to delight in tracing his pedigree from John Gibbon architect to King Edward III. who possessed lands in the hundred and parish of Rolvenden, in the district which is now called the *Weald* of Kent. In that district the elder branch of the family still adheres to its native soil, without much increase or diminution of property; but the fortunes of the younger branch, from which our historian sprang, were fluctuating.

So feeble was he, and so precarious his life during his childhood years, that at the baptism of each of his brothers (five in number) his father successively repeated the name of Edward, that, in case of the death of the eldest, this patronymick appellation might still be perpetuated in the family. His brothers and a sister died in their infancy; and, in terms of affectionate gratitude, he attributes his own preservation to the more than maternal care of a maiden aunt, his mother's eldest sister.

At the age of seven years he was delivered into the hands of Mr. John Kirby, who exercised, about eighteen months, the office of his domestic tutor; but he afterwards was sent to Kington-upon-Thames, to a school of seventy boys kept by Dr. Woodeson. He does not represent himself either as happy or as having made great progress at that school. The want of strength and activity disqualified him for the sports of

the field; his companions reviled him for the fins of his *Tory* ancestors; and his studies were frequently interrupted by sickness. After passing nearly two years at Kington, he was, in Dec. 1747, called away by the death of his mother. By this time he was well acquainted with Pope's *Homer*, the Arabian Nights Entertainments, Dryden's *Virgil*, and a translation of Ovid's *Metamorphoses*; and the entertainment which he received from these books gave him a taste for desultory reading.

After living a year with his maternal aunt, during which period he read many books on religious subjects too deep for the comprehension of a boy, he was in January 1749 entered at Westminster school, of which Dr. John Nicoll was then head master. "There (says he) in the space of two years, interrupted by danger and debility, I painfully climbed into the third form; and my riper age was left to acquire the beauties of the Latin and the rudiments of the Greek tongue. Instead of audaciously mingling in the sports, the quarrels, and the connections of our little world, I was still cherished at home under the maternal wing of my aunt, who now lived in College-street; and my removal from Westminster long preceded the approach of manhood."

He was first carried to Bath for the recovery of his health; then to Winchester, where he lived in the house of a physician; then to Bath again, where he read with a clergyman some odes of Horace and some episodes of Virgil; after which an unsuccessful trial was made to renew his attendance at Westminster school. "It might now be apprehended (says he) that I should continue for life an illiterate cripple; but as I approached my sixteenth year, Nature displayed in my favour her mysterious energies: my constitution was fortified and fixed; and my disorder, instead of growing with my growth, and strengthening with my strength, most wonderfully vanished." In consequence of this he was sent to Oxford; and before he had accomplished his fifteenth year, was, on April 3, 1752, matriculated a gentleman-commoner of Magdalen College, the tutors of which he represents as wholly regardless of his morals or his studies. Speaking of the best he says, "No plan of study was recommended for my use; no exercises were prescribed for his inspection; and at the most precious season of youth, whole days and weeks were suffered to elapse without labour or amusement, without advice or account." His contemporaries however have given different accounts of the college; and it is surely a very singular circumstance, that at this period of *idleness*, our author should have become enamoured of Sir John Marshall's *Canon Chronicon*, and have conceived the idea of writing an *Essay on the Age of Sesostris*. Such, however, was the case; and there is great reason to suppose Mr. Gibbon desirous of attributing to this negligent conduct of his tutors, his having at the age of sixteen bewildered himself in the errors of the church of Rome. On the 8th of June, 1753, at the feet of a priest in London, he solemnly, though privately, abjured the errors of heresy, and an elaborate controversial epistle, approved by his director, and addressed to his father, announced and justified the step he had taken. The old gentleman, however, in the first fury of passion having divulged the secret, the gates of Magdalen College were shut against the convert, and as it then was necessary therefore to form a new plan of education, our young Catholic was settled, on the 30th of June, under the roof of Mr. Paviliard, a Calvinist minister at Lausanne in Switzerland.

Under this amiable preceptor's tuition he describes his progress in the French and Latin classics, in history, geography, logic, and metaphysics, as uncommonly rapid; and he allows to the same man a handsome share of the honour of reclaiming him from the errors of popery. The various discriminating articles of the Romish creed disappeared like a dream;

and, after a full conviction, on Christmas-day 1754 he received the sacrament in the church of Laufanne. Thus had our author communicated with three different societies of Christians before the completion of his eighteenth year; and as such changes from church to church are always dangerous, we need not wonder that, in a mind so ill furnished as Mr. Gibbon's then was for theological investigations, they paved the way for his last change to Deism, of which he has since been the notorious advocate.

In 1757 Voltaire arrived at Laufanne, and our student's desire to see the man who was at once a poet, an historian, and, as he deemed himself, the prince of philosophers, was ardent, and easily gratified. He was received by the vain and arrogant Frenchman with civility as an English youth, but could not boast of any peculiar notice or distinction. "The highest gratification (says he) which I received from Voltaire's residence at Laufanne, was the uncommon circumstance of hearing a great poet declaim his own productions on the stage. His declamation was fashioned to the pomp and cadence of the old stage; and he expressed the enthusiasm of poetry rather than the feelings of Nature."

Mr. Gibbon now became enamoured of Mademoiselle Susan Curchod, the daughter of the minister of Crasly, in the mountains which separate the Pays de Vaud from the county of Burgundy. In terms of rapture he describes this lady as possessed of every accomplishment which could adorn her sex. She listened to the voice of truth and passion; her parents honourably encouraged the connection; and our author indulged in the dream of felicity: but on his return to England, he discovered that his father would not hear of this strange connection, and that without his consent he was destitute and helpless. "After a painful struggle (says he) I yielded to my fate. I sighed as a lover, I obeyed as a son; and my wound was infensibly healed by time, absence, and the habits of a new life." The lady consoled herself by giving her hand to the celebrated M. Neckar, then a rich banker of Paris, afterwards the minister, and at last one of the destroyers of the French monarchy.

In the spring of the year 1758 our author returned to London, where, having but few acquaintances, and hardly any friends, and being accustomed to a very small society at Laufanne, he was far from finding himself agreeably situated. This at length determined him once more to prefer the retirement of the country to the bustle of an over-grown metropolis, where he found hardly any entertainment but in the theatres.

Before he quitted Laufanne, however, he had begun a work on the study of ancient literature, which was suggested by the desire of justifying and praising the object of a favourite pursuit. "In France (says he), to which my ideas were confined, the learning and language of Greece and Rome were neglected by a philosophic age. The guardian of those studies, the Academy of Inscriptions, was degraded to the lowest rank among the three royal societies of Paris: the new appellation of *Erudits*, was contemptuously applied to the successors of Lippius and Casaubon; and I was provoked to hear, that the exercise of the memory, their sole merit, had been superseded by the nobler faculties of the imagination and the judgment. I was ambitious of proving by my own example, as well as by my precepts, that all the faculties of the mind may be exercised and displayed by the study of ancient literature." This laudable ambition continued; and in his father's house at Beiriton in Hampshire he finished his *Essai sur l'Etude de la Littérature*; which, after being revised by Mallet the poet and Dr. Maty of the British Museum, was, in 1761, published in a small 12mo. volume.

At the end of the war he again went abroad, and reached

Paris on the 28th of January, 1763, only 36 days after the disbanding of the militia in which he had borne the commission of a captain. In that metropolis he visited the palaces, churches, gardens, and theatres, was introduced to D'Alembert and Diderot, then considered as at the head of French science, and then proceeding to Switzerland, he once more took up his residence at his favourite Laufanne. Voltaire's impetuous had forced him from that town to his own castle at Ferney, where our author once visited him, without (he says) "courting his more intimate acquaintance."

The society in which Mr. Gibbon most delighted during his second residence at Laufanne was a very singular one. "It consisted of fifteen or twenty unmarried ladies of genteel families; the eldest perhaps about twenty, all agreeable, several handsome, and two or three of exquisite beauty. At each other's houses they assembled almost every day, without the control, or even the presence, of a mother or an aunt; they were trusted to their own prudence, among a crowd of young men of every nation in Europe. They laughed, they sung, they danced, they played at cards, they acted comedies; but in the midst of this carefree gaiety, they respected themselves, and were respected by the men; the invisible line between liberty and licentiousness was never transgressed by a gesture, a word, or a look, and their virgin chastity was never sullied by the breath of scandal or suspicion."

We readily agree with our author that this singular institution was expressive of the innocent simplicity of Swiss manners; and we only regret that he had not the same respect for the ladies of his own country as for those frolic females of Switzerland. He would not, in that case, have stained some of his most brilliant pages with obscene ribaldry.

We shall not follow him in his ramble through Italy, or repeat his remarks on the towns which he visited. It is sufficient to observe, that it was at Rome, on the 5th of October, 1764, while he sat musing amidst the ruins of the Capitol; that the idea of his great work first arose into his mind.

To that great work, The History of the Decline and Fall of the Roman Empire, he sat down seriously in 1768; and the history which he gives of his preparatory studies sufficiently accounts for the inaccuracy of his quotations. Through the darkness of the middle ages he explored his way in the annals and antiquities of Italy by the learned Muratori and other moderns; and seems to acknowledge that, from the beginning to the end of his work, he frequently contented himself with authorities furnished at second hand.

In 1776, the first volume of his history was published; and the success of it far surpassed his expectation. The encomiums lavished on it by Dr. Robertson and Mr. Hume in letters to the author, and the fulsome compliments which those three eminent historians paid to each other, are melancholy specimens of lettered littleness and vanity. The second and third volumes appeared in 1781; the fourth, fifth, and sixth in 1787; and Mr. Gibbon's fame was established as an historian. The work was admired both by natives and by foreigners, and translated into several of the languages of Europe. Dr. Zimmermann represents the author as excelling perhaps Hume and Robertson, who were historians of the first rank. "All the dignity (he adds), all the charms of historic style, are united in Gibbon: his periods are melody itself, and all his thoughts have nerve and vigour." This praise, however, must not be admitted without exception. Few writers, indeed, were possessed of such popular talents as our historian. The acuteness of his penetration, and the fertility of his genius, have been seldom equalled, and scarcely ever surpassed. He seizes, with singular felicity, on all the most interesting facts and situations, and these he embellishes with the utmost luxuriance of fancy and elegance of style. His periods are full

and harmonious; his language is always well chosen, and is frequently distinguished by a new and peculiarly happy adaptation. His epithets, too, are in general beautiful and happy; but he is rather too fond of them. The uniform statement of his diction sometimes imparts to his narrative a degree of obscurity, unless he defends to the miserable expedient of a note, to explain the minutest circumstances. His style, on the whole, is much too artificial; and this gives a degree of monotony to his periods, which extends, we had almost said, to the turn of his thoughts.

A more serious objection is his attack upon Christianity; the loose and disrespectful manner in which he mentions many points of morality regarded as important on the principles of natural religion; and the indecent allusions and expressions which too often occur in the work. An attack upon Christianity is not censurable merely as such; it may proceed from the purest and most virtuous motives: but, in that case, the attack will never be carried on in an insidious manner, and with improper weapons; and Christianity itself, so far from dreading, will invite every mode of fair and candid discussion. Our historian, it must be confessed, often makes, when he cannot readily find, an opportunity to insult the Christian religion. Such, indeed, is his eagerness in the cause, that he stoops to the most despicable pun, or to the most awkward perversion of language, for the pleasure of turning the Scripture into ribaldry, or calling Jesus an impostor.

Yet of the Christian religion has Mr. Gibbon himself observed, that it "contains a pure, benevolent, and universal system of ethics, adapted to every duty and every condition of life." Such an acknowledgment, and from such a writer too, ought to have due weight with a certain class of readers, and of authors likewise, and lead them seriously to consider, how far it is consistent with the character of good citizens, to endeavour, by fly insinuations, oblique hints, indecent sneer, and profane ridicule, to weaken the influence of *de pure and benevolent* a system as that of Christianity, acknowledged to be admirably calculated for promoting the happiness of individuals, and the welfare of society.

The part of the History which gave such offence to his own friend, as well as to the friends of the Christian religion in general, was the account which our historian has given of the progress and establishment of Christianity in the two last chapters of his first volume; in which he endeavours to prove that the wonderful triumph of that religion over all the established religions of the earth, was not owing to any miraculous attestations to its truth, but to five secondary causes which he enumerates; and that Christianity, of course, could not be of divine origin. Several answers appeared on this occasion, written, as we may naturally suppose, with different degrees of temper and ability. His principal opposers were Dr. Chelsum, Dr. Randolph, Dr. Watton (bishop of Llandaff), Lord Hailes, Dr. White, Mr. Aphorpe, Mr. Davis, and Mr. Taylor, author of *The Letters of Ben Mordecai*. One of them only, Mr. Davis, who had undertaken to point out various instances of misrepresentation, inaccuracy, and even plagiarism in his account, did our historian condescend particularly to answer, and that in a tone of proud contempt and confident superiority. To this Mr. Davis replied; and it is but justice to observe, that his reply bears evident marks of learning, judgment, and critical acumen, and that he has convicted our author of sometimes quoting inaccurately to serve a purpose. At his other answers Mr. Gibbon merely glanced, treating Dr. Watton, however, with particular respect; but his posthumous memoirs shew how much he felt the attacks made on him by Lord Hailes, Dr. White of Oxford, and Mr. Taylor. To Dr. Priestley, who, in his *History of the Corruptions of Christianity*, threw down his gauntlets at once to Bishop

Hurd and the historian of the Roman empire, and who presented the latter with a copy of his book, declaring, at the same time, that he sent it not as a gift but as a *challenge*, he wrote in such terms as produced a correspondence, which certainly added not to the honour of the dissenting divine.

At the beginning of the contest between Great Britain and America, our author was returned, by the interest of Mr. Eliot (now Lord Eliot), for the borough of Liskeard, and supported, with many a sincere and silent vote, the rights, though not, perhaps, the interest, of the mother country. "After a fleeting, illusive hope, prudence condemned me (says he) to acquiesce in the humble station of a mute. I was not armed by Nature and education with the intrepid energy of mind and voice. '*Vincemur strepitus, et natum rebus agendis*.' Timidity was fortified by pride; and even the success of my pen discouraged the trial of my voice."

That pen, however, was useful to the ministry whom he could not support by his eloquence in the house. At the request of the Lord Chancellor and Viscount Weymouth, then secretary of state, he vindicated, in a very able manner, against the French manifesto, the justice of the British arms; and his *Mémoire justificatif* was delivered as a state paper to the courts of Europe. He was rewarded for this service with the place of one of the lords commissioners of trade and plantations; and kept it, till the board was abolished by Mr. Burke's reform bill. For accepting this place he was severely, but most unjustly, blamed by some of the leaders of the opposition, as if he had deserted a party in which he had never enlisted, and to the principles of which he was rendered inimical both by family prepossession and by his own judgment.

On the downfall of Lord North's administration, Mr. Gibbon was of course in the opposition, deprived of an office, without the salary of which he could not conveniently support the expence of living in London. The coalition was indeed soon formed, and his friends were again in power; but having nothing to give him immediately, they could not detain him in parliament or even in England. He was tired of the bustle of the metropolis, and sighed once more for the retirement of Lausanne, at which he arrived before the overthrow of the coalition ministry, and where he lived happily till the last years of his life. It was in this retreat that he wrote the fourth, fifth, and sixth volumes of his history; and he left it only for a year, to superintend the publication of these volumes in London. This great work being concluded, he returned to the banks of the Leman lake, but found his enjoyments damped by the distress, and soon afterwards by the death, of his oldest and dearest Swiss friend. Lausanne had now lost much of its attraction; the French revolution had crowded it with unfortunate emigrants, who could not be cheerful themselves or excite the cheerfulness of others; and the demons of democracy had begun to poison the minds of the sober citizens with principles which Mr. Gibbon had always held in abhorrence. From the effects of this Gallic phreny, which began to be very visible so early as the beginning of the year 1792, Mr. Gibbon resolved to take shelter in England, and to abandon, for some time at least, what he called his paradise at Lausanne. Difficulties intervened, and forced him to postpone his journey from week to week, and from month to month; but on receiving the accounts of Lady Sheffield's death, he hastened to administer consolation to his friend, and arrived in London in the beginning of June 1793.

He continued well through the whole of that summer; but his constitution had suffered much from repeated attacks of the gout, and from symptoms of dropsy, under which he at last sunk, and died at his lodgings in St. James's street, London, on the 16th of January 1794.

To draw at once a general and just character of this extraor-

inary man, would be difficult perhaps to one who had enjoyed the pleasure of his acquaintance, and must be impossible to those to whom his person was a stranger. Of the extent of his erudition there can be but one opinion; but various opinions may be held respecting the accuracy of his knowledge. Lord Sheffield, who knew him well, and loved him much, assures us, that his conversation was still more captivating than his writings: but this could not result from the brilliancy of his wit; for of wit he declares, himself, that he had none. His memory was capacious and retentive, his penetration uncommon, and his colloquial eloquence ready and elegant; so that he could illustrate almost any topic of conversation from the copious stores of his own mind. From his private correspondence, and a journal not written for the public eye, he appears to have been a dutiful son, a loyal subject, and an affectionate and steady friend; but it is difficult to reconcile with so much moral and political worth his unfair and unmanly sneers at the religion of his country.

GIEN, a town of France, in the department of Loiret, seated on the Loire, 76 miles S.E. of Paris. Long. 2. 43. E. Lat. 47. 34. N.

GIENGEN, an imperial town of Suabia, 16 miles N.N.E. of Ulm, and 28 N.W. of Augsburg. Long. 10. 18. E. Lat. 48. 37. N.

GIENZOR, a town of Barbary, in Tripoli, 10 miles from the town of Tripoli.

GIERACE, an episcopal town of Naples, in Calabria Ulteriore, seated on a mountain, near the sea, 32 miles N.E. of Reggio. Long. 16. 40. E. Lat. 38. 13. N.

GIESEN, a town of Germany, in the landgrate of Hesse-Cassel, with a castle and a university. It belongs to the house of Darmstadt, and surrendered to the French in 1796, but was soon after taken by the Austrians. It is seated on the Lahn, 16 miles W.S.W. of Marburg. Long. 8. 41. E. Lat. 50. 30. N.

GIGA, a small island on the W. coast of Scotland, between the isle of Skye and the peninsula of Cantyre, in Argyleshire, in which county it is included. The inhabitants annually export a considerable quantity of grain.

GIGNAC, a town of France, in the department of Herault, situate on the Herault, 14 miles W. of Montpellier. Long. 3. 44. E. Lat. 43. 30. N.

GILCHRIST (Dr. Ebenezer), an eminent Scots physician, was born at Dumfries in 1707. He began the study of medicine at Edinburgh, which he afterwards prosecuted at London and Paris. He obtained the degree of doctor of medicine from the university of Rheims; and in the year 1732 he returned to the place of his nativity, where he afterwards constantly resided, and continued the practice of medicine till his death.

It may with justice be said, that few physicians of the present century have exercised their profession in a manner more respectable or successful than Dr. Gilchrist; and few have contributed more to the improvement of the healing art. Having engaged in business at an early period of life, his attention was wholly devoted to observation. Endowed by nature with a judgment acute and solid, with a genius active and inventive, he soon distinguished himself by departing, in various important particulars, from established but unsuccessful modes of practice. Several of the improvements which he introduced have procured him great and deserved reputation, both at home and abroad.

His practice, in ordinary cases, was allowed to be judicious, and placed him high in the confidence and esteem of the inhabitants of that part of the country where he lived. But his usefulness was not confined to his own neighbourhood. On many occasions he was consulted by letter from the most distant parts of the country.

VOL. X.

In different collections are to be found several of his performances, which prove that he had something new and useful to offer upon every subject to which he applied himself. But those writings which do him the greatest honour, are two long dissertations on nervous fevers, in the Medical Essays and Observations published by a Society in Edinburgh; and a treatise on the use of sea-voyages in medicine, which first made its appearance in the year 1757, and was afterwards reprinted in 1771. By means of the former, the attention of physicians was first turned to a species of fever which is now found to prevail universally in this country; and the liberal use of wine, which he was the first among the moderns to recommend, has since been adopted in these fevers by the most judicious physicians of the present age, and has probably contributed not a little to the success of their practice. His treatise on sea-voyages points out in a manner so clear, and so much on the sure footing of experience, their utility in various distempers, particularly in consumptions, that there is now a prospect of our being able to employ a remedy in this intractable disease much more efficacious than any hitherto in use. Dr. Gilchrist died in 1774.

GIMONT, a town of France, in the department of Gers, in the department of Gers, 12 miles E. of Auch. Long. 0. 48. E. Lat. 43. 37. N.

GIODDA, or **GIDDAN**, a sea-port of Arabia, on the Red Sea. It is the port of Mecca, and carries on a great trade. Long. 39. 27. E. Lat. 21. 30. N.

GIOVENAZZO, a town of Naples, in Terra di Bari, with a castle. It has high walls of rustic architecture, and high houses and towers, rising in narrow rows, built of polished stone with flat roofs, which give it a singular appearance. It is seated on a mountain, near the sea, 10 miles N.W. of Bari. Long. 16. 50. E. Lat. 41. 26. N.

GIREST, a large town of Persia, in Kerman. Its trade consists in wheat and dates. Long. 57. 55. E. Lat. 27. 30. N.

GIRGE, a town of Egypt, the capital of the Said, and residence of the bey of Upper Egypt, situate near the left bank of the Nile. It is about three miles in circumference; and is about 160 miles N. of Syene and 215 S. of Cairo. Long. 31. 22. E. Lat. 26. 30. N.

GIRVAN, a village in Ayrshire, at the mouth of a river of the same name, almost opposite the rock of Ailā. Here are some manufactures; particularly in the tanning of leather, and the making of shoes and boots. It is 16 miles S. by W. of Ayr.

GISBURN, a town in the W. riding of Yorkshire, with a market on Monday, 60 miles W. of York, and 210 N.W. of London. Long. 2. 22. W. Lat. 53. 55. N.

GISORS, a town of France, in the department of Eure. It belonged to the famous marshal Belleisle, whose only son, the count de Gisors, being killed at the battle of Grevelin, in 1758, the marshal, at his own death, in 1761, presented it to Lewis XV. It is seated on the Ept, 28 miles S.E. of Rouen. Long. 1. 43. E. Lat. 49. 15. N.

GITSCHIN, a town of Bohemia, which suffered greatly during the long war of the Swedes in Germany. It is 22 miles N.W. of Koniggratz, and 44 N.E. of Prague.

GIVET, a fortified town in the bishopric of Liege, divided in two by the river Maese, 21 miles S.W. of Namur. Long. 4. 34. E. Lat. 50. 13. N.

GIVIRA, a town of Italy, in the Milanese, seated on a lake of the same name, eight miles from Angbiera.

GLADBACH, a town of Westphalia, in the duchy of Juliers, 16 miles N. of Juliers. Long. 6. 10. E. Lat. 51. 14. N.

GLADENBACH, a town of Germany, in the principality of Upper Hesse, 12 miles N. of Gießen.

GLAMMIS, a village in the S.W. part of Angusshire.

Near it is Glammis castle, the ancient seat of the earl of Strathmore, in which is shewn the apartment where Malcolm II. was assassinated in 1034.

GLANFORDBRIDGE, or BAIGA, a town in Lincolnshire, with a market on Thursday; seated on the Ancholme, which is noted for fine eels, and has been lately made navigable for sloops to the Humber. It is 23 miles N. of Lincoln, and 156 N. by W. of London. Long. 0.23 . W. Lat. 53.35 . N.

GLASS-PAINTING. Having often been delighted with the grand effect produced by the windows of stained glass in old churches and monasteries, we have regretted that such fine and durable colouring should, in so many cases, have been prostituted upon wretched designs inferior to the productions of our sign-post daubers. We have wished that some mode could be devised of copying and multiplying pictures upon glass—some mechanical mode, which should require the aid of the artist in the first instance only, and leave all the subsequent operations to be performed by inferior hands, as in the case of copper-plate printing. Portraits at least, on a single piece of glass, which should perpetuate the features of great men and beautiful women, secure from that decay of colour and of canvas which has already begun to obliterate the finest paintings of the greatest artists whom the world has ever produced, might possibly be produced in the following way:

Suppose, after the outline of a likeness is drawn, that blocks were cut from it after the same manner as for calicoes, or paper-hangings, only with superior nicety, and in greater number for the purpose of multiplying and better blending the tints.

Enamellers must determine what shall be the proper substances for the different colours, and with what liquid they shall be moistened, that they may be readily taken up by the blocks, and thence transferred to another body by pressure.

From these blocks, and with these colours, let the figure be printed on paper; and, to prevent inaccuracy in bringing the separate parts, cut on the different blocks, to unite into a complete whole, let the paper be placed under a frame secured in an immovable position during the operation. The blocks being accurately squared, all exactly of the same dimensions, and each nicely fitting the frame, cannot, in passing through it to deliver their several impressions, make the smallest deviation from their intended places, but must produce an exact picture—at least on the paper.

To transfer that impression to glass, is, indeed, a work of nicety and difficulty. Were it not for some smaller strokes which must necessarily be in wood; the entire impression might in the outset be made on the glass itself, without any intervention of paper; since experience has proved to the callico-printers that the great masses of colour cannot be successfully delivered from wood; whereas they are obliged, in those parts of their patterns, to use bits of smooth worn-out beaver-hat, which might very well be pressed on the glass-plate.

However, from what we every day see effected in the case of prints affixed to glass without any of the paper remaining, and also of copper-plate embellishments upon porcelain and queen's ware, we doubt not that the picture, while fresh, may, by well-managed pressure, be transferred from the paper to an even plate of ground glass coated with a proper gluten which shall not, at least not materially, effusate its transparency; and experiment must determine whether the paper may afterward be gently drawn or peeled off, or must be burned away, or destroyed by a corrosive liquid, if any such can be found which will not injure the colours.

Suppose, however, the operation of removing the paper to

be satisfactorily performed, proceed we now to secure the delicacy of the picture.

Let a square plate of cast-iron, an inch or two in thickness, and as level and smooth as possible, be furnished on every side with a metal ledge rising an inch or more in height, which ought to be in two separate pieces, the one permanently fastened to the plate, the other capable of being removed at pleasure, for the purpose of laying in and taking out the glass without violence.

Within that ledge let the glass be fitted, closely touching it on every side, and lying with the painted surface uppermost. Upon this lay another plate of glass, fitted in the same manner.

Let, now, the metal frame, with the inclosed glasses, be exposed to the action of fire until the glass plates, without being melted to absolute fluidity, shall nevertheless become sufficiently soft to coalesce into one body under a strong pressure. The body which conveys the pressure, and lies in immediate contact with the glass, must equally fit and completely fill the entire space between the ledges, that there be no room for the soft glass to spread in any direction, so as to distort any of the lines of the picture.

Those who have witnessed the process pursued in softening tortoise-shell in the fire, and pressing it into the various shapes of snuff-boxes, *étuis*, &c. &c. will not conceive much difficulty in this use of the glass. It may be managed by the aid of a machine somewhat similar to, but more powerful than, a common printing-press, with a solid metal platine, to fit and fill the frame, as above; though much better contrivances may be found among the multifarious engines employed at Birmingham for the purposes of coining, and striking the heavy dies, than any we can possibly suggest.

In whatever manner the two glasses may be pressed into union, the united body may be afterward ground and polished and, in proportion to the greater smoothness of the two compressing bodies, the less grinding and polishing will be afterward required.

GLAUCHAU, a town of Upper Saxony, which has considerable manufactures of stufts. It is seated on the Muldaw, 46 miles W.S.W. of Dresden. Long. 12.35 . E. Lat. 50.45 . N.

GLAZING (*Encycl.*). The glazing of all our earthen ware is very apt to crack, both from moisture and heat, being composed of lead, one of the most pernicious metals that could be devised for such an important purpose. It is well known that lead is easily volatilized by heat, and readily decomposed by any vegetable acid: hence it has been affirmed by various eminent writers, that we are under the necessity of inhaling or swallowing, perhaps every day, a minute portion of a metal which is one of the slowest, but most destructive poisons, and lays the foundation of many fatal disorders, such as palsy, dry colic, consumption, &c. the remote cause of which has not, till lately, been suspected. In fact, there appears to be sufficient reason to believe, that our glazed culinary vessels are a latent source of disease; and when fruit or acids are allowed to remain in them for some time, the liquors or substances thus preserved will necessarily acquire a very dangerous impregnation from the metal. We therefore recommend various substitutes for lead to the attention of the public, both for this and other purposes.

M. Westrumb, an eminent German chemist, was required by the government of Hanover to devise a less pernicious method of glazing earthen ware than any hitherto practised. In consequence of numerous experiments, he has at length published the successful result of several compositions, in which not a particle of lead was employed, and which in

his opinion will prove an useful glazing for ordinary vessels. *First*: 32 parts of sand; 11, 15, or 20 parts of purified potash; and from 3 to 5 parts of borax. *Second*: 32 parts of glass (we suppose *flint-glass*); 16 parts of borax; and 3 parts of pure potash. *Third*: 150 parts of crystallized Glauber's-salt, with 8 parts of pulverized charcoal, previously roasted, till it has acquired a grey colour; 16 parts of sand; and 8 parts of borax.

Another method of *glazing without lead* has been invented by M. Niefleman, a potter at Leipzig: it consists of half a pound of saltpetre, half a pound of potash, and one pound of common salt. This composition is not very expensive, and said to produce an enamel not inferior to that prepared with lead. Professor Leonhardi has investigated, and found it eminently useful. We trust, therefore, our potters will in future, conscientiously desist from using that pernicious and slowly poisonous metal.

GLENARM, a small sea-port of Ireland, in the county of Antrim, with a castle; seated near a bay of its own name, 20 miles N.N.W. of Carrickfergus. Long. 6. 16. W. Lat. 55. 3. N.

GLENCOE, VALE OF, a valley, near the head of Loch Etive, in Argyshire; noted for a cruel massacre of its inhabitants in 1691. William III. having offered a general amnesty to the Highlanders who had been in arms for James II. provided they accepted it before the first of January, on pain of military execution after that period; the laird of Glencoe, on the last day of December, went to Fort William, the governor of which referred him to a civil officer. This made it the first of January before he could reach Inverary, where he surrendered to the sheriff, who, however, accepted his submission, in consideration of his offer to surrender the day before. The laird having taken the oaths, returned to Glencoe, in full assurance of safety; notwithstanding which, he, and his whole clan, were butchered, on the 15th of February, and all the houses in the valley were burnt.

GLENCROY, VALE OF, a wild and romantic tract, near the N.E. extremity of Loch Lomond, in Argyshire. The two ranges of mountains, which overhang this valley, approach each other, and between these the traveller is immersed. Their stupendous height, and the roaring of numerous cataracts, that pour over their broken surface, produce an awful effect.

GLENLUCE, a town in Wigtonshire, seated on the river Luze, near its entrance into the bay of that name, 16 miles W. by S. of Wigton.

GLENSHEE, SPITAL OF, a noted pass of the Grampian mountains, in Scotland, a little S. of the point where the counties of Perth, Angus, and Aberdeen meet. In 1718, a small body of Highlanders, with 300 Spaniards, took possession of this pass: but they retired at the approach of the king's forces, and were driven from one eminence to another till night, when the Highlanders dispersed; and, the next day, the Spaniards surrendered.

GLOMME, a river of the province of Aggerhuys, in S. Norway, which flows into the North Sea, at Fredericstادت. It receives the river Worme, which issues from Lake Mios. It is not navigable in any part of its course from this lake to Fredericstادت, its stream being intercepted by such frequent cataracts and shoals, as, in some places, to render it necessary to drag the trees, which are floated down, over the ground. At least 50,000 trees are annually floated by this river to Fredericstادت.

GLOUCESTER (*Encycl.*). See next article to **GLOBULE**. **GNESEN**. See **GENENA**.

GOAR, St. of GOWER, a town of Germany, in the circle of Lower Rhine, subject to the landgrave of Hesse Cassel.

It is seated under the stupendous rock and castle of Rheinfels, with which it surrendered to the French in 1794. It has a considerable commerce in wines and hides, and is 15 miles S.E. of Coblenz.

GOBCEIN, a town of Germany, in the palatinate of the Rhine, 18 miles S.E. of Philipburgh. Long. 8. 56. E. Lat. 49. 6. N.

GOCH, a town of Germany, in the duchy of Cleves, seated on the Neers, six miles S. of Cleves. Long. 5. 52. E. Lat. 51. 39. N.

GOCHSHEIM, or **GOCHSEN**, a town of Suabia, in the duchy of Wurtemberg, 16 miles S. of Heidelberg, and 24 N.N.W. of Stuttgart.

GOCIANO, a town of Sardinia, capital of a county of the same name, with a castle, seated on the Thurlo, 25 miles E. of Algher.

GODERVILLE, a town of France, in the department of Lower Seine, nine miles N.E. of Montivilliers.

GODRA, a town of Hindoostan Proper, in Guzerat, 55 miles E. of Amedabad. Long. 73. 40. E. Lat. 22. 50. N.

GOES, or **TER GOES**, a strong town of the United Provinces, in Zealand, and capital of the island of S. Beveland. It communicates with the Scheld by a canal, and is 20 miles E. of Middleburg. Long. 3. 50. E. Lat. 51. 33. N.

GOGMAGOG-HILLS, are hills so called, three miles from Cambridge, remarkable for the intrenchments and other works cast up here: whence some suppose it was a Roman camp; and others, that it was the work of the Danes.

GOGRA, or **SOORJEW RIVER**, a large river, which rises in Lake Lankee Dhe, in Thibet, and forcing its way through Mount Himmaleh, takes a S.E. direction, and unites with the Ganges, above Chuprah, in the province of Bahar.

GOHUD, a territory of Hindoostan Proper, in the province of Agra; subject to a rajah, who is tributary to the Poonah Maharrats. Gwalior is the capital.

GOLDBERG, a town of Silesia, in the duchy of Lignitz. It receives its name from a gold-mine near it, which was formerly very rich. The inhabitants are engaged in manufactures of woollen and linen. It is nine miles S.W. of Lignitz, and 36 W. of Breslaw. Long. 16. 23. E. Lat. 51. 3. N.

GOLD-FINCH, in ornithology. See **FRINGILLA**.

These are feed-birds of very curious colours, and which, were they not so common in this country, would probably be very much esteemed.

They are usually taken about Michaelmas, and soon become tame; but they differ very much in their song.—They frequently breed in the upper part of plum-trees, making their nests of the moss that grows upon apple-trees, and of wool; quilting the inside with all sorts of hairs they find upon the ground. They breed three times a-year; and the young are to be taken with the nest at about ten days old, and fed as follows:—Pound some hemp-seed very fine in a mortar; then sift it through a sieve, and add to it as much wheat-bread as hemp-seed; and likewise a little flower of canary-seeds: then with a small stick or quill, take up as much as the bigness of a white-pea, and give them several times a-day. This ought to be made fresh every day: for if it is suffered to sour, it will spoil their stomachs, causing them to cast up their meat; which if they do, it is very probable that they will die.—These young birds must be carefully kept warm till they can feed themselves, for they are very tender. In feeding, be sure to make your bird clean his bill and mouth. If any of the meat falls upon his feathers, take it off, or else he will not thrive. Such as eat hemp-seed, to purge them, should have the seeds of melons, succory, and mercury; or else let them have lettuce and plantane for that.

purpose. When there is no need of purging, give them two or three times a-week a little sugar or loam in their meat, or at the bottom of the cage; for all feels have an oiliness, so that if they have not something to absorb it, in length of time it fouls their stomachs, and brings on them a flux, which is very dangerous.

GOLDEN ISLAND, a barren island at the mouth of the river or gulf of Darien, where the Scots attempted to make a settlement in 1698. Long. 77. 10. W. Lat. 9. 0. N.

GOLDEN RULES, a distinguishing name for any precepts, worthy of universal observation. A better instance cannot be given than in "The twelve true old golden rules for those who like to fare better than they now do, and at the same time to thrive and grow rich," published during the late scarcity, by the Society for bettering the Condition of the Poor:

1. *The ready penny* always fetches the best bargain. He who buys upon trust, must not complain if he is cheated. The shopkeeper suspects his customer who *buys on trust*, and thinks that he means to cheat, and never to pay; and therefore he takes good care to be beforehand, and charges high accordingly.

2. The best pennyworth is to be had where most fit together, in the open market; and bargains are often cheaper in the latter end of the day.—When honest men have done their work, it is better for them to go to market, than to the alehouse.

3. When times are hard, why should we make them harder still? Is it not enough to be taxed once by government, without being taxed twice by folly, thrice by drunkenness, four times by laziness, and so on?—A good man, even in hard times, will do twice as well, as a bad man will in the best of times. Let us all then rise up *against ourselves*, who thus *tax and injure ourselves*: and we shall soon find that the times will mend. Let us *do good to ourselves at home*, and we shall become happy in our own habitations; and learn that it is a true saying, that "God helps those who help themselves."

4. *Time is our estate*; it is our most valuable property. If we lose it, or waste it, we can never—*never* purchase it back again. We ought, therefore, not to have an idle hour, or throw away an idle penny. While we employ our time and our property (however small that property may be) to the best advantage, we shall find that *a fortune may be made in any situation of life*; and that the poor man, who once wanted assistance himself, may become able to assist and relieve others.

5. *Industry* will make a man a purse, and *frugality* will find him strings for it. Neither the purse nor the strings will cost him any thing. He who has it, should only draw the strings as frugality directs; and he will be sure always to find a useful penny at the bottom of it. *The servants of industry* are known by their livery; it is always *whole and wholesome*. Idleness travels very leisurely, and poverty soon overtakes her. Look at the *ragged slaves of idleness*, and judge which is the best master to serve;—*Industry*, or *Idleness*.

6. *Marriage is honourable*: and the married state, when entered into with prudence, and continued in with discretion, is of all conditions of life the *most happy*; but to bring a wife home, before we have made provision for our industry and prudence, for her and our children, or to choose a wife, who has not, by attention and economy on her part, proved herself fit to manage a family, is *extremely imprudent and improvident*. Let, therefore, the young prepare themselves for the married state, by treasuring up *all the surplus of their youthful earnings*, and they will marry with confidence, and live together in comfort.

7. Of all *idolatry*, that ever debased any savage and ig-

norant nation, the worship of the *gin bottle* is the most disgraceful. The worshipper of the gin bottle becomes unfit for any thing; he soon rots his liver, and ruins himself and his family.

8. He who does not make his family comfortable, will himself never be happy at home; and he who is not happy at home, will never be happy any-where.—Charity begins at home: the husband and wife, who can hardly keep themselves and their children, should not keep a dog to rob the children of part of their food.

9. She who roasts or broils her meat, wastes half of it in the *fire*. She who boils it, loses half of it in the *water*. But when the good wife stews her meat gently, thickening the liquor with a little meal, ground rice, or pease and vegetables, and making it savoury with fried onions, herbs, and seasoning, her husband and the fare much better, their children thrive and grow hearty and stout, and their money goes twice as far.

10. When you stew or boil your meat, if you leave the vessel uncovered, a great deal of the best part goes off and is wasted in steam; and when you make the fire in a wide chimney, with a large open throat, there is at least twice as much of the heat goes up the chimney, as ever comes into the room to warm the family.

11. Sinning is a very expensive occupation.—Ask those who have practised it; they can tell you what it has cost them. The man who attempts to make you laugh at the fear of God is your worst enemy. In so doing, he endeavours to teach you to be *alto your own bitter and irreconcilable enemy for ever*, both in this world, and in the next.

12. Sin is the greatest of all evils; the salvation of the soul our best good; and the grace of God our richest treasure. Let the poor man find his way to the cheapest market on Saturday, to a place of divine worship on Sunday, and, like an honest man, go to his labour on Monday. Following these plain directions, he may be *twice happy*:—happy here, and happy hereafter to all eternity.

GOLEITA, an island of Africa, at the entrance of the bay of Tunis; taken by the emperor Charles V. when he attempted the siege of Tunis, and kept by the Christians several years. It is 29 miles N. of Tunis. Long. 10. 20. E. Lat. 37. 10. N.

GOLLING, a town of Germany, in the archbishopric of Saltzburg, 14 miles S.E. of Saltzburg.

GOLNAW, a town of Prussian Pomerania, seated on the lina, 18 miles N.E. of Stetin. Long. 14. 59. E. Lat. 53. 46. N.

GOMORRAH (anc. geog.), one of the cities of the plain or of the vale of Siddim in Judea, destroyed together with Sodom by fire from heaven, on account of the wickedness of the people. To determine its particular situation at present, is impossible.

GOMMERN, a town of Upper Saxony, situate on the Ehle, eight miles S.E. of Magdeburg, and 20 N.W. of Dessau. Long. 11. 50. E. Lat. 52. 5. N.

GOMS, a town of Switzerland, which gives name to one of the departments of the Valais. It is 33 miles E. of Sion.

GONAIVES, a sea-port of the island of St. Domingo, with an excellent harbour. Long. 72. 26. E. Lat. 19. 36. N.

GONAVE, an island in the W. Indies, near the W. coast of St. Domingo. Long. 73. 4. W. Lat. 18. 51. N.

GONDGAMA, or **GONDACOMMA**, a river of the peninsula of Hindoostan, which rises near Combam, forms the nominal boundary of the Carnatic on the N. and enters the bay of Bengal, at Mootapilly.

GONDRECOURT, a town of France, in the department

of Meuse, seated on the Orney, 20 miles S. of St. Michel. Long. 5. 37. E. Lat. 48. 30. N.

GONDREVILLE, a town of France, in the department of Meurthe, with a castle, and a magnificent hospital. It stands on a hill, on the river Moselle, eight miles from Nancy. Long. 6. 9. E. Lat. 48. 40. N.

GONSESSE, a town of France, in the department of Seine and Oise. It is the birth-place of King Philip Augustus, and noted for the goodness of its bread, which is brought twice a week to Paris. It is seated on the Crould, 10 miles N.E. of Paris. Long. 2. 30. E. Lat. 48. 58. N.

GONGA, an ancient town of Romania, seated near the sea of Marmora, 37 miles N.E. of Gallipoli. Long. 37. 31. E. Lat. 40. 53. N.

GONJAH, a kingdom of Africa, between the coast of Guinea on the S. and Tombuctou on the N. Gonjah, the capital, is 870 miles W. by S. of Cahna. Long. 6. 10. W. Lat. 13. 20. N.

GOORACPOUR, a town of Hindoostan Proper, in the country of Oude, 65 miles E. of Fyzabad. Long. 83. 35. E. Lat. 26. 45. N.

GORITZ, the capital of a county of the same name, in the duchy of Carniola, with a castle, seated on the Lifonzo, 16 miles N.E. of Aquileia. Long. 13. 30. E. Lat. 46. 20. N.

GORKAH, the capital of a country of the same name, in Asia, on the borders of Napaul, 35 miles N.W. of Catmandu, and 200 N. of Benares. Long. 84. 36. E. Lat. 28. 25. N.

GORZE, a town of France, in the department of Moselle. It had lately a rich abbey, and is seated on a hill, eight miles S.W. of Metz.

GOSSWEINSTEIN, or GOSSMANSTEIN, a town of Germany, in the circle of Franconia, and bishopric of Bamberg, 20 miles S.E. of Bamberg, and 23. N.N.E. of Nuremberg. Long. 11. 19. E. Lat. 49. 45. N.

GOSTYNEN, or GOSTAVIN, a town of Poland, in the palatinate of Rava, 36 miles N.E. of Rava. Long. 20. 40. E. Lat. 51. 54. N.

GOTTESBERG, a town of Silesia, in the duchy of Schweidnitz, remarkable for its silver mines. Near it is likewise a mine of gold, but it is not worked. It is 12 miles S.W. of Schweidnitz.

GOTTSCHEE, a town of Germany, in Carniola, 23 miles S.S.E. of Laybach, and 160 S.S.W. of Vienna. Long. 14. 43. E. Lat. 45. 53. N.

GOUDHURST, a town in Kent, with a market on Wednesday, 12 miles S.W. of Maidstone, and 44 S.E. of London. Long. 0. 31. E. Lat. 51. 8. N.

GOVERNULO, a town of Italy, in the Mantuan, seated on the Mincio, 12 miles S.E. of Mantua. Long. 10. 56. E. Lat. 45. 4. N.

GOURA, or GURA, a town of Poland, in the palatinate of Masovia, belonging to the bishop of Polesna. Long. 21. 50. E. Lat. 52. 1. N.

GOURAINCOURT, a town of France, in the department of Meuse, 15 miles N. E. of Verdun.

GOURDON, a town of France, in the department of Lot, 18 miles N.W. of Cahors. Long. 1. 24. E. Lat. 45. 43. N.

GOUROCK, a town in Renfrewshire, on a bay of the frith of Clyde. In its neighbourhood, a copper mine was lately worked.

GOWER, the peninsular extremity of Glamorganshire, to the W. of the bay of Swansea. It has very lofty lime-stone cliffs next the sea, whence large quantities of lime are exported to the English counties across the Bristol channel. The

coast abounds with oysters. The land is a fertile tract of arable and pasture.

GOWER, or GEVER. See GOAR, *St. Supp.*

GOZZI, or GOZES, an island of the Mediterranean, to the S. of the ile of Candia, 12 miles from fort Selino.

GOZZO, a fortified island of the Mediterranean, five miles N.W. of Malta, and belonging to the knights of that island.

GRABOW, a town of Lower Saxony, in the duchy of Mecklenburg, 18 miles S. of Schwerin. Long. 11. 44. E. Lat. 53. 26. N.

GRACCHUS (Tiberius), elected tribune of the Roman people, demanded in the senate, in their name, the execution of the Agrarian law; by which all persons possessing above 200 acres of land were to be deprived of the surplus, for the benefit of the poor citizens, amongst whom an equal distribution of them was to be made; having carried his plan into execution by violent measures, he fell a victim to his zeal, being assassinated by his own party, 133 B.C. Caius, his brother, pursuing the same steps, was killed by the consul Opimius, 121 B.C.

GRACIAS A DIOS, a town of Mexico, in the province of Honduras, 140 miles E. of Guatemala. Long. 72. 15. W. Lat. 14. 30. N.

GRACIOSA, one of the Azores, or Western Islands. Its inhabitants are about 300, and its produce is wheat, wine, butter, and cheese. Long. 27. 58. W. Lat. 39. 2. N.

GRACIOSA, a rocky, barren, uninhabited island, one of the Canaries, to the N. of Lacerota. It is three miles long, and two broad.

GRAFTON, a village in Northamptonshire, between Stony Stratford and Northampton, where there is a manor-house and park, given by Charles II. to the Duke of Grafton, whence the title is derived.

GRAHAM'S MURR, between the Carron Works and Falkirk, in Scotland, a field celebrated for being the spot where Sir William Wallace, in 1298, cut his way through the midst of his victorious enemies.

GRAMAT, a town of France, in the department of Lot, 22 miles N.N.E. of Cahors. Long. 1. 37. E. Lat. 44. 47. N.

GRAN, a town of Lower Hungary, with an archbishop's see. It has been several times taken and retaken, but lost of all by the Austrians, in 1683. It is seated on the Danube, 87 miles E. by S. of Vienna. Long. 18. 6. E. Lat. 47. 46. N.

GRANARY (*Encycl.*) In the 8th vol. of the "*Letters and Papers of the Bath and West of England Society*," &c. Thomas South, esq. gives a description of a cheap and efficacious ventilator, for preserving corn on ship-board. This machine consists of a forcing pump, with perforated tubes annexed to it; and by means of which fresh air may be communicated to every part of the cargo.—Mr. South's air-vessel is, for the sake of cheapness, confined to a diameter of 10 inches; but he observes that, if the latter be enlarged to 14 inches, the effect of the machine will be nearly doubled; and if the length of the trough (by the suction-valve) be extended 10 inches, a power will be obtained capable of ventilating a cargo of 400 tons in the course of one hour. The price of a ventilator on the smaller plan, is computed by Mr. South at about five or six guineas; one on a larger scale might perhaps amount to twenty guineas: a sum which, in either case, enhances the price of corn only at a rate of less than four pence per quarter, on the first cargo. These machines, if well painted and properly preserved, will continue useful for many years.—A more minute account of Mr. South's invention is

contained in the volume of the "*Letters*," &c. before quoted, where its various parts are specified and illustrated by an engraving.

To preserve corn in barns or granaries, Dr. Darwin observes, it is requisite first to make them dry, and, secondly, to keep them in that state; because no seeds will vegetate without moisture. In order to dry feeds, the heaps should be frequently turned over in warm dry weather: hence, in this climate, the doors and windows of granaries should open towards the south, for the reception of the warmth of the sun, with air-holes round the building, for sufficient ventilation; and which apertures ought to be sheltered from rain or snow, by boards placed for that purpose on the outside.—Heaps of corn should be surrounded with planks, in order to prevent them from touching either brick or stone walls; because, when cold north-east winds are succeeded by moist and warm south-west winds, such walls frequently precipitate the moisture from the atmosphere, and communicate it to those bodies which are in contact with them.—According to Mr. Tull, the safest method of preserving a large quantity of wheat is, to dry it gradually in a malt-kiln on a hair-cloth, with no other fuel than clean straw, and with a heat scarcely exceeding that produced by the rays of the sun.—In this temperature, the grain is to remain from 4 to 12 hours, in proportion to its previous dampness. The vegetative principle of the corn is not destroyed by this process; as instances have occurred of its growing when sown, after it had been thus kept for seven years.

GRANDEUR and SUBLIMITY. These terms have a double signification: they commonly signify the quality or circumstance in objects by which the emotions of grandeur and sublimity are produced; sometimes the emotions themselves.

In handling the present subject, it is necessary that the impression made on the mind by the magnitude of an object, abstracting from its other qualities, should be ascertained. And because abstraction is a mental operation of some difficulty, the safest method for judging is, to choose a plain object that is neither beautiful nor deformed, if such a one can be found. The plainest that occurs, is a huge mass of rubbish, the ruin perhaps of some extensive building; or a large heap of stones, such as are collected together for keeping in memory a battle or other remarkable event. Such an object, which in miniature would be perfectly indifferent, makes an impression by its magnitude, and appears agreeable. And supposing it so large, as to fill the eye, and to prevent the attention from wandering upon other objects, the impression it makes will be so much the deeper. See **ATTENTION**.

But though a plain object of that kind be agreeable, it is not termed *grand*: it is not entitled to that character, unless, together with its size, it be possessed of other qualities that contribute to beauty, such as regularity, proportion, order, or colour: and according to the number of such qualities combined with magnitude, it is more or less grand. Thus St. Peter's church at Rome, the great pyramid of Egypt, the Alps towering above the clouds, a great arm of the sea, and above all a clear and serene sky, are grand; because, beside their size, they are beautiful in an eminent degree. On the other hand, an overgrown whale, having a disagreeable appearance, is not grand. A large building agreeable by its regularity and proportions, is grand; and yet a much larger building destitute of regularity, has not the least tincture of grandeur. A single regiment in battle-array, makes a grand appearance; which the surrounding crowd does not, though perhaps ten for one in number. And a regiment where the men are all in one livery and the horses of one colour, makes

a grander appearance, and consequently strikes more terror, than where there is confusion of colour and dress. Thus greatness or magnitude is the circumstance that distinguishes grandeur from beauty: agreeableness is the genus, of which beauty and grandeur are species.

The emotion of grandeur, duly examined, will be found an additional proof of the foregoing doctrine. That this emotion is pleasant in a high degree, requires no other evidence but once to have seen a grand object: and if an emotion of grandeur be pleasant, its cause or object, as observed above, must infallibly be agreeable in proportion.

The qualities of grandeur and beauty are not more distinct, than the emotions are which these qualities produce in a spectator. All the various emotions of beauty have one common character, that of sweetness and gaiety. The emotion of grandeur has a different character: a large object that is agreeable, occupies the whole attention, and swells the heart into a vivid emotion, which, though extremely pleasant, is rather serious than gay. And this affords a good reason for distinguishing in language these different emotions. The emotions raised by colour, by regularity, by proportion, and by order, have such a resemblance to each other, as readily to come under one general term, viz. *the emotion of beauty*; but the emotion of grandeur is so different from these mentioned, as to merit a peculiar name.

Though regularity, proportion, order, and colour, contribute to grandeur as well as to beauty, yet these qualities are not by far so essential to the former as to the latter. To make out that proposition, some preliminaries are requisite. In the first place, the mind, not being totally occupied with a small object, can give its attention at the same time to every minute part; but in a great or extensive object, the mind, being totally occupied with the capital and striking parts, has no attention left for those that are little or indifferent. In the next place, two similar objects appear not similar when viewed at different distances: the similar parts of a very large object, cannot be seen but at different distances; and for that reason, its regularity, and the proportion of its parts, are in some measure lost to the eye; neither are the irregularities of a very large object so conspicuous as of one that is small. Hence it is, that a large object is not so agreeable by its regularity, as a small object; nor so disagreeable by its irregularities.

These considerations make it evident, that grandeur is satisfied with a less degree of regularity, and of the other qualities mentioned, than is requisite for beauty; which may be illustrated by the following experiment. Approaching to a small conical hill, we take an accurate survey of every part, and are sensible of the slightest deviation from regularity and proportion. Supposing the hill to be considerably enlarged, so as to make us less sensible of its regularity, it will upon that account appear less beautiful. It will not, however, appear less agreeable, because some slight emotion of grandeur comes in place of what is lost in beauty. And at last, when the hill is enlarged to a great mountain, the small degree of beauty that is left, is sunk in its grandeur. Hence it is, that a towering hill is delightful, if it have but the slightest resemblance of a cone; and a chain of mountains not less so, though deficient in the accuracy of order and proportion. We require a small surface to be smooth; but in an extensive plain, considerable inequalities are overlooked. In a word, regularity, proportion, order, and colour, contribute to grandeur as well as to beauty; but with a remarkable difference, that in passing from small to great, they are not required in the same degree of perfection. This remark serves to explain the extreme delight we have in viewing the face of nature, when sufficiently enriched and diversified with objects. The

bulk of the objects in a natural landscape are beautiful, and some of them grand: a flowing river, a spreading oak, a round hill, an extended plain, are delightful; and even a rugged rock, or barren heath, though in themselves disagreeable, contribute by contrast to the beauty of the whole; joining to these the verdure of the fields, the mixture of light and shade, and the sublime canopy spread over all; it will not appear wonderful, that so extensive a group of splendid objects should swell the heart to its utmost bounds, and raise the strongest emotion of grandeur. The spectator is conscious of an enthusiasm which cannot bear confinement, nor the strictness of regularity and order: he loves to range at large; and is so enchanted with magnificent objects, as to overlook slight beauties or deformities.

The same observation is applicable in some measure to works of art. In a small building, the slightest irregularity is disagreeable: but in a magnificent palace, or a large gothic church, irregularities are less regarded. In an epic poem, we pardon many negligences that would not be permitted in a sonnet or epigram. Notwithstanding such exceptions, it may be justly laid down for a rule, that in works of art, order and regularity ought to be governing principles; and hence the observation of Longinus, "In works of art we have regard to exact proportion: in those of nature, to grandeur and magnificence."

The same reflections are in a good measure applicable to *SUBILITY*: particularly, that, like grandeur, it is a species of agreeableness; that a beautiful object placed high, appearing more agreeable than formerly, produces in the spectator a new emotion, termed the *emotion of sublimity*; and that the perfection of order, regularity, and proportion, is less required in objects placed high, or at a distance, than at hand.

GRANICUS (*Encyel.*). Authors disagree very much about the number of the Persians engaged in this remarkable battle, though all agree that they were vastly more numerous than the Greeks. Justin and Orosius tell us, that the Persian army consisted of 600,000 foot and 20,000 horse; Arrian makes the foot amount to 200,000; but Diodorus tells us, that they were not more than 100,000 foot, and 10,000 horse. The Macedonian army did not exceed 30,000 foot, and 5000 horse. The Persian cavalry lined the banks of the Granicus, in order to oppose Alexander wherever he should attempt a passage; and the foot were posted behind the cavalry on an easy ascent. Parmenio would have had Alexander to allow his troops some time to refresh themselves; but he replied, that, after having crossed the Hellespont, it would be a disgrace to him and his troops to be stopped by a rivulet. Accordingly a proper place for crossing the river was no sooner found, than he commanded a strong detachment of horse to enter, he himself following with the right wing which he commanded in person; the trumpets in the mean time sounding, and loud shouts of joy being heard through the whole army. The Persians let fly such showers of arrows against the detachment of Macedonian horse, as caused some confusion; several of their horses being killed or wounded. As they drew near the bank a most bloody engagement ensued; the Macedonians attempting to land, and the Persians pushing them back into the river. Alexander, who observed the confusion they were in, took the command of them himself; and landing in spite of all opposition, obliged the Persian cavalry, after an obstinate resistance, to give ground. However, Spithroates, governor of Ionia, and son-in-law to Darius, still maintained his ground, and did all that lay in his power to bring them back to the charge. Alexander advanced full gallop to engage him; neither did he decline the combat, and both were slightly wounded at the first encounter. Spithro-

bates having thrown his javelin without effect, advanced sword in hand to meet his antagonist, who ran him through with his pike as he raised his arm to discharge a blow with his scymitar. But Rofaces, brother to Spithroates, at the same time gave Alexander such a furious blow on the head with his battle-ax, that he beat off his plume, and slightly wounded him through the helmet. As he was ready to repeat the blow, Clitus with one stroke of his scymitar cut off Rofaces's head, and thus in all probability saved the life of his sovereign. The Macedonians then, animated by the example of their king, attacked the Persians with new vigour, who soon after betook themselves to flight. Alexander did not pursue them; but immediately charged the enemy's foot with all his forces, who had now passed the river. The Persians, disheartened at the defeat of their cavalry, made no great resistance. The Greek mercenaries retired in good order to a neighbouring hill, whence they sent deputies to Alexander, desiring leave to march off unmolested. But he, instead of coming to a parley with them, rushed furiously into the middle of this small body; where his horse was killed under him, and he himself in great danger of being cut in pieces. The Greeks defended themselves with incredible valour for a long time, but were at last almost entirely cut off.—In this battle the Persians are said to have lost 20,000 foot, and 2,500 horse, and the Macedonians only 55 foot, and 60 horse.

GRANT (Francis), Lord Cullen, an eminent lawyer and judge in Scotland, was descended from a younger branch of the family of the Grants of Grant in that kingdom, and was born about the year 1660. When he commenced advocate he made a distinguished figure at the Revolution, by opposing the opinion of the old lawyers, who warmly argued on the inability of the convention of estates to make any disposition of the crown. The abilities he shewed in favour of the revolution recommended him to an extensive practice; in which he acquired so much honour, that when the union between the two kingdoms was in agitation, Queen Anne unexpectedly, and without application, created him a baronet, with a view of securing his interest in that measure; and upon the same principle, the soon after created him a judge, or one of the lords of session. From this time, according to the custom of Scotland, he was styled, from the name of his estate, Lord Cullen; and the same good qualities that recommended him to this honourable office, were very conspicuous in the discharge of it; which he continued for 20 years with the highest reputation, when a period was put to his life by an illness which lasted but three days. He expired without any agony on March 16th, 1726.

His character is drawn to great advantage in the *Biographia Britannica*; where it is observed, among other remarks to his honour, "that as an advocate he was indefatigable in the management of business; but at the same time that he spared no pains, he would use no craft. He had so high an idea of the dignity of his profession, that he held it equally criminal to neglect any honest means of coming at justice, or to make use of any arts to elude it."

"In respect to fortune, though he was modest and frugal, and had a large practice, yet he was far from being avaricious. His private charities were very considerable, and grew in the same proportion with his profits. He was, besides, very scrupulous in many points; he would not suffer a just cause to be lost through a client's want of money. He was such an enemy to oppression, that he never denied his assistance to such as laboured under it; and with respect to the clergy of all professions (in Scotland), his conscience obliged him to serve them without a fee. He saw their wrongs required assistance, and he knew their circumstances would not admit of expence. His additions, therefore, to his paternal estate were much infe-

rior to what might have been expected, and a large accession of character was the principal produce of that activity and diligence by which he was distinguished at the bar.

"When his merit had raised him to the bench, he thought himself accountable to God and man for his conduct in that high office; and that deep sense of his duty, at the same time that it kept him strictly to it, encouraged and supported him in the performance. The pleadings in Scotland are carried on chiefly in writing, which renders them sometimes very prolix, so as to take up much of the judge's time, and to exercise alike his parts and his patience in going through and making himself master of them. In this the diligence and dexterity of Lord Cullen were equally conspicuous: he went through every thing that came into his hands very carefully, and sifted it thoroughly; so that the lawyers at the bar never found themselves too strong for the bench, but on the contrary were often told many things by his lordship, which had either escaped their notice, or which the interest of their client had engaged them to conceal. As his attention to the pleadings guided him to the real merits of the cause; so when he was once master of these, his second care was to dispatch it. He knew, that, in judicature, the next fault to denying, was delaying justice; by which families are always injured, and too often ruined. Whenever, therefore, he had provided against being mistaken, he was desirous of bringing the matter to a short decision; and as he was very solicitous about the former, so the parties themselves helped him not a little as to the latter. Whenever he sat as lord ordinary; the paper of causes was remarkably full, for his reputation being equally established for knowledge and integrity, there were none, who had a good opinion of their own pretensions, but were desirous of bringing them before him, and not many who did not sit down satisfied with his decision. This prevailed more especially after it was found that few of his sentences were reversed; and when they were, it was commonly owing to himself: for if, upon mature reflection, or upon new reasons offered at the re-hearing, he saw any just ground for altering his judgment, he made no scruple of declaring it; being persuaded, that it was more manly, as well as more just, to follow truth, than to support opinion: and his conduct in this respect had a right effect; for instead of lessening, it raised his reputation.

"He would not, however, with all his great stock of knowledge, experience, and probity, trust himself in matters of blood, or venture to decide in criminal cases on the lives of his fellow-creatures; which was the reason that, though often solicited, he could never be prevailed upon to accept of a seat in the judiciary court.

"He was so true a lover of learning, and was so much addicted to his studies, that notwithstanding the multiplicity of his business while at the bar, and his great attention to his charge when a judge, he nevertheless found time to write various treatises, on very different and important subjects: some political, which were remarkably well-timed, and highly serviceable to the government: others of a most extensive nature, such as his essays on law, religion, and education, which were dedicated to his present Majesty when Prince of Wales; by whose command, his then secretary, Mr. Samuel Molyneux, wrote him a letter of thanks, in which were many gracious expressions, as well in relation to the piece, as to its author. He composed, besides these, many discourses on literary subjects, for the exercise of his own thoughts, and for the better discovery of truth; which went no further than his own closet, and from a principle of modesty were not communicated even to his most intimate friends.

"In his lordship's private character he was as amiable as he was respectable in his public. There were certain circum-

stances that determined him to part with an estate that was left him by his father; and it being foreseen that he would employ the produce of it, and the money he had acquired by his profession, in a new purchase, there were many decayed families who solicited him to take their lands upon his own terms, relying entirely on that equity, which they conceived to be the rule of his actions. It appeared that their opinion of him was perfectly well grounded. For being at length prevailed upon to lay out his money on the estate of an unfortunate family, who had a debt upon it of more than it was worth; he first put their affairs into order, and by calling the different demands, and compromising a variety of claims, secured some thousand pounds to the heirs, without prejudice to any, and of which they had never been possessed but from his interposition and vigilance in their behalf: so far was he either from making any advantage to himself of their necessities, or of his own skill in his profession; a circumstance justly mentioned to his honour, and which is an equal proof of his candor, generosity, and compassion. He was charitable without ostentation, disinterested in his friendships, and beneficent to all who had any thing to do with him. He was not only strictly just; but so free from any species of avarice, that his lady, who was a woman of great prudence and discretion, finding him more intent on the business committed to him by others, than on his own, took upon herself the care of placing out his money; and to prevent his postponing, as he was apt to do, such kind of affairs, when securities offered, she caused the circumstances of them to be stated in the form of cases, and so procured his opinion upon his own concerns, as if they had been those of a client. These little circumstances are mentioned as more expressive of his temper, than actions of another kind could be; because, in matters of importance, men either act from habit, or from motives that the world cannot penetrate; but, in things of a trivial nature, are left upon their guard, shew their true disposition, and stand confessed for what they are."

GRASMERE-WATER, a small lake of Westmoreland, to the W. of Ambleside. Its margin is hollowed into small bays, with bold eminences; some of rock, some of turf, that half conceal and vary the figure of the lake. From the shore, a low promontory projects far into the water; and on it stands a white village, with the parish church rising in the midst of it.

GRASON, an island in the gulf of Bothnia, near the coast of Sweden. Long. 18. 20. E. Lat. 60. 12. N.

GRASSANO, a town of Naples, in Basilicata, 18 miles E.S.E. of Cirenza.

GRASSE, a town of France, in the department of Var. It was lately a bishop's see; and is seated on an eminence, 15 miles W. of Nice. Long. 6. 56. E. Lat. 43. 39. N.

GRASSE, a town of France, in the department of Aude, seated on the river Othien, at the foot of the mountain of Courbiere, 18 miles S.E. of Carcassonne.

GRATELEY, a village in Hampshire, on the S.E. side of Quarley hill, in the road from Andover to Salisbury, where, in 926, King Athelstan held a grand council of the nobility. Near it is a great Roman camp, and on Quarley hill is a large British camp.

GRATES (*Encycl.*) Grates are peculiarly adapted to the use of pit-coal, which requires a greater draught of air to promote its burning freely, than any other kind of fuel. Most of them however are ill contrived for the purpose, and are especially injudicious, count Rumford observes, when made of, or connected to, large masses of iron, which being a rapid conductor of heat, sends off a large portion of what the fuel supplies, and which would otherwise be reflected into the room. No substance in nature, he says, has a stronger power

of reflecting heat than brick, a fact both understood and applied in the culture of wall-fruit: it is therefore of consequence to have as little iron as possible in our fire-places, and as much brick or fire-stone. See FIRE-PLACE.

Count Rumford's *cottage and gridiron* grates, are important contrivances to those who wish to derive a great deal of comfort from a small quantity of fuel. But for this end it is necessary to have the fire-place constructed with a scrupulous regard to his instructions, and to the models to be seen at the Royal Institution.

In the year 1791, a patent was granted to Mr. BENJAMIN CHARLES COLLINS, of Salisbury, Wilts, for a grate on a new construction, to be used either in or out of a chimney. This invention is said to be calculated to increase the action of the air upon fire, by augmenting and directing the passage of the former through the latter. Thus the fire may be rendered so intense as to present a perfect white heat; and, as the draught of air is very great, the patentee observes, that "all, or nearly all of the unignited smoke is carried down into the fire and then consumed, instead of passing off in the common way." To effect this purpose, he constructs one or more air-flues provided with stops, by which he may at pleasure promote the draught of air to the requisite degree of heat.

Grates of this construction are asserted to be very useful for light-houses, and other places requiring a strong fire, such as laboratories, brew-houses, smelting-furnaces, glass-houses, &c. — For a more circumstantial account of this patent, we must refer the reader to the 8th vol. of the *Repository of Arts and Manufactures*.

A later invention is that of Mr. BURNS's for fire-grates and fives.

The object of this supposed improvement is to prevent those disagreeable currents of air which gush from every opening and crevice in an apartment toward the fire-place, and also to impart greater equality to the temperature of the air in the different parts of the room. These objects he accomplishes by a contrivance similar to that used by many chemists for supplying their furnaces with fresh air. In lieu of our present fives or grates, he substitutes an urn-shaped stove standing in the chimney, having an opening in front to throw the fire, and supplied with air from without the house, where practicable, by means of a tube communicating with the fire, passing through the pedestal of the stove, and conducted through the hearth, in whatever manner is most convenient, to the outside of the house. Where the tube cannot be thus made to communicate with the external atmospheric air, it is conducted to a cellar or any other cool part of the house, whence the fire draws its requisite supplies of air, and at the same time creates a wholesome circulation in the air of that cellar or other room. The ashes fall into a metal drawer, where they remain concealed from view, and in which they are removed at once without raising any dust in the apartment.

Those who attempt to appreciate inventions of this kind, should examine well whether they are not (many of them) constructed on false principles; not perhaps as to the *production* but the *application* of heat.

GRAUDENTZ, a town of Poland, in the palatinate of Culm, with a castle; seated on the Vistula, 30 miles N. of Thorn, and 110 N.W. of Warsaw. Long. 18. 52. E. Lat. 53. 36. N.

GRAVEN MACHEREN, a town of Luxemburg, on the Moselle, 18 miles E.N.E. of Luxemburg. It was sacked and burnt, in 1552, by the Marquis of Brandenburg.

GRAVENWERT, a town of Lower Bavaria, 42 miles E.N.E. of Nuremberg.

GRAVESANDE, a town of Holland, where the ancient counts of Holland resided. It is seven miles W. of Delft.

GRAULHET, a town of France, in the department of Tarn, 12 miles N.W. of Castres.

GRAY'S THURROCK, a town in Essex, with a market on Thursday, seated on the Thames, 24 miles E. of London. Long. 0. 24. E. Lat. 51. 26. N.

GREBENSTEIN, a town of Germany, in the principality of Hesse Cassel, 12 miles N.W. of Cassel, and 16 N.N.E. of Naumburg. Long. 8. 58. E. Lat. 51. 16. N.

GREENLAW, the county-town of Berwickshire, seated on a river that joins the Tweed, before it reaches Berwick. It is 17 miles W. by S. of that town. Long. 2. 18. W. Lat. 53. 43. N.

GREENSBURGH, the county-town of Westmoreland, in Pennsylvania, 178 miles W. by N. of Philadelphia. Long. 78. 36. W. Lat. 40. 8. N.

GREENSTED, a village in Essex, one mile W. of Chipping Ongar, remarkable for its little church (built prior to the Conquest), the walls of which are formed of the trunks of trees placed in rows.

GRIEFFENHAGEN, a town of Upper Saxony, 37 miles N. of Custrin. Long. 15. 9. E. Lat. 53. 12. N.

GREIN, a town of the archduchy of Austria, situate on the Danube, 62 miles W. of Vienna. Long. 18. 5. E. Lat. 48. 16. N.

GREITZ, a town of Upper Saxony, in Voightland, with some stuff manufactures; situate on a small river, which runs into the Elster, 12 miles S.W. of Zwickau.

GRENADE (*Encycl.*). See GRANADA.

GREVENBROICH, a town of Westphalia, in the duchy of Juliers, 10 miles E.N.E. of Juliers. Long. 6. 18. E. Lat. 51. 6. N.

GREUSSEN, a town of Upper Saxony, in the county of Schweitzburg, 16 miles N. of Erfurt, and 18 E. of Muhlhausen. Long. 10. 45. E. Lat. 51. 6. N.

GRIESSEWALDE, a town of Upper Saxony, 24 miles S.E. of Stralund. Long. 11. 18. E. Lat. 54. 4. N.

GRIFFENHAKEN, a town of Prussian Pomerania, in the duchy of Stetin, seated on the Oder, opposite Gartz. Long. 14. 42. E. Lat. 53. 25. N.

GRIMBERGEN, a town of Austrian Brabant, with an abbey and a castle, six miles N. of Brussels. Long. 4. 27. E. Lat. 50. 57. N.

GRIMM, a town in the electorate of Saxony, with a citadel, seated on the Muldaw, 10 miles S.E. of Leipzig. Long. 12. 35. E. Lat. 51. 15. N.

GRIMMEN, a town of Swedish Pomerania, five miles S. of Stralund. Long. 13. 27. E. Lat. 54. 12. N.

GRIMPERG, a town in the electorate of Treves, with a bishop's see, 17 miles S.E. of Treves. Long. 6. 59. E. Lat. 49. 35. N.

GRIMSBY, GREAT (*Encycl.*). The market at this place is on Friday only.

GRINDELWALD, a town of Switzerland, in the canton of Bern, seated among mountains, at the foot of a celebrated Glacier, 25 miles S.E. of Thun. Long. 7. 43. E. Lat. 46. 27. N.

GROHNDE, a town of Lower Saxony, on the Weser. Near it is a monument of stone, erected in memory of a bloody battle fought there in 1421. It is nine miles S. of Hamelin.

GROLL, a town of Dutch Guelderland, in the county of Zutphen. It was often taken and retaken in the wars between the Dutch and Spaniards. The French took it in the year 1672, and demolished the fortifications. It is seated on the Slinghe, 15 miles S.E. of Zutphen.

GROSSA, an island of Dalmatia, in the gulf of Venice, near the coast of the county of Zara. It is 50 miles in circumference, and belongs to the Venetians.

GROSE (Francis), a distinguished antiquarian, born about the year 1731, was the son of Mr. Francis Grose of Richmond, jeweller, who filled up the coronation crown of George II. By his father he was left an independent fortune, which he was not of a disposition to add to, or even to preserve. Having once had a commission in the army, he entered into the Surrey militia, of which he became adjutant and paymaster; but to much had dissipation taken possession of him, that in a situation which above all others required attention, he was so careless as to have for some time (as he used pleasantly to tell) only two books of accounts, viz. his right and left hand pockets. In the one he received, and from the other paid; and this too with a want of circumspection which may be readily supposed from such a mode of book-keeping. His losses on this occasion roused his latent talents. With a good classical education he united a fine taste for drawing; and encouraged by his friends, as well as prompted by his situation, he undertook the work from which he derived both profit and reputation; we mean, his *Views of Antiquities in England and Wales*, which he first began to publish in numbers in the year 1773, and finished in the year 1776. The next year he added two more volumes to his *English Views*, in which he included the islands of Guernsey and Jersey, which were completed in 1787. This work answered his most sanguine expectations; and, from the time he began to the end of his life, he continued without intermission to publish various works (a list of which we subjoin), generally to the advantage of his literary reputation, and almost always to the benefit of his finances. His wit and good-humour were the abundant source of satisfaction to himself, and entertainment to his friends. He visited almost every part of the kingdom, and was well received wherever he went. In the summer of 1789 he set out on a tour in Scotland; the result of which he began to communicate to the public in 1790 in numbers. Before he had concluded this work, he proceeded to Ireland, intending to furnish that kingdom with views and descriptions of her antiquities, in the same manner as he had executed those of Great Britain; but soon after his arrival in Dublin, being at the house of Mr. Hone there, he died suddenly of an apoplectic fit, on the 6th of May, 1791, and was interred in Dublin. His natural tendency was to humour, in which he excelled both by the selection of anecdotes and his manner of telling them: it may be said, too, that his figure (extremely uncouth and bulky) rather assisted him, for it was in fact the very title page to a joke. He had neither the pride nor malignity of authorship: he felt the independency of his own talents, and was satisfied with them, without degrading others. His friendships were of the same cast; constant and sincere, overlooking some faults, and seeking out greater virtues. He had a good heart; and, abating those little indiscretions natural to most men, could do no wrong.

He married at Canterbury, and resided there some years, much beloved and respected for his wit and vivacity. He had two sons, Francis Grose, a major in the army, who, after several campaigns in America, was appointed in 1790 deputy governor of the new settlement at Botany Bay; and Onslow Grose, in the service of the East-India Company, lately deceased. Besides these he had two daughters both living.

His works are as follow: 1. *The Antiquities of England and Wales*, 8 vols. 4to. and 8vo. 2. *The Antiquities of Scotland*, 2 vols. 4to. and 8vo. 3. *The Antiquities of Ireland*, 2 vols. 4to. and 8vo. 4. *A Treatise on ancient Armour and Weapons*, 4to. 1785. 5. *A Classical Dictionary of the Vulgar Tongue*, 8vo. 1785. 6. *Military Antiquities*; being

History of the English Army from the Conquest to the present time, 2 vols. 4to. 1788. 7. *The History of Dover Castle*, by the Rev. Wm. Danell, 4to. 1785. 8. *A Provincial Glossary,*

with a Collection of local Proverbs and popular Superstitions, 8vo. 1788. 9. *Rules for drawing Caricatures*, 8vo. 1789, 10. *Supplement to the Treatise on Ancient Armour and Weapons*, 4to. 1789. 11. *A Guide to Health, Beauty, Honour, and Riches*; being a Collection of humorous Advertisements, pointing out the Means to obtain those Blessings; with a suitable introductory Preface, 8vo. 12. *The Olio*; being a Collection of Essays in 8vo. 1793.

GROSETTO, a town of Tuscany, with a castle and a bishop's see; situate near the sea, 30 miles S.W. of Sienna. Long. 11. 1. E. Lat. 42. 40. N.

GROYNE, a river of Spain, in Galicia, which enters the bay of Biscay, at Corunna.

GRUCKFELDT, a town of Carinthia, with a castle, on the river Save. Long. 15. 45. E. Lat. 46. 7. N.

GRUNBERG, a town of Germany in the principality of Upper Hesse, where the kings of the Merovingian race and Charlemagne held their court. It is 10 miles E. of Gießen, and 28 W. of Fulda.

GRUNBERG, a town of Silesia, in the principality of Glogau, surrounded with vineyards. Here is a manufacture of cloth. It is 12 miles N. of Freystadt, and 24 N.W. of Glogau.

GRUNDE, a town of Germany, in the duchy of Brunswick, and in the mountains of Hartz. Long. 13. 35. E. Lat. 52. 10. N.

GRUNHAYN, a town of Upper Saxony, in the circle of Erzgebirg, 46 miles W.S.W. of Dresden. Long. 12. 46. E. Lat. 50. 32. N.

GRUNINGEN, a town of Lower Saxony, in the principality of Halberstadt, on the river Elbe. Long. 11. 41. E. Lat. 52. 4. N.

GRUNSTADT, a town of Germany, in the circle of Upper Rhine, and county of Leiningen, 22 miles N.N.W. of Spire, and 28 S. of Mentz. Long. 7. 58. E. Lat. 49. 32. N.

GUACOCKINGO, a town of New Spain, 30 miles S.E. of Mexico. Long. 99. 45. W. Lat. 19. 36. N.

GUADARAMA, a town of Spain, in Old Castile, remarkable for its great trade in cheese. It is seated on the Guadarama, 25 miles N.W. of Madrid. Long. 3. 48. W. Lat. 41. 45. N.

GUADRAMIRO, a town of Spain, in Leon, 33 miles W.S.W. of Salamanca.

GUARDAMAR, a sea-port of Spain, in Valentia, at the mouth of the Segura. The chief trade consists in the exportation of salt. It is 17 miles S.S.W. of Alicante. Long. 6. 18. W. Lat. 38. 7. N.

GUARMA, a sea-port of Peru, 120 miles N.W. of Lima. Long. 77. 49. W. Lat. 10. 10. S.

GUASTO, or VASTO, a town of Naples, in Abruzzo Citeriore, on the Gulf of Venice, 15 miles S.E. of Lanciano, Long. 15. 6. E. Lat. 42. 15. N.

GUAYAQUIL, a sea-port of Peru, in the audience of Quito, and the capital of a jurisdiction of the same name. It is defended by three strong forts, and situate on the river Guayaquil, at its entrance into the gulf of Guayaquil, 140 miles N.N.E. of Paita, and 150 S.S.W. of Quito. Long. 78. 36. W. Lat. 2. 12. S.

GUERCHE, a town of France, in the department of Ille and Vilaine. 20 miles E.S.E. of Rennes. Long. 1. 20. W. Lat. 47. 57. N.

GUERGELA, a town of Barbary, in Biledulgerid, 80 miles S. of Mount Atlas. Long. 4. 50. E. Lat. 31. 45. N.

GUERNSEY (*Encycl.*). Of this island, Dr. Campbell gives the following account: "It lies 20 leagues south-west from Weymouth in Dorsetshire, between eight and nine leagues west from the coast of Normandy, 13 south of Bre-

tagne, seven north-west from Jerfey, five south-west of Alderney, and two west from Sark. In length from north-east to south-west, about twelve miles; in breadth, from south to north, about nine; in circumference, upwards of 30; containing 50 square miles, or 32,000 acres. The climate is mild and temperate; not subject to excessive heats, much less to severe cold; somewhat windy; but, taking all things together, equally healthy and pleasant. The soil is, generally speaking, rich and fertile; the country, though sufficiently enclosed with stone fences, yet more open than in Jerfey, and as capable of cultivation of every kind. On the north side, the coast is commonly low and flat, rising gradually, so that on the south side the cliffs are of a prodigious height. The face of the country is variegated with hills and little eminences, and tolerably well watered with springs and sharp gravelly streams. There was formerly a fine lake, about half a league in extent, now filled up, and turned into a meadow; but many gentlemen have still very beautiful and convenient fish-ponds.

"There are very few countries in the world more capable of improvement. Most of the rising grounds afford a short thick grass, equally beautiful to the eye, and succulent as pasture. Roots and herbs it produces of all kinds, excellent, medicinal, and aromatic; with a profusion of flowers that grow wild, and are exquisitely fragrant. All sort of shrubs and fruit-trees flourish here: and there is some, though but little, timber; not through any defect of soil or climate, but because they cannot conveniently afford it room. Grain they have of every species we cultivate in Britain, but more especially wheat; and though they have not either lime, chalk, or marle, yet the sea-wreck answers all the intention of manure, so well as to keep their ground in constant heart. They have large quantities of sheep, but small in size; and had formerly a very singular breed, of which the ewes had four horns, and the rams six; but these are now become very scarce. Their black cattle are in such abundance, as not only to support their own uses, but to furnish also a considerable exportation; and their horses, though but little, are equally strong and hardy. The sea also furnishes a prodigious variety as well as plenty of fish, more especially red and grey mullet, excellent mackerel, and above all, conger-eels. To these advantages we may add, the singular privilege of being free from all venomous creatures.

"There are in this island ten parishes, each of which is divided into several vintons, for the more easy management of affairs, civil, ecclesiastical, and military, and the choice of their respective officers and magistrates. Though the country is very fully peopled, yet the houses are scattered up and down, according to the humour or the convenience of the inhabitants: so that there is, properly speaking, but one town in the island, which is likewise the only haven of any resort; though there are some creeks on the north and west sides of the island, such as Bazon, L'Aucresse, Ferminier, St. Sampson, and the West Passage. All these ports are in a state of nature; but might be certainly improved and fortified, which would be productive of many advantages to the island; as was long ago observed and proposed to government by Captain Yarranton. In the reign of King Charles II. when the French formed an insidious design of making themselves masters of this island by treachery, it left such an impression on his majesty's mind, that some years after he sent over the Lord Dartmouth, accompanied by certain engineers, who discovered on the north-west side of the isle, a deep bay, which, by the help of a mole, might cover a numerous squadron, even of ships of the line, under the protection of what was also intended to be built, a strong castle: but his exchequer being exhausted, this necessary work was never carried into execution. As this port would look full into the channel,

it deserves consideration, how far it might be useful to us in the time of a French war, and of what infinite detriment it might prove if this island should ever fall into the hands of our enemies.

"The inhabitants are very industrious in their respective employments; naturally sober, frugal in their manner of living, honest in their dealings, sincere in their religion, which is that of the church of England, and loyal to their princes, as well as steady to the British interest. They are, however, reserved to a degree, that makes them sometimes thought morose; they are somewhat suspicious; and, which is their greatest error, they are, or at least were, very litigious. They are good husbandmen in their own way, and manage the sea-wreck (which first serves the poor people for fuel), and then its ashes are employed by those in better circumstances (for manure) with great skill, and under very prudent regulations. The wreck is cut in summer, and about the vernal equinox, by the proclamation of the magistrates, and when dried, distributed by their order. As for the winter-wreck, which after storms is thrown in large quantities on the coast; this is also equitably divided, and being firewood wet, and so ploughed into the ground, renders it continually fertile. They have a stronger turn, however, to grazing, than to agriculture; and though they bring in annually some corn, yet in the same space they feed out a few hundred cattle. They are still more inclined to orchards, which enables them to make many thousand hogheads of cyder every year; of which, it being the common drink of the people, they export but little. The woollen is their principal manufacture, for the carrying on of which they are allowed to import 2000 tons from England, which they work up chiefly in stockings, waistcoats, and breeches. They might certainly make their fishery turn to profit, more especially as of late years they have set up salt works; and yet, except lobsters, I never heard that any of their fish went to a foreign market. Our French and Portugal merchants have large stocks of wine here, which they import as they have occasion. As they are enabled, by this method, to keep it to a proper age before they are obliged to pay the duty, it seems to be a benefit to the mother-country, by putting it in their power both to buy and sell cheaper: as on the other hand, from the rent of warehouses, the subsisting factors and their servants, the resort of ships employed in this trade, it must be very advantageous to the inhabitants of this island. It is a point of justice to observe, that this manner of depositing wines, has nothing at all to do with smuggling; a practice equally injurious to the interests of this country and to the people of Guernsey, as it breeds few seamen, is carried on in very small vessels, and upon the whole is not only an infamous, but a very unprofitable kind of traffic. Heretofore, merchants of this isle traded to most parts of Europe, and had several stout ships of their own; and if this vile practice was abolished, as it might easily be, without any violation of the liberties of the people, they would soon find their account in it, by the revival of many lucrative branches of commerce. As they take away from England some of the necessaries, and almost all the conveniences, of life, such as corn, malt-liquor, sugars, spices, coals, household-furniture, many species of the iron and leather manufactures, grocery, haberdashery, and hard-wares, the balance is greatly in our favour; and must continually increase, in proportion as they augment in number, and grow easier in circumstances. At present, upon a very moderate computation, there are in Guernsey upwards of 15,000 souls.

"The several islets and vast chains of rocks that surround this country on every side, and cause such a variety of tides and currents, add much to the security of the place, by ren-

dering it equally difficult and dangerous for ships to approach it, unless they have pilots aboard extremely well acquainted with the coast. On the fourth side, the cliffs are prodigiously high; so that the old writers say, it looks like a park in the sea, impaled with rocks. On the west side lie the Hanoyas, or, as the French write them, *Hanocaua*, which cover that coast so effectually, that a descent there is little to be feared. At the north-west extremity lies a little island called *the Houe*; which would be a very convenient place for a salt-work, glass-house, or manufactory of soap. At the north-east extremity we meet with St. Michael in the Vale, a peninsula some miles in extent, connected with Guernsey by a very narrow isthmus, with bays that might be rendered useful on both sides. This peninsula is likewise guarded by rocks and islets, the most considerable of which are the Bryants, the Hummet, and the Hays. South-east from the vale, lies the island of Harnet, or Arne, about a league in compass, formerly desert, but now cultivated. At a league south from thence lies Briboe, of less extent; and between both, the little island of Gythau, or Jethau, which serves the governor for a kind of park, or rather paddock.

GUETA, a town of Spain, in New Castile, 60 miles E. of Madrid. Long. 1. 56. W. Lat. 40. 22. N.

GUGLINGEN, a town of Suabia, in the duchy of Wirtemberg, situate on the Zaber, 18 miles N. of Stuttgart, and 22 S.S.E. of Heidelberg. Long. 8. 56. E. Lat. 49. 2. N.

GULLAIN, St. a town of Austrian Hainault, seated in marshy land, on the river Haine, six miles W. of Mons. Long. 3. 53. E. Lat. 50. 27. N.

GUILLESTREE, a town and castle in the Alps, once belonging to Dauphiny, in France. It was taken by Prince Eugene in 1692, and is nine miles N.E. of Embrun. Long. 6. 36. E. Lat. 44. 41. N.

GUIMALAENS, an ancient town of Portugal, in the province of Entre-Douero-e-Minho. It has formerly been the residence of their kings, and is divided into the Old and New. The public buildings are magnificent, and the collegiate church is said to be founded on the ruins of a temple of Ceres. It is 10 miles S.E. of Braga. Long. 8. 21. W. Lat. 41. 35. N.

GUM (*Encycl.*). The following account of a discovery made by Citizen Leroux, of a gummy substance contained in the bulbous root of the *Hyacinthus non-scriptus*, is given by Citizen Deyeux, in the *Annales de Chimie*.

"It had long since been observed," says Citizen Leroux, "that the bulbous roots of some plants contained a mucilaginous substance; but no one had yet attempted to extract it, and still less to analyze it. A particular circumstance having given me occasion to employ the bulbs of the *Hyacinthus non-scriptus*, I was so much surprised at the great degree of viscosity which I found them to possess, that I did not suffer the favourable opportunity to escape me, which presented itself, for subjecting these roots to various experiments. It would be superfluous here to give an account of all the different trials which I have made: it will be sufficient for the present to inform you, that, having reduced 50 kilogrammes of the above-mentioned bulbs into a paste, by pounding them in a mortar, I diluted this paste with a sufficient quantity of water: the liquor, having been strained through a fine piece of linen, was afterwards evaporated to the consistence of a thick syrup. In this state it was poured into moulds of tinned iron, which were immediately placed in a stove.

The desiccation took place pretty rapidly; and when it was completed I found, at the bottom of each mould, a brittle transparent substance, which exhibited all the external characters of a real gum.

The 50 kilogrammes of the bulbs, which I employed, yielded me 8 kilogrammes of this gummy product. On comparing this product with various kinds of gums, it possesses the same properties; for, 1. treated with nitric acid, it yielded a twelfth of its weight of oxalic acid.

2. Dissolved in water, it rendered this fluid very (tinctu- cent).

3. This solution, left to itself in a rather warm temperature, soon grew four and mouldy.

4. Mixed with alcohol, it became turbid, and deposited a white flaky matter.

5. By distilling the dried gummy matter in a retort, the following products were obtained: phlegm, a very small quantity of oil, and the pyro-mucous acid. All these fluids had the smell of burnt bread, &c.

It is probable that this matter, as it exists in this root, is perfectly colourless; on cutting several pretty large bulbs transversely, the fluid, which flowed out spontaneously, dried upon the surface that had been laid bare, and formed a very transparent, and entirely colourless, pellicle.

The quantity of gum that may be extracted from these roots is sufficiently considerable to render its extraction an object worthy of attention. On calculating the expense with which it would be attended, it already appears, that if the extraction were carried on upon a large scale, it would not only repay the costs, but one might also hope to obtain some profit from it.

Citizen Leroux, after having prosecuted these experiments, imagined that he had succeeded, by a very simple process, in converting the above-mentioned gum into a substance analogous to the amylineous matter.

A patent was obtained in June, 1788, by Mr. Francis Blaikie, of Glasgow, merchant, for the invention (discovered to him) of a substitute for gum, in thickening colours for printing, which fully answers the purpose, and at a more reasonable rate.—This article is prepared by boiling flax-seed in water, till the whole substance is completely extracted; the liquor is next to be strained through a linen or woollen cloth, and boiled down to the consistence of a jelly. It is then to be put into a close vessel, and a small quantity of spirits, or sweet oil, poured on the top, in order to preserve it in a fresh state. In using this substitute, the printer is directed to put a certain portion into a gallon of colour, according to the nature of the latter, and the particular kind of work; while he should regulate himself by trial, in the same manner as is practised in employing common gum.

GUM (*Gumma*), in medicine, is a tumour arising out of the substance of a bone; it is so soft as to yield to the finger. When these tumours are harder they are called *tophi*; when harder still, they receive the name of *nodes*: but the hardest tumours in bones are *exostoses*. In venereal patients such tumours often happen on the head, and even in the middle of the most solid bones. They seem to be produced when the vessels running between the bony laminae, being either obstructed or inflamed, are dilated, and so raise the incumbent laminae. Perhaps the bone degenerates too into a morbid softness. A softness of the bones sometimes succeeds abscesses of the adjacent parts; and sometimes the origin of the disorder is lodged in the substance of the bone, especially in the lues venerea; gummata have, however, been discovered, when no such adequate cause could be observed. See SURGERY.

GUN (*Encycl.*) The following is the specification of a patent granted to Mr. Proffer, of Charing Cross, sword-cutter, for a water-proof pan and hammer for gun and pistol locks, and also a breech for gun and pistol barrels, for the purpose of a quicker and more forcible explosion of gunpowder. It

is dated Dec. 9, 1800, and the proprietor thus describes and ascertains the nature of his invention, and in what manner it is to be performed. A, in plate 32, is the hammer, perforated with a large hole, a little conical, to receive the cylinder B, round which A moves forward and backward. The end, No. 1, of the hammer A, in the inner side, has a circular groove, to receive the ward No. 2, which is on the screwed end of the cylinder B. This ward is for the purpose of preventing the admission of any water (which may fall between the hammer and the barrel of the gun or pistol) into the joint. The heel, No. 2; when the cock strikes the hammer A, falls upon the hammer spring, and prevents the hammer A going further round on the cylinder B than is necessary to expose the pan on the cylinder B. At the bottom of the face of the hammer A is a hole, made exactly the shape and size of the pan in the cylinder B; which hole, when the hammer A is turned round to its extent, admits the fire to fall into the pan on the cylinder B. Inside of the end, No. 3, of the hammer A, is a female screw, to receive the male screw C into it, which, when screwed into the end No. 3 of A, completely encloses the end of the cylinder B, so as to prevent the admission of water. B, is the cylinder, round which the hammer A acts, and which cylinder may be made of iron, steel, or metal, and is made a little conical. In this cylinder the pan and touch-hole are made; at the end of which is a male screw, No. 1, of a smaller diameter than the cylinder. This screwed end, No. 1, passes through the whole of the end No. 1 of the hammer A, and screws into the female screw of the hole No. 1 of the breech D. This screw goes quite into the chamber of the breech D, and a large conical hole is made in it, quite up to the touch-hole in the pan. This hole is made so large as to admit with ease the powder that falls into the chamber into it, and brings the bottom of the charge of powder quite close to the prime in the pan. The shoulder or ward No. 2, on the end of the cylinder B, when the cylinder B is in the hammer A, works in the circular groove, which is in the inner side of the end No. 1 of the hammer A, for the purpose before described. One side of the cylinder B is filed away to the same shape as the hole in the face of the hammer A, so as to give no impediment to the falling water of the face of the hammer A, when it is turned round over the pan. The hammer A is prevented falling too near the cock by having a knob of iron on the false breech of the barrel. The toe, No. 4, of the hammer A, works upon the usual kind of hammer springs, and might be used either with a roller or swivel spring. The breech D is made of two parts, and are screwed into each other, there being a male and female screw, each half being concaved into nearly equal parts, so as to form an oval chamber; at the bottom of which the touch-hole is placed, and at the top the chamber is contracted, so as to prevent the ramrod entering into the chamber; by which means the powder is left all loose, and free from pressure, and consequently will more forcibly, and with greater quickness, explode on the side of the breech D. A small screw, No. 2, is made to screw into the screwed end of the cylinder B, to prevent its turning round with the hammer A when it is operating. The above water-proof hammer and pan can be applied to any gun or pistol already made, either separate from, or in conjunction with, the breech D. The section E is a true representation of the form of the chamber in the breech D, when both parts are screwed together; and of the cylinder B, when screwed into the hole No. 1 of breech D."

GUNDELSINGEN, a town of Bavaria, in the duchy of Neuburg, situate on the Brenz, near the Danube, 19 miles N.E. of Ulm. Long. 10. 12. E. Lat. 48. 34. N.

GUNPOWDER (*Encycl.*) Some writers having lately attributed the invention of gunpowder to the Indians, and

Vol. X.

asserted that they employed it in their wars against Alexander, the writer of the following remarks was induced to examine the subject with some attention: he found the best account of gunpowder, as known to the Asiatics in early ages, given by the learned *Casiri*, in his *Biblioth. Hispan.-Arabica*, or Catalogue of the Oriental Manuscripts deposited in the Library of the *Escorial* in Spain (vol. II. p. 6). He there digresses into a curious little essay entitled, "*De Tormentorum bellicorum et nitrati pulveris apud Arabas antiquitate et usu*:" from which we have extracted and translated the following passages:

It is sufficiently known to those who have made ancient tactics the subject of their study, that the Greeks and Romans used missile fires, such as torches or flambeaux, burning arrows, and other instruments of fiery destruction, which they either cast by means of certain engines and machines, or flung with the hand into the places besieged.

Vegilius, in his book *De re militari*, and *Leo*, in his *Tactica*, treat very fully of these matters. The former, among his precepts to those who study the art of war, has the following passage: "If there should be houses in the fortrefs, or place besieged, of such materials as may be easily kindled, you may burn them by means of fiery arrows directed various ways, especially if the wind blow violently. You may also use squared stones full of fire and *manganica alacotia*, which project stones," &c. But among the Greeks and Romans we do not find any mention of *pulvis nitratus*, or gunpowder; and the time of its invention is not exactly ascertained by the antiquaries. *Charles Du Fresnoie*, in his *Glossar. Med. et inf. Latinit.* (in the word *Bombarda*), informs us, that "the inventor of gunpowder is said to have been a certain chemist, a monk, named *Berthold Schwartz*, or *Black*; and, according to the calculation of *Bartholomew du Drach*, it was used in France since the year 1338. But the invention has been ascribed to many others more modern than *Schwartz*."

The records, however, of the Arabians, trace the use of gunpowder to ages of far greater antiquity, among the Persians and the Africans. Whence it is very probable that the knowledge and use of it passed from the Arabians to the Spaniards, and from the Spaniards to the French, who, in process of time, improved on the original invention by reducing the crude powder to grains, and blending the various ingredients according to certain rules of composition. That this was the case, appears from several Arabic manuscripts deposited in the *Escorial* library, and particularly from one (No. MDCXXXIV), of which the author (who flourished in the year 1240) thus describes the various instruments of destruction by fire used in his time among the Arabians: "Scorpions (says he), twisted round and blazing with *nitrous powder*, creep along, hissing as they go, and at length exploding, they send forth flames like lightning, and burn: then you may behold a *manganum* discharged, stretching like a cloud through the air, making a noise like thunder, and vomiting out fire on all sides, overthrowing, burning, and reducing all things to ashes."

From this passage it would appear, that our author alluded to the globes or bombs of iron, burst by means of artificial fire; for he uses the words *naphtha* and *barud*, of which, in those times, gunpowder was composed. By the word *barud*, the Persians, Turks, and Arabians, formerly understood *nitre*. At present they use it to express *nitrous powder*, or gunpowder. *Naphtha* signifies a kind of bitumen mixt with sulphur. A noble writer of Granada, *Abu Abdallah Ebn Alkatib*, in his *History of Spain* (about the year of Christ 1312 and 1323), speaking of the globes or balls exploded by means of *naphtha* over the heads of enemies, has the following passage: "Abalvalid Iismael ben Nasir, at that time king of Granada,

moving his camp, laid siege to the town of *Beca*, where he exploded at the fortified tower, by means of fire, an immense machine furnished with *naphtha* and a globe or ball, making a loud noise."

That the use of such instruments of war obtained among the Arabs, may be gathered from the *Chronicle of Alfonso XI.* cap. 223, wherein we read, that whilst *Algezira* was besieged (in 1380), the Moors discharged many *peals of thunder* upon the army, casting iron balls equal in size to very large apples, some of which went so far as to pass the station of the troops, &c. In the same work (cap. 227) the matter is more clearly expressed: "In the year 1382, five vessels entered the port, laden with corn, honey, butter, and the powder with which *thunder was darted forth*," &c.

Of the former transaction Peter Mexia takes notice in his *Sylva Varie Lectionis*, lib. 1, cap. 8; but he is silent on the other: proving, however, the great antiquity of those machines (in the edition of his work published in 1570), he mentions a sea fight between the Tunisians and Spaniards, in which the ships of the Mahometans were furnished with iron ordnance, or *bombardas*, discharged by means of fire, with great effect upon the enemy. From this circumstance the author infers, that the instruments of destruction which we now denominate *artillery*, must have existed among the Mahometans above four hundred years ago, but less perfect than at present (1570).

There is also a passage of *Elmakine* (translated from Arabic into Latin, by Erpenius), which shews that the use of gunpowder was known to the very ancient Arabs; for he tells us, that in the year of the *Hegira* 71 (of Christ, 690), *Hejaje* besieged Mecca, and destroyed, by means of fire, the holy Caaba, using *manganas* and mortars, with fire and *naphtha*.

To these may be added the testimonies of European writers (apud Fabric. Biblioth. Antiq. p. 636). *Hyde*, in his *Hist. Shahiludii*, p. 175, informs us, that the Indians had for many centuries the use of gunpowder, and of machines for sending forth fire; and that the Chinese learned the knowledge of them from the Indians; and it appears in his *Var. Observat.* p. 89, that the Saracens learned it from the Chinese; and Joinville, an eye-witness, acknowledges that the Saracens used instruments of fiery destruction against St. Louis, king of France.

GUNTOOR, one of the Northern Circars, in the peninsula of Hindoostan. It is also called *Mortinazagur* and *Condavir*, and occupies the space between *Condapilla*, the southernmost of the four English Circars, and the N. part of the Carnatic; extending more than 30 miles along the bay of Bengal. The maritime parts of this circar are flat and open, but the interior parts contain some very strong fortresses and posts. It is subject to the Nizam of the Decan.

GUNTZBERG, a town of Suabia, in the Margravate of Burgaw, with a castle, seated on the Danube, 16 miles N.E. of Ulm. Long. 10. 25. E. Lat. 48. 35. N.

GUNTZENHAUSEN, a town of Franconia, 5 miles from Weissenburg. It is seated on the Altmul, near a forest, and subject to the King of Prussia.

GURIEF, a town of Russia, in the government of Astracan, seated near the Caspian Sea, between the mouths of the Ural, 210 miles E. by N. of Astracan. Long. 52. 50. E. Lat. 46. 32. N.

GURRAH, a town of Hindoostan Proper, situate near the river Nerbuddah, 168 miles S.S.W. of Allahabad, and 208 S.W. of Benares. Long. 80. 23. E. Lat. 23. 9. N.

GURRAMCONDA, a town of the peninsula of Hindoostan, in the kingdom of Myfore, 73 miles N.E. of Bangalore, and 112 N.N.W. of Madras. Long. 78. 36. E. Lat. 13. 47. N.

GUSTROW, a city of Germany, in the duchy of Mecklenburg-Schwerin, and capital of the circle of Wenden. The chief courts of judicature for the duchy are held here; and it has an elegant palace, in which the dukes sometimes reside. It is 35 miles E. by N. of Schwerin. Long. 12. 13. E. Lat. 53. 57. N.

GUTTA, a town of Hungary, seated on the E. side of the Danube, opposite the island of Schut, 25 miles E. by S. of Presburg. Long. 17. 47. E. Lat. 48. 10. N.

GUTSKOW, a town of Swedish Pomerania, capital of a county of the same name. It is seated on the Peene, 14 miles W. of Wolgast. Long. 13. 39. E. Lat. 54. 0. N.

GUZERAT, a peninsula of Hindoostan Proper, 200 miles long and 140 broad, formed by the Arabian Sea and the gulfs of Cambay and Cutch. The west part is mountainous and woody, inhabited by a wild hardy race, and governed by rajahs of their own; but the largest and finest part is included within the extensive empire of the Maharrattas. Amedabad is the capital.

GWALIOR, an ancient fortress of Hindoostan Proper, in the province of Gohud. It stands on a vast rock, about four miles in length, but narrow and of unequal breadth, and nearly flat on the top. The sides are so steep as to appear almost perpendicular in every part; for where it was not naturally so, it has been scraped away; and the height from the plain below, is from 200 to 300 feet. The rampart conforms to the edge of the precipice all around; and the only entrance is by steps running up the side of the rock, defended on the side next the country by a wall and bastions. The area within is full of noble buildings, reservoirs of water, wells, and cultivated land; so that it is a little district within itself. At the N.W. foot of the mountain is the town, pretty large, and well built, the houses all of stone. This place is considered as the Gibraltar of the East; but, in 1780, Major Popham took it by an unexpected nocturnal escalade. It is 80 miles S. of Agra. Long. 78. 30. E. Lat. 26. 9. N.

GYPHORN, a town of Lower Saxony, in the duchy of Lunenbug, seated on the rivers Aller and Iser, 25 miles N. of Brunswick. Long. 10. 49. E. Lat. 52. 49. N.

H.

HABITATION, a general name given to any dwelling or place of residence calculated for shelter and domestic accommodation. The term, however, is most commonly applied to dwellings of an inferior order: such as the low houses and cottages in which the poor reside. The following observations on the situation of cottages, with a plan for enabling cottagers to build them, is extracted from "An Address to the Landed Interest," by William Morton Pitt, Esq. M.P. published in 1797.

"There are few parishes," says the author, "without several rough, encumbered, and uncultivated tracts of land, which might be converted into large gardens, and on which cottages might be erected, either by some of the poor themselves, to be held on lives, or at the expence of the parish, or of the proprietors of estates. Where there is no land uncultivated, other grounds, which can be most conveniently spared, should be allotted to them. Many young men, having saved a little money, would be very desirous of taking such spots of ground on leases for three lives, and of building cottages thereon. I have frequently remarked that the labourers who possess this kind of property, are the most industrious, sober, and frugal, that they seldom apply to their parishes for relief, and that their houses have an appearance of neatness and comfort, not often met with elsewhere. If these were more attainable by the poor, frugality would revive amongst them, and young people would strive to lay up a sum of money for this purpose. Every labourer possessing such property of his own, would consider himself as having a permanent interest and stake in the country. The hope of improving their lot is the main spring of industry in all other stations in life. Would it not then be policy as well as humanity, to afford to the agricultural poor the same opportunity? The wealth and greatness of this country has been attributed, not only to the spirit of enterprise of our merchants and manufacturers, but to the effect which the possession and the security of property, enjoyed under our free and excellent constitution, have on the minds of men. If this effect has been so salutary among other classes, why may not similar encouragement create the same energy among the cultivators of the land; and why should those alone remain in a dispirited, and distressed state?

"To attach this numerous, hardy, and less corrupted body of men more and more to their country, nothing would so much contribute, as allowing them the means of improving by industry their own situation in life, or that of their children. A man who owns a house, with a large garden annexed to it, on a lease for lives, for which he only pays a moderate quit-rent, is richer by far than he who receives much higher wages, but who has to pay a considerable rent for a cottage, with little or no garden ground, and who is obliged to purchase all he consumes. The produce of a garden diminishes the consumption of bread, which is the most considerable article of a poor man's expenditure: it is an advantage wholly created by the cultivator's industry, at times when not otherwise engaged, and by that of his wife and children; and is therefore so much labour, or in other words riches, gained to the community: and the employment gives health and vigour to his children, inures them to fatigue, and trains them to industry. The value to him who receives the ground is immense, yet it is no loss to him who

grants it. It procures the poor man comfort and plenty; and, by so doing, keeps within moderate bounds the wages of labour. Every man, who is averse to raising the wages of labour in husbandry, should at least encourage the culture of gardens.

"As the land, on which such cottages would be built, will usually be of an inferior value, it will be enough to estimate it, at an average, at 10s. an acre; where the land is better, a higher rent may be added without injustice; for, the better the land, the greater will be the advantage to the lessee from its produce as a garden. The quantity of land to be attached to such a cottage should be half an acre; if it be more than sufficient to produce the vegetables wanted for a family, a part of it may be sown with a little wheat for bread, pease to fatten the pigs, and barley for malt, to enable them to brew a little small-beer; the want of which induces many to frequent the alehouse, and proves the source of vicious courses.

"The corn in these gardens should be raised by dibbling, which is already very much practised in many parts of the kingdom. The cultivation of the garden will be chiefly conducted by the wife and younger children of the family (who will thus very soon contribute largely to their own support, if not wholly maintain themselves, so that a numerous offspring will cease to be a great burthen), to which must be added a certain proportion of assistance from the father, at his extra hours. Where 10s. an acre is the value of the land, 5s. per annum must of course be added, for the half acre of ground, to the quit-rent for the house. Let that be 5s. and the whole annual payment will be 10s.; and, when it is considered that the proprietor of the estate has been at no expence whatsoever in building or repairing the cottage, and that he receives annually the quit-rent for the house, in addition to the full rent of the land on which it is built, I think the fine, to be required in putting in a life, should not exceed one year's purchase, computed on the real value. The cottager then, who builds a house upon this principle, acquires the following advantages; permanency of property, that all improvements are for the benefit of himself and his family, respectability of situation, a diminution of annual expenditure, and that he cannot be removed under any circumstances.

"This arrangement will answer in all cases, where a labourer has a sufficiency of money to enable him to build a cottage; but that cannot be the lot of all. Yet a plan may be devised, by means of which, a man, having but a small proportion of the sum requisite for such an undertaking, may be enabled to adopt it. The owner of the land may, without risk, advance to any labourer in want of such assistance, 10l. or even 15l. towards carrying on his work, not to be paid to him in money, but laid out for his use as wanted, in the purchase of materials, or in wages to the workmen whom he is obliged to call in to assist him in the construction of his house. The cottage itself would be a sufficient security for the loan; since the money will only be issued, in proportion, as the work advances. The cottager should pay interest, at 5 per cent. and part of the principal, at least 10 per cent. every year. If he fail in making these payments, his effects should be liable: or, if the demand be not otherwise satisfied in a reasonable time, the house itself. The sooner he discharges his debt, the better it will be for him; and he will look forward with

impatience to the time of its liquidation, that he may enjoy the effects of his industry and so comfortable a situation. In 10 years, however, at all events, he will be clear from incumbrances, and in the mean while he will have to pay each year not more, and in many parts of England not so much as he would have given as annual rent for an ordinary cottage. The landlord would also be benefited, by being relieved from the expence of repairs, and by the reduction of poor's rate; he would receive his quit-rent annually, and a fine from time to time, in addition to the full rent of his land, as well as 3 per cent. interest on the money lent, the whole debt being discharged in 10 years at furthest."

To these judicious remarks we shall annex some observations on the larger sort of cottages, and the mode of erecting them, extracted from "Hints to Gentlemen of Landed Property," by Nathaniel Kent, Esq. published in 1775.

"The larger sort of cottages," says Mr. Kent, "which may sometimes be preferred, will cost, when built of brick and tiles, 70*l*. These might be appropriated to the use of labourers of the most industrious disposition. And, as it would have an excellent effect to make some gradation among cottages, as well as farms, it would be highly proper, and useful, to lay (besides half an acre of garden-ground) a small portion of pasture-land, about 3 acres, to each of these larger cottages, to enable the occupiers of them to support a cow; which would be a real comfort to their families, as milk is the natural food of children. If we value these three acres and a half of land at a guinea an acre upon an average, and add it to the rent of the house, it will bring the rent to 6*l*. 9*s*. 6*d*. The value of the cow, if her produce were even sent to market, would at least amount to 4*l*.; but being used in the family, would, with the assistance of the garden, enable them to keep a sow, or two store pigs, which would at least double the market price. As one acre or more of this ground might be mowed every year for hay, the cow might be kept in good order with this quantity; and it would be better worth a cottager's while, to give this rent for this lot of land, than to trust to the precarious advantage of a common, which always starves his cow in the winter. If it should be alleged, that there is not one cottager in twenty who can afford to buy a cow; this difficulty may be easily obviated, by the landlord's letting him a cow, as well as the land; in the manner that dairies are generally let.

"This would be dealing with the poor as we would wish to be dealt with ourselves, in a similar situation; but, instead of this, cottagers are chiefly left by gentlemen to the farmer's disposal; and, when they are accommodated with a small quantity of land, are obliged to pay, at least, a double proportion of rent for it, to what the farmers pay themselves.

"Warm cottages of this sort would require much less fuel than those in the present style, which is a very considerable article to a cottager.

"The next consideration is, to choose a convenient situation for cottages. Great farmers are very unwilling to admit them close to their farms; and nothing is more common, than for a poor labourer to be obliged to come a mile, and sometimes more, to his labour, and return home again at night, in all kinds of weather, after he has done a hard day's work. Cottages should therefore be erected, if possible, on some sheltered spot, near the farm where the labour lies; and

such policy points out, that every farm ought to have a sufficient number of such useful appendages, in proportion to its size. Such cottages, under some such regulations as these, would be of great use and ornament to a country, and a real credit to every gentleman's residence; as, on the contrary, nothing can reflect greater disgrace upon him, than a flattered miserable hovel at his gate, unfit for human creatures to inhabit. Upon encouragement like this good tenants would never be wanting. Industry would meet with a reward, the poor-rates would necessarily be lightened, and population increased. A farm thus provided with such a sufficient number of labourers as might, at all times and seasons, be depended upon, would be of more value on that account. The tenant of such farm would not be subject to pay exorbitant wages, as he otherwise must, on particular occasions. He would not be obliged to court the vagrant to lend him a precarious assistance, or to have recourse to towns, to pick up disorderly people. In summer, besides the usual business of haymaking, he might employ even the women and children, in wedding, and other usual business.

"Almost every parish is, in a great measure, subject to some particular gentleman, who has sufficient power and influence over it, to correct the present grievance, and to set a better example. Such gentlemen should consider themselves as guardians of the poor, and attend to their accommodation and happiness: it is their particular business, because they and their families have a lasting interest in the prosperity of the parish; the farmers only a temporary one. If a gentleman's fortune be so large, that he cannot attend to objects of this sort, he should, at least, recommend the cottagers to the attention of his agent; and give him strict instructions, to act as their friend and protector: for unless some such check be put upon great farmers, they are very apt to contribute to the demolition, instead of the protection of cottages; and when the nest is destroyed, the bird must emigrate into some other parish. A cottager, in this case, has no other choice, unless it be to make application to the neighbouring justice of the peace, for his order to the parish-officers to find him some other place to lay his head in. If it were not for this excellent law, which obliges parish-officers to find habitations for their poor, I am sorry to remark, that in many parishes they would be literally driven into the open fields.

"There is another plan relative to cottages, which generally answers extremely well, and that is, to lease them off to industrious labourers, for the term of three lives, at their nomination; taking a very moderate fine, not exceeding 10*l*. or 12*l*. upon a cottage worth about 40*s*. a-year; reserving a small quit-rent, not exceeding half a crown a-year, and making it a point to renew any life which drops off, upon one year's value only. This scheme is beneficial for landlord and tenant; for though the farmer does not let his cottages for so much as he might at rack-rent, yet what he does get is all clear money; and by this means he preserves the value of all other parts of his estate, by keeping up a proper number of inhabitants. The latter finds his account in it, because he makes a settlement for his family; and can repair and improve his cottage at leisure hours with his own hands; and if he be an industrious man, he can generally find a friend to lend him his first fine on such an occasion, if he cannot raise it himself.*

*"I am persuaded that if there were a certain number of comfortable cottages, with two or three acres of grass land each, in proportion to the size of the estates, to be bestowed as a reward to labourers of particular good conduct, it would do wonders towards the reduction of the rates, and the preservation of order; for I have been witness to several striking proofs of this, in two or three labourers, who have been thus favoured; whose attachment to their masters was exemplary, as they were not only

"I should recommend that cottages should be built double; because it will be a considerable saving in the expence of their erection.—Where pollards are plenty, and bricks scarce, it will sometimes be proper to prefer the wooden-lath and rough-cast cottages, because half the quantity of timber may be pollards; but, where they are built with brick, the following particulars should be attended to:

"The walls should be fourteen inches thick to the bottom of the chamber-floor, except in the window spaces; and the upper part of the walls nine inches. In these brick buildings no framed timber should be used; but the lintel of the windows should be laid the whole length of the building, nine inches scantling by two and a half; and then the same piece will serve to lay joists upon, which should be pinned with oaken pegs, which will prove a great tie to the walls. The joists should be cut eight inches by two and a half, and laid edgewise. The length of the spar to be 10 feet, being a proper pitch for tiling; and to be cut two inches and a half thick, five at bottom, and three and a half at the top. The lower rooms to be seven feet high, in the clear, under the joists. In the largest sized brick cottages, the roof to be hipped in at the ends, which will save the two peaks of brick-work, and will not require more tiling, than would be made use of without it. One great advantage derived from hip-ping, is, in the building's being better braced together, and more secure from the effect of tempests; for, where the gable ends are carried up in peaks, to any considerable height, without chimneys to strengthen them, they are not so well fitted to resist an end-wind.

"The ceiling should be between the joists, nailing first a few laths at about a foot apart, cross-ways, and the other laths length-ways over them; otherwise the mortar has nothing to get hold of. This makes less expence than ceiling over the joists; and is besides better calculated to retain the mortar, and will afford more space; for the joists, being left naked, will be very useful to hang many things to. The ceiling joists upon the top of the chamber need be only five inches by one and a quarter, and may be nailed to the spars-feet, and not pinned. The other scantlings are as follow: The partition studs three inches by two. The lower cills six inches by five. The window-frames three inches by three. Lower door-sashes five inches by four. Cross mantle-pieces for the chimneys eight inches by eight.

"In the wooden cottages, the frame-studs are to be six inches by five. The intermediate, or smaller studs, five inches by three. The girt-pieces six inches by five, and the upper cill five inches square."

HABITE and REPUTE, in Scots law, the common opinion of the people, among whom a person lives, with respect to any circumstance relating to him.

HADAMAR, a town of Germany, in Weteravia, with a castle, seated near the Elbs, 22 miles N.W. of Mentz. Long. 8. o. E. Lat. 50. 23. N.

HADLEY, a village in Essex, five miles S.W. of Rochford. Here are some considerable ruins of a castle, on the brow of a steep hill, on a channel of the Thames between Canvey Island and the shore.

HADLEY, a village in Middlesex, N. of Barnet. Over the west floor of the church is the date 1498, and on the top of the steeple is an iron pitch-pot, originally placed there as a beacon.

HAGENBACH, a town of Germany, in the palatinate of

the Rhine, 12 miles S.E. of Landau. Long. 8. 7. E. Lat. 48. 50. N.

HAGENBURG, a town of Westphalia, in the county of Schaumburg, 15 miles W. of Hanover, and 46 S.S.E. of Bremen. Long. 9. 7. E. Lat. 52. 30. N.

HAGGERSTOWN, or **ELIZABETH TOWN**, a flourishing town of Maryland, in the fertile valley of Conegocheague. It carries on a considerable trade with the western country, and is 73 miles N.W. of Baltimore.

HAGIAR, a town of Arabia Deserta, 87 miles N. of Medina. Long. 39. 25. E. Lat. 25. 30. N.

HAILBRON, a free imperial town of Suabia, in the duchy of Wirtemberg. The inhabitants, who are Protestants, derive a great advantage from the baths near it, whence the town has its name, which signifies the fountain of health. It is seated on the Neckar, over which is a stone bridge, 25 miles N. by E. of Stuttgart. Long. 9. 15. E. Lat. 49. 9. N.

HAIMBURG, a town of Lower Austria, on the Danube, 10 miles W. of Prefburg, and 25 E. of Vienna. Long. 16. 58. E. Lat. 48. 12. N.

HAIN, a town of Upper Saxony, in Misnia. It has a manufacture of cloth, and is seated on the Rhedar, 12 miles N.W. of Dresden.

HAINBURG, a town of Austria, on the Danube, 35 miles E. of Vienna. Long. 17. 18. E. Lat. 48. 14. N.

HAINGEN, a town of Suabia, in the lordship of Gundelfingen, 21 miles S.W. of Ulm. Long. 10. 2. E. Lat. 48. 12. N.

HAIR-POWDER. On the licence for wearing this, there is a tax of one guinea per annum, with the following exemptions: Nothing in the act shall extend to any of the royal family, or to any of the immediate servants of his majesty, or any of the royal family, serving in any of the capacities described in the act imposing a duty on servants.

Neither shall it extend to charge any clergyman who shall not be possessed of an annual income of one hundred pounds, or upwards, whether arising from ecclesiastical preferment or otherwise. Nor any preacher of any congregation of Dissenters, or any person dissenting from the church of England in holy orders; or pretended holy orders, entitled to the benefit of the several statutes made for the relief of dissenters; or persons professing the Popish religion; and who shall not be possessed of an annual income of one hundred pounds or upwards, however arising.

Neither shall the act extend to charge any subaltern or non-commissioned officer, or private man, in the army, artillery, militia, marines, corps of engineers, or fencible corps;—nor any officer employed in the navy under the rank of commander;—nor any officer or private man in any corps of yeomanry or volunteers, either cavalry or infantry, *voluntarily enrolled for the defence of the kingdom during the war.*

Parents having more than two unmarried daughters, being assisted for them in twice the duty of a single person wearing hair powder, such assistance shall exempt the whole.

Persons claiming exemption are to prove their right; and the income of beneficed clergymen is to be estimated on the average of seven years.

If a master pay the hair-powder duty for his servants (returning a list), they shall be exempted from it during their continuance in his service, and their successors during the year for which it is paid.

steady in themselves, but by their example kept others from running into excess. *I know of no law that can enforce industry; it may be encouraged, and great good will result from it; but it never can be effected by compulsion.*"—*Kent's Agricultural Survey of Norfolk.*

HALDENSLEBEN, a town of Lower Saxony, in the principality of Magdeburg, 12 miles N. of Magdeburg.

HALLENBERG, a town of the duchy of Westphalia, 62 miles E. of Cologne.

HALVA, a town of the kingdom of Fez, seated on the Cebti, eight miles S. of Fez. Long. 5. 5. W. Lat. 33. 32. N.

HAMAR, a town of Norway, in the government of Agderhuys, 60 miles N.E. of Christiana. Long. 11. 5. E. Lat. 60. 30. N.

HAMARS, a town of France, in the department of Calvados, 13 miles S.S.W. of Caen.

HAMBACH, a town of Westphalia, in the duchy of Juliers, five miles S.E. of Juliers. Long. 6. 38. E. Lat. 50. 54. N.

HAMBACH, a town of the upper palatinate of Bavaria, six miles N.N.W. of Amberg. Long. 12. 10. E. Lat. 49. 33. N.

HAMBLEDON HILL, near Sturminster, in Dorsetshire. Here was a Roman camp, and many Roman coins have been dug up. It is the antagonist camp to that of Hog Hill, and extends E. and W. three quarters of a mile.

HAMBURGH (*Encycl.*). The following is extracted from an account of the management of the poor at Hamburg, by that truly benevolent prelate, the Bishop of Durham.

In the beginning of the year 1788, an infirmary was formed for the poor at Hamburg. Of 110,000 * inhabitants in Hamburg, there were above 7000 distressed persons in want of regular relief, besides an average of 2500 in the hospitals.—There were peculiar circumstances attending this great and commercial city, which contributed to increase the number of poor, requiring assistance;—severe winters, heavy taxes on the necessaries of life, fluctuation of trade, the attraction of the poor from neighbouring countries in expectation of employment; and a great number of female servants at very low wages, of whom many must necessarily remain unprovided for, when age or sickness should unfit them for active service.

As soon as the outline of the plan was agreed upon, an arrangement was formed, that such revenues as till then had been expended in alms by the several churchwardens, and those the administration whereof had been connected with the workhouse, should be united under one administration with the monies to be collected from private benevolence. The most respectable inhabitants went round personally to collect subscriptions; and the town was divided into sixty districts, each being allotted to the care of three overseers; and the whole

being under the direction of a board, or committee of fifteen directors, elected from among the overseers.

The general object was to provide comfort and subsistence for the aged, and for those afflicted with incurable disease, or labouring under temporary sickness; to supply the means of occupation for those who could work; and, by giving education and employment to children, to afford the most beneficial relief to those burthened with large families.

For the reception of the aged, a public building, or asylum, was provided; but in cases where they had friends, who would receive them, they were allowed as much as their expense in the asylum would have amounted to. For the sick, and particularly for women at a period when they have the greatest need of charitable relief, medical assistance was provided. For the different districts in the town there were appointed five physicians, five surgeons, and five midwives, who upon notice were to attend the lodging of the patient, if not capable of going abroad. Food and medicine were immediately supplied, with so much attention and economy, that, in the course of the three first years, 12,660 poor persons had been attended in sickness, whole cure (including broth and an occasional supply of other food) had not cost more, upon an average, than 3s. 6d. each.

For a provision for the children of the poor, where, from the vice or the decay of a parent, no suitable home remained for the child, they boarded them in the houses of the better sort of poor. In other cases they allow the mother † a weekly sum for the younger children. They also prepared a warm room in every parish, and bread, milk, and potatoes in plenty; so that parents, who went out to work, might leave their young children there during the day, and thus prevent any obstacle to their own industry, or to that of their elder children. At the same time they came to a determination, "that no family should be allowed any relief for any child above six years of age; but that such child, being sent to school ‡, should receive not only payment for its work, but also an allowance in the compound ratio of attendance at school, good behaviour, and application to work." For the instruction of the children, three sorts of schools were opened:—the first for those who had no other employment; these were schools of occupation as well as instruction: the second, evening schools for the education of children who worked with their parents during the day;—the third were Sunday schools, which continued alike open to all, as well to those who had gone into service in Hamburg, as to children on the school list. The average number in these schools were 600; the expense of them about £,700. a-year.

The most difficult part of the undertaking still remained:—

* This account is extracted from an excellent publication on the subject by Mr. Voght, published in 1796, by Kay, No. 332, Strand; and from the twenty-third report of the directors, published in German at Hamburg in January, in 1798. The first is earnestly recommended to the attention of those who interest themselves in the welfare of the poor: the latter, it is hoped, the society will be able to get translated, and published for the perusal of the English reader.

† See Mr. Voght's excellent work, published by Kay, as above stated. His observations on the removal of children from their parents are feeling and judicious.—"We were averse (says he) to place the children in a general hospital, and the poor mothers would have been still more so."—May all the favourers of those houses, such as they are, seriously reflect whether the advantages they offer, can compensate for the education of the heart, which nature yields in those huts of poverty, where both parties become so necessary to each other; and where heroic exertions of parental and filial piety are not seldom become habitual. Would the humane and philosophical observer look through the rags of pale misery; calculate the sacrifices daily made there in many families, and amongst neighbours; and enjoy the rapture with which a mother embraces her son, whom she sees eagerly devour the crumb of bread that she had refused to her own wants; the annals of the poor might reconcile him to human nature, when disgusted with the list of crimes which blacken the page of its history.

‡ It should be observed that this was in a town, where children can attend school conveniently. In the country (we speak from observation) great prejudice, both to the health and to the morals of children, attends their being sent to and returning from a distant school, or manufactory, at early and late hours, and in all variety of weather and season.

that of procuring regular and suitable employment for those who could work; and of ascertaining who were, and who were not able. A resolution was adopted, "not to permit any one to receive a shilling, which he would have been able to have earned for himself; and at the same time to reduce the support of those, who required relief, below the scale of what any industrious person, in such circumstances, could earn." Printed queries were sent to the poor, the answers to which were written on the blank column of the page, verified by the evidence of their neighbours, and by the personal attendance of the overseer, or (where the state of health was in question) of the physician. Many of the queries were calculated to ascertain the average earning of each member of the family; but in this respect the truth was, for some time, very difficult to be obtained; it being the interest of the party, to make his capacity for work appear less than it really was.

A manufactory for spinning flax existed at that time in Hamburg. The proprietor gave it up to the institution, together with the stock, the teachers, and the experience of several years. As the poor who wanted relief, were chiefly women and children, this was adopted as their general work. The clean flax was sold to the women at a certain and low price; and the yarn which they spun, purchased of them at £.30. per cent. above the usual rate. To whatever fineness the yarn was spun, the whole profit was received by the poor. Every poor woman brought with her work a book, in which the pieces delivered in by her were noted; so that she thereby received a certificate of industry, and the institution had a regular account always before them of the employment of the poor. In the mean time, the men and larger boys (who were not the numerous or necessitous part of the poor) were employed in mending the roads, cleaning the streets, making rope yarn, and other labour, at a certain allowance per day.

After these general preparations were made, the committee conceived that they could now offer relief to all sorts of poor; as they had the means of enforcing the only condition required;—that of their contributing towards their own support, the degree of exertion which they were capable of. The overseers therefore went through the streets, and made enquiries if any inhabitants were in need of relief. Those who applied, if capable of work, were supplied with employment; if prevented by want of skill, they were admitted into a school opened for that purpose; and in the course of three months were taught to spin; being allowed for the first week a gratuity of two shillings: every week after, two pence less; and, in the twelfth week, dismissed with the donation of a pound of flax, and a spinning wheel.

The quantity of work, which the disabled poor were capable of, was easily and accurately ascertained by a week's trial at the spinning school. The result was produced weekly before a sub-committee; and the sum that each poor person could earn, was entered in a book: from that time they were paid weekly, what their earnings fell short of *s. 6d.* a-week, whenever it appeared by their book, that they had earned to the known extent of their abilities. The means of subsistence however, are much cheaper at Hamburg than in London.

In the proportion of two shillings a-week, an allowance was made for their lodging. But as this is paid every six months, and the pauper's allowance is weekly, it was thought proper (except in cases where the lodging was otherwise provided for) to retain four pence a-week, for the purpose of paying the landlord's rent; thereby keeping the poor out of

debt, and giving them a more comfortable habitation, than what otherwise they could have expected.

Clothing and bedding were at first much wanted; but in order to prevent their being pawned or sold, it was thought proper to mark them as the property of the institution, which the pauper was to keep while he behaved well. The committee purchased the materials by wholesale, and employed some of the poor in making them up. They were delivered to the pauper on the recommendation of the overseer, countersigned by the director of the district; or, to children, upon the recommendation of the sub-committee of the schools.

A complete list of the poor being at length obtained, public notice was given, in the month of October, 1788, that no deserving poor person could or would, in future, remain unnoticed. Instructions were very generally distributed among the poor, as to the mode of obtaining relief; and the public was intreated to inform the committee, if any pauper had not been duly attended to.—No such case has hitherto occurred.

It was established as a general rule, that three years' residence in Hamburg should entitle the party to relief; allowance being also made for accidents, illness, or child-bed; which, in all cases, were held to be proper objects of charity. A place of reception was opened for foreign poor, where they were taken care of for three days, and then discharged with the means of subsistence home. At the same time, in order to prevent the further influx of other poor, it was prohibited to receive any stranger, without informing the magistrate or overseer, under pain of bearing all the expence of supporting such stranger, if he should become an object of charity within three years.

These general regulations have been strictly adhered to for ten years; except in the cases of poor persons being ill, when they have sick tickets given them, which exempt them from the general rules; and during the most severe winter weeks, when a regular increase of allowance is ordered by the committee. But no inequality of distribution is ever admitted, whatever may have been the prior situation of the party. Those who had formerly been in a more respectable situation, continued to be the proper objects of private benevolence; of which no public institution ought to supersede the exertions.

The conduct of the institution is in the general committee, consisting of fifteen directors. They appoint four sub-committees from among themselves; one for manufactures, another for the schools, a third for clothing, and a fourth for the police of the poor. The sub-committees have each their separate officers, and keep distinct accounts, which are given in every month to the treasurer and the board.

Ten of the directors are selected; each one of them superintending six of the sixty districts, to receive from the overseers accounts of what is wanted in the respective districts for fixed support, for occasional relief, for accidents, and for discretionary assistance; which, when certified by the director of the district, is sent for payment to the treasurer; whose accounts are laid every month before the committee, and checked by the director's certificate. These ten directors may be considered as "the advocates for the institution," to prevent, in their several districts, excess of expence.

From the enquiries made at the commencement of the institution, it appeared that there were more than 4,000 women, 2,000 children, and 1,000 men, then in Hamburg in the utmost want of immediate relief. The whole number consisted of 7,391 individuals, and composed 3,903 families.

* The poor at Hamburg had been habituated to live almost entirely on a miserable beverage, which was called *coffee*, and sold in messes, with about half a pound of indifferent bread. This wretched substitute for food they took twice a-day. About

The first clothing of so great a number of destitute persons, would have exceeded the powers of the institution, but for the quantity of ready-made shirts and other apparel, which the ladies supplied with a liberal hand. Clothing and schools for instruction are now wanted only for the children.

The purchase of spinning wheels, and of other instruments of employment, and the support of schools where 500 grown persons were at the same time instructed in spinning, added to the allowance made to the poor for the loss of time while they were learning to spin, occasioned a very enormous expence at the commencement of the institution. But this was not of long continuance. The schools for teaching spinning to grown persons soon became unnecessary; 3,354 spinning wheels had been given to those who had proved themselves able to spin. These were employed in spinning, when more lucrative employment was not to be found. 2,000 poor, who at the time they entered the school could do nothing at all, have since earned from eight pence to twenty pence a-week, at times, and during hours, which were formerly entirely lost to them. The average of all expences attending the employment of the poor during three years, up to December, 1796, including the loss upon the sale of manufactured goods, has been only £611 per annum; and, in the worst cases that have occurred, the expence of enabling a pauper to earn five guineas a-year, has not been more than half-a-guinea.

It will not be a small recommendation to many persons, that since the year 1788 *scarce a beggar has been seen at Hamburg*. But there is another much more important circumstance; the decrease of sickness and misery among the poor. The average mortality of the medical institution at Hamburg, before 1788, had been above one in ten. In the year 1789, it was greatly reduced, and has since, by a gradual progress, diminished to less than one in twenty.—This and the extension of the schools, and of the benefit of the medical institution to persons not *actually entitled to relief*, has greatly diminished, and must still have a much greater effect in diminishing, the list of distressed poor, and in increasing the number of industrious and thriving citizens at Hamburg.

OBSERVATIONS.—The division of labour has not produced more extraordinary effects in a well-constructed manufactory, than the division of *attention* in a well-arranged institution. The giving to every acting member his peculiar and appropriate duty, not interfered in by any other person, as has been done with great effect at Hamburg, is of the utmost importance in every establishment. Those who have attended much to the conduct of charities, must have had frequent occasion to regret, that, even among the best-intentioned men, more time, and more power, is often wasted in the counteraction and controversion of petty and trivial measures, than in the furtherance of the real objects of the institution. This is the *friction*, the impediment of action, the obstruction to progress, which it is most essential to prevent; and it is in this respect, that the benevolent and enlightened founders of the institution at Hamburg, have been peculiarly judicious and successful.

The maxims adopted at Hamburg in the execution of their plan, are very deserving of attention:—"That every allowance, which supercedes the necessity of working, becomes a premium to idleness:—that labour, not alms, should be

offered to all who have any ability to work, however small that ability may be!—that one shilling, which the poor man earns, does him more real service than two which are given him:—that, if the manner in which relief is given is not a spur to industry, it becomes in effect a premium to sloth and profligacy;—and that, if the mere support of a pauper is above what any industrious person in the same circumstances could earn, idleness will become more profitable than industry, and *beggary* a better trade than the *workshop*." In proportion as the conductors of the institution at Hamburg have rigidly adhered to these maxims, they have found the benefit extended and increased; whenever they have relaxed, the *thermometer of industry* has been lower, and less work has been done.

One great cause of the success of the institution at Hamburg has been the *publicity* and *regularity* of the accounts. Without this all charities become jobs, the directors grow indifferent to public approbation or censure, and the administration falls into the hands of under officers, who soon learn to entangle the business, that no subsequent director is ever able to unravel the clue.

That which has been done in Hamburg, by the co-operation of its best and wisest citizens, has been effected at Munich by the abilities and perseverance of one truly distinguished individual, Count Rumford. (See *SOUP* in this Supplement.) The particulars of that establishment are so well and so generally known, that it is unnecessary for us to enter into the detail of them. The institution has, in both instances, been wisely adapted to the circumstances and condition of the respective places;—at Munich with additional power, from the establishment being blended with the government of the state, and producing an influence on the country, of which that city is the capital; and from its being connected with a variety of useful and extraordinary inventions and improvements, which Count Rumford has made, and is now making, for the benefit of mankind.

HAMERSTEIN, a castle and village of Germany, belonging to the elector of Treves. The castle is seated on a lofty mountain, on the E. side of the Rhine, two miles N. by W. of Andernach.

HANSBACH, a town of Bohemia, in the circle of Leitzmeritz, with manufactures of cotton, thread, and paper, 12 miles N. of Kamnitz.

HANSFELDEN, a town of Germany, in the duchy of Stiria, eight miles N.N.W. of Judenburg.

HAN-TCHONG-FOU, a large and populous city of China, in the province of Chenfi. It has 16 cities of the second and third class under its jurisdiction, and is seated on the river Han, 84½ miles S.W. of Peking. Long. 106. 55. E. Lat. 32. 45. N.

HAN-YANG-FOU, a populous and commercial city of China, in the province of Hou-quang. It has one city under its jurisdiction.

HARDBERG, a town of Germany, in the duchy of Stiria, 52 miles S. of Vienna. Long. 16. 12. E. Lat. 47. 22. N.

HARDEGEN, a town of Lower Saxony, in the principality of Calenberg, with a considerable manufacture of leather, 10 miles N.W. of Gottingen.

HARDENBERG, a town of Westphalia, in the duchy

two years ago, the directors introduced the use of Count Rumford's stoves, with great benefit to the poor at Hamburg. It has been a saving of 9 parts in 16, or rather more than half the former expence of their food. Children, in particular, have derived great advantage in health and strength from the use of these stoves. The saving to the institution in respect of fuel, by the introduction of Count Rumford's boilers, is stated in the Report (which contains a great deal of minute and curious detail in respect to fuel as well as food) to have been rather more than 61 parts in 66; the cost of their fuel, which is very scarce at Hamburg, being at present not a tenth of what it was.—*Hamburg Report of Jan. 1798.*

of Berg, 13 miles E.N.E. of Duffeldorp. Long. 6. 43. E. Lat. 51. 19. N.

HARDENBURG, a town of Overijssel, situate on the Vecht, 10 miles S.W. of Coevorden.

HARLEBECK, a town of Austrian Flanders, on the river IJis, three miles N.E. of Courtray. Long. 3. 29. E. Lat. 50. 52. N.

HARLESTON, a town in Norfolk, with a market on Wednesday, seated on the Waveney, 16 miles S. of Norwich, and 100 N.E. of London. Long. 1. 20. E. Lat. 52. 26. N.

HARMONSWORTH, a village in Middlesex, two miles E. by N. of Colnbrook. It is remarkable for one of the largest barns in England, whose supporting pillars are of stone, and supposed to be of great antiquity.

HARNESSE (*Encycl.*). The following is the specification of a patent granted to Mr. Dickinson, of Long-acre, for certain improvements in the construction of saddles, harnesses, and other gear, used for the employ of horses and other animals in riding or carrying loads, or in drawing carriages of any description. It is dated November 10, 1801.

"Whereas (says the inventor), in the construction of the saddles, and other gear and appendages hitherto made or manufactured, the several parts have generally possessed no elasticity, except that slight degree which might depend upon the nature of the materials themselves, and it consequently follows, that saddles and cruppers are either girthed too tight, so as to impede the respiration of the animal, and so as to endanger their breaking, or so loosely as to render the seat of the rider more or less unsafe, and very seldom can be fixed with that exact degree of tension which is best adapted to every useful purpose. And, moreover, in the adjustment of the crupper, and with the breast-plate, a difficulty of the same nature presents itself, namely, that in the first tension of these, if the same be too loose, the saddle will not be duly confined to its place, or if the same be too tight, the animal will be very much incommoded, and in either case, when by sudden jerks, or other motions, the breast-plate or crupper, or girth, shall be required to produce their respective effects, the parts will either break, or else the action, particularly of the crupper upon the tail of the animal, will be sudden, unqualified, and pernicious. Now my said improvements in the construction of, and additions to the saddles, harnesses, and other gear aforesaid, consist in certain springs, or elastic portions, interposed between, and in effect constituting parts of the said instruments or parts; that is to say, more particularly, I improve the construction of saddles, by affixing one or more spiral springs, similar to those used in the small instrument for weighing, commonly called spring steel-yards, unto those parts of the saddle to which the girths, the crupper, and the breast-plate, are respectively to be fastened. The said spiral springs are so lodged in certain cavities, sheaths, or receptacles, that a piece of catgut or wire, or chain, or other fit material, passing within the cavity of the spring, and fastened to, or bearing against one end of the said spring, shall, when drawn or acted upon, cause the turns of the spring to approach more nearly together, and consequently cause it to react against the said catgut or rod, or chain, or other fit material, and tend to draw the same towards the saddle itself. I fix to the end of the said catgut, rod, chain, or other fit material, straps or buckles, or other fastenings, for the ready fixing of the girth, breast-plate, and crupper, in the usual manner. And moreover, in some cases, where convenience or choice may cause the preference, I fix the said spiral springs within proper sheaths or receptacles, of metal, wood, cloth, leather, or other fit material, so as to form a separate piece capable of being applied or attached between the saddle, and the extremity of the girth, breast-plate, or crupper, respectively, so

as to communicate to the said appendages the effect of its own elastic extensibility in the longitudinal direction or otherwise. I fix the said springs so fitted up in the breast-plate and crupper in such a manner, that the same shall constitute parts of those appendages to the saddle, and communicate the same effect as in the other cases just described. And further, I do hereby declare, that I do not confine myself in the structure and use of the springs or elastic parts of my said invention to any such precision of figure or material as not to allow of considerable variations. The springs may be made to act by drawing the convolutions or turns further apart, instead of compressing the same together, as before described. The wire of which the springs are made, may be taken of any fit metal, but steel is the best, and it may be either round, square, or of any other figure, as to its section or base, and the springs may be either straight or curved, according to the numerous well-known forms of springs, and the application thereof; but I consider the spiral or helix, as before described and applied, as the cheapest, most convenient, and as good as any. On some occasions I make use of a simple strap or piece of Indian rubber, or *caoutchouc*, instead of the springs; the use of which springs is supplied by the natural elasticity of the said *caoutchouc*; but I do not consider this last material as deserving any general preference, because its spring or elastic force is greatly weakened by heat, and in cold weather it becomes rigid, and liable to snap."

HARO, a town of Spain, in Old Castile, the chief place of a county; seated on the Ebro, 32 miles N.E. of Burgos. Long. 2. 23. W. Lat. 42. 40. N.

HARPONNELLY, a town of the peninsula of Hindoostan, capital of a district of the same name, in the Mysoor country, 152 miles N.N.W. of Seringapatam. Long. 75. 28. E. Lat. 14. 40. N.

HARRISBURG, a town of Pennsylvania, capital of the county of Dauphin, situate on the E. branch of the Susquehanna, 86 miles W. by N. of Philadelphia. Long. 76. 55. W. Lat. 40. 15. N.

HARRODSBURG, a town of Kentucky, in the county of Mercer, on the head waters of the Salt River, 60 miles S.E. of Louisville.

HARTENSTEIN a town of Upper Saxony, in the lordship of Schonburg, six miles S.E. of Zwickau.

HARTFORD, a commercial town of Connecticut, divided by a small river, over which is a bridge. It is seated on the W. side of the river Connecticut, 50 miles from its entrance into the Sound, and 30. S.W. of Boston. Long. 72. 35. W. Lat. 41. 50. N.

HARTZGERODE, a town of Upper Saxony, in the principality of Anhalt-Bernburg, situate near the Hartz mountain. The walls and houses are built of a motley kind of marble. It has a mine office and a castle; and is 24 miles S.W. of Bernburg, and 44 W.S.W. of Dessau. Long. 11. 2. E. Lat. 51. 46. N.

HASLINDEN, a town in Lancashire, with a market on Wednesday, 16 miles N. by W. of Manchester, and 196 N.N.W. of London. Long. 2. 16. W. Lat. 53. 40. N.

HASTENBECK, a town of Lower Saxony, in the principality of Calenberg, near which the French, under Marshal d'Estrees, gained a victory over the Duke of Cumberland, in 1757. It is five miles S.E. of Hameln.

HAT (*Encycl.*). A patent was granted in January 1782 to Mr. Robert Golding, of Southwark, hat-dyer; for his method of dyeing, staining, and colouring beaver hats green, or any other colour. The inventor directs the nap of the hat to be raised by means of a card, on the side intended to be dyed, and then boiled in alum argol. A thin paste should be made of flour, or clay, which is spread over every part that is not

to be dyed, and then closed; or the hat may be previously puffed, and instead of being boiled, it should only be simmered in the same liquor. As soon as the paste is spread, plates of copper or other metal, shaped like a common funnel, are fixed over the paste, to prevent the dye from penetrating through. In this state the hat is immersed in the dye, till the colour be sufficiently fixed; when it is taken out, opened, and cleaned from the paste: but if any colouring particles have penetrated through the felt, they may be removed by rubbing them with a small quantity of spirit of salt, aqua fortis, &c. The compounds employed in dyeing, are fustic, turmeric, ebony, saffron, alum, argol, indigo, and vitriol, with urine, or pearl-ash, at the option of the dyer; all of which are used together, or separately, according to the colour required.

Among the different patents granted to hatters, for discovering new materials in this manufacture, such as that of Mr. J. Burn, in 1792, for *mole-fur*; and another to Mr. J. Tiltstone, in 1794, for *kid-hair*; we shall first notice an invention of Mr. George Dunnage, who, in November 1794, obtained a patent for his *Water-proof Hats*, in imitation of beaver.

The articles he employs are similar to those commonly used for the making of hats, with which he mixes Bergam, Piedmont, or Orgazine silk. These are dressed and worked in a peculiar manner; though we understand that hats thus prepared become heavy and oppressive to the wearer, while they acquire an ugly colour.—The curious reader will find the patentee's specification inserted, at full length, in the 4th vol. of the *Repository of Arts and Manufactures*. The same manufacturer procured another patent in November 1798, for a method of ventilating the crowns of hats. This invention consists in separating the top from the sides of the crown, so that the tip, or top-crown, may be either raised or let down at pleasure, in order to admit the external air, or to exclude it from circulating in the crown of the hat. The whole contrivance is effected by means of springs, sliders, sockets, grooves, loops, and cables, which are connected with the top and side-crown: thus the admission or exclusion of atmospheric air in front, behind, or on either side, may be regulated accordingly.—As this invention is ingenious, we refer the reader to the 10th vol. of the work last quoted, where he will find a minute account given of it.

The following is the specification of a patent granted to Messrs. Walker and Alphey, for making and manufacturing caps and hats, and rendering them perfectly water-proof; as also all kinds of leather, silks, linen, cotton, stuffs, pasteboard, and other manufactures and substances, for the purpose of being worked up into boots, shoes, gaiters, women's hats or bonnets, and other wearing apparel, so as to be used on all occasions, where the repelling of wet or moisture may be required. It is dated November 3, 1801, and the patentees express themselves in the following terms:

"For the making and manufacturing of our new-invented caps, which are principally intended for the use and wear of the military, we take a suitable piece or pieces of manufacture, called pasteboard; and cover both sides thereof with linen cloth, or any other texture wrought in a loom, which we cement thereto by glue or paste, or paste and glue mixed, out of which the cap is then cut and shaped on a block, or otherwise, according to the shape and fashion the same is ordered to be made, and as circumstances may require. The seams or joinings of the pasteboard are united by sewing, and by glue or paste, or paste and glue mixed; and also by slips of leather, linen, or other wove texture, glued or pasted over the same, both inside and outside, where found necessary. It is then painted both inside and outside,

with any kind of oil-paint, or oil and lamp-black (which latter is greatly to be preferred), with one or more coats, as circumstances may require: when this is dry, it is then to be covered with one or more coats of Japan or varnish, mixed with lamp-black or ivory-black. The peak or rim of the cap, together with the cape behind, agreeable to the quality and fashion ordered to be made, is also to be painted, japanned, or varnished, on one or both sides, as may be thought necessary, in like manner as the other parts of the cap are. When the peak or rim, together with the cape and lining, are affixed to the crown, in the usual manner, the cap is then finished, exclusive of any ornament or ornaments that may be thought proper to affix to the same. The men's hats are made in the same manner, and with the same materials as the crown of the cap, except being principally covered with silk, linen, cotton, or other texture, wrought in a loom, cemented to the pasteboard in like manner as described for the cap. And also except that such breadth is given to that side or inner part, or edge of the flap, or rim, that is next the crown, as will admit of its being notched and turned up; so as to lie close to the side of the crown, and is to be united thereto by sewing. And, with the same cement as applied to the cap and other articles, the parts so turned up, sewed, and cemented to the crown, are to be covered with leather, or any texture wove in a loom: the whole is then to be painted, japanned, or varnished, on one or both sides, as may be thought proper, and in like manner as the caps. The preparation of leather for boots, shoes, gaiters, or other articles where a power of repelling wet is required, is to be painted, japanned, or varnished, in like manner as the caps are, on one or both sides as may be found necessary. When this operation is performed upon leather, it must be upon such leather only which has not been dressed with oil, or any other greasy substance. The preparations of pasteboard, and silk, linen, cotton, stuffs, or any other texture wrought in a loom, for the purpose of making shoes, gaiters, women's hats or bonnets, are to be painted, japanned, or varnished on one or both sides, as may be found necessary, in like manner as the caps are herein-before specified to be done."

The following duty on hats commenced October 2, 1784, by the act 24 Geo. III. c. 51.

	£. d.
Licence to sell hats retail in London, Westminster, Borough, and within the Bills of Mortality	2 0 0
Ditto in other parts of the kingdom	0 5 0
No hats to be sold without such licence, under forfeiture of	50 0 0
And "Dealers in hats" to be written over the door, under forfeiture of	2 0 0
Duty on every hat of 4s. or under	0 0 3
Ditto above 4s. and not exceeding 7s.	0 0 6
Ditto above 7s. and not exceeding 12s.	0 1 0
Ditto above 12s. and upwards	0 2 0

And by the *New Act*, 36 Geo. III. c. 125, it is enacted that, after Aug. 5, 1796, the above duty shall be calculated according to the full price of the hat, and of all the mountings and other ornaments (except gold and silver lace) sold therewith.

And every hat made wholly of felt, wool, stuff, beaver, or leather, or any mixture therewith, shall be liable to the duties.

And every such hat, after Aug. 5, 1796, shall, previous to the sale and delivery, be lined or covered in the inside of the crown with silk, linen, or other proper materials, with a durable stamp affixed thereon to denote the above duties.

And, after Aug. 5, 1796, if any person (other than licensed dealers buying hats from other licensed dealers) shall

receive on sale, or if any person shall, after April 5, 1797, wear or use any hat wherein no lining or inside covering shall be affixed, or if the lining or covering shall not be stamped according to this act, or not have the stamp placed therein in a visible manner, every such person shall forfeit 10*l*.

And no person (other than manufacturers or dealers selling to other dealers) shall sell or exchange any hat wherein no lining or inside covering shall be affixed, or wherein there shall be a lining that shall not be stamped, or that shall not be stamped with a stamp placed in the inside of the crown so as to be visible, or that shall be stamped with a stamp of less value than required, on pain to forfeit 10*l*.

Persons carrying about hats for sale without any lining, or with a lining not duly stamped, may be apprehended and carried before a magistrate, and the apprehender, on conviction of the offender, is to be entitled to 40*s*, and the offender in such case is to be committed to the house of correction for not exceeding six nor less than two calendar months.

And if any person shall take out of any hat the stamped lining after the same shall have been used or worn, with intent to affix the same to any other hat, or shall affix any such stamped lining after the same shall have been used or worn, such person shall forfeit 20*l*.

Shapes for linings may be sent to the office to be stamped; and an account of the numbers brought, and the duties, are to be entered in a book, and the shapes to be then stamped, on payment of the duty. Or the commissioners may open accounts at the Stamp Office with dealers or manufacturers, and stamp the linings on credit, if such dealers or manufacturers enter into such bond as the commissioners shall direct for payment of the amount of the duty, at such times as the commissioners may fix, not being at less than two payments in the year.

And the commissioners are to make such regulations as they shall think fit, as well to prevent the concealment of the stamp upon the linings, as to prevent the stamps from being made use of again; which regulations, being printed, shall be delivered to all dealers upon their taking out their licence.

Dealers may send any number of hats, not less than one dozen at one time, wherein a lining shall then be affixed, to be stamped; and they may sell to other dealers lined hats for sale for home consumption, or to any persons for exportation, without being stamped.

Persons are not liable to penalty for wearing hats stamped according to the former act, if they were worn before Aug. 5, 1796; but proof of that, and also that the duty has been paid, lies on the owner of the hat.

Persons offending, discovering the other party, if convicted, freed from the penalty.

Stamped linings damaged, or stamps under the former act not used, may be cancelled by the commissioners, and exchanged for others.

Such discount to be made on purchasing stamps to the amount of 10*l*, as the commissioners of the Treasury shall direct.

Price of hats in bargains or bills to be distinguished from duties.

Hats, not less than a dozen in a package, may be exported unlined, or with unstamped linings.

Persons counterfeiting stamps, &c. guilty of felony.

The pecuniary penalties are to be divided (if sued for within the space of six calendar months), one moiety to his Majesty and the other to the informer; and may be recovered, with costs, either in the Court of Exchequer, or before one Justice of the Peace, in a summary way. And if witnesses neglect or refuse to give evidence, the penalty is 5*l*.

HATTENGEN, a town of Westphalia, in the county of

Marck, seated on the Roer, 17 miles E.N.E. of Duffeldorp. Long. 7. 14. E. Lat. 51. 17. N.

HATTENHEIM, a town of Germany, in the electorate of Mentz, situate on the Rhine, 12 miles W. of Mentz.

HAUENSTEIN, a town of Suabia, capital of a county of the same name, in the Austrian Brigau. The county contains rich mines of iron, and is divided into eight communities. The town is situate near the Rhine, 13 miles N.W. of Baden.

HAVERING BOWER, a village in Essex, three miles N.E. of Rumford. It was once the seat of a royal palace, in which died Joan queen of Henry IV.

HAUTE-RIVE, a town of France, in the department of Upper Garonne, seated on the Ariège, 10 miles S. of Toulouse. Long. 1. 26. E. Lat. 43. 26. N.

HAUTVILLIERS, a town of France, in the department of Marne, with a late famous rich abbey. It is seated on the Marne, 20 miles S. by E. of Rheims.

HAWICK, a town in Roxburghshire, seated on the Ti-viot, amid wooded rocks, cataracts, and bridges, 15 miles S.W. of Kelso.

HAWKERS (*Encycl.*). The following are abstracts from the Acts for granting duties on hawkers, pedlars, and petty chapmen; and for regulating their trade.

By 29 Geo. III. c. 26. from August 1, 1789, the following duties shall be paid by every hawker, pedlar, petty chapman, and every other trading person or persons, going from town to town, or to other men's houses, and travelling either on foot, or with horse, horses, or otherwise, in England, Wales, or the town of Berwick-upon-Tweed, carrying to sell, or exposing to sale, any goods, wares, or merchandizes, a duty of 4*l*. per annum.

Every person so travelling with a horse, ass, or mule, or other beast bearing or drawing burthen, the additional sum of 4*l*. yearly for each beast he or she shall so travel with, over and above the first-mentioned duty of 4*l*.

Persons applying for licences to produce a certificate of their good character, signed by the clergyman of the parish and two reputable inhabitants.

Hawkers are to mark on every pack, box, bag, trunk, case, cart, waggon, or other vehicle of conveyance, and every room or shop in which they shall trade, and likewise upon every handbill or advertisement which they shall distribute, the words *licensed hawker*, with the number, name, or other mark of distinction, written or printed upon the respective licences, in large Roman capitals, under a penalty of 10*l*. for every offence. Unlicensed persons so marking their packs, &c. to forfeit 10*l*.

Hawkers selling smuggled goods, or goods fraudulently procured, either by themselves or others, with their privacy or knowledge, shall forfeit their licences, and for ever be incapable of obtaining a new licence, over and above the penalties inflicted on illegal trafficking.

Nothing herein shall authorize any hawker to open a room or shop, and expose to sale any goods by retail, in any town, parish, or place, not being a householder there, or the same not being an usual place of his abode, or of his carrying on business, nor to sell any goods by auction, on the penalty of 50*l*. for every offence.

Every person forging or travelling with a forged or counterfeit licence shall forfeit 100*l*.

Every person lending or letting his licence to hire, and every person travelling or trading with a borrowed licence, shall forfeit 20*l*. and the licence of the person lending it shall be from thenceforth forfeited and void, and he or she shall be utterly incapable of having any licence again.

It shall be lawful for any person whatsoever to seize and detain any hawk who shall be found trading without a licence, or shall refuse to produce to such person a licence according to this act, or after being required so to do, for a reasonable time, in order to give notice to a constable, headborough, tithingman, or other peace officer, who are hereby required to carry such persons so seized, unless they shall in the mean time produce their respective licences, before some justice of the peace, who upon proof by confession of the party offending, or by the oath of one or more credible witnesses of the like offence, and no licence being produced by such offender before the said justice, he is required by warrant under his hand and seal to cause the said sum of 40*l*. [this is a mistake in the act, for the penalty of trading without a licence is only 10*l*.] to be levied by distress, rendering the overplus, if any, to the owner of the goods, after deducting the charges of the said distress.

It shall and may be lawful for any person or persons authorized by two commissioners, shewing that such authority, or upon demand of any justice of the peace, mayor, constable, or other officer of the peace where the hawk shall trade, or by any officer of the customs or excise, to demand any hawk found trading to produce a licence according to this act, and upon refusal, or not having his licence ready to produce, shall forfeit 10*l*. and for non-payment thereof the justice may, by 35 Geo. III. c. 91. levy the same by distress and sale of goods, and in the mean time he may commit the offender to goal, there to remain until the penalty is levied by distress, or until the same shall be paid thereon.

Every constable, &c. refusing to assist in the execution of this act, shall on conviction by the oath of one or more credible witnesses or witnesses before a justice of the peace, forfeit 10*l*. for each offence.

The clauses restricting hawkers from selling in market towns, except on a fair or market day, is repealed by 35 Geo. III. c. 91.

Hawkers, &c. who were licensed on May 1, 1789, may set up, occupy, use, or exercise, any craft, mystery, or occupation, in the place where they are resident inhabitants, though not brought up thereto by apprenticeship, and may employ therein persons who have not been apprentices, notwithstanding the act of 5 Eliz. and if they shall be prosecuted may plead the general issue.

Nothing in this act shall extend to prohibit any persons from selling any printed papers, licensed by authority, or any fish, fruits, or victuals, nor to hinder any persons who are the real workers or makers of any goods, wares, or manufactures of Great Britain, or his, her, or their children, apprentices, agents, or servants, from carrying abroad, exposing to sale, and selling by retail or otherwise, any of the said goods, wares, or manufactures, in any mart, market, or fair, and in every city, borough, town corporate, and market town; nor any tinkers, coopers, glaziers, plumbers, harness-menders, or other persons usually trading in mending kettles, tubs, household goods, or harness whatsoever, from going about and carrying with him or them proper materials for mending the same.

No wholesale dealer in British goods, selling by wholesale only from house to house, to be deemed a hawk.

Penalties above 20*l*. are to be recovered with costs in any of his Majesty's courts of record at Westminster, by action of debt, &c. one moiety to his Majesty, and the other moiety to the person who shall inform or sue for the same.

Penalties under 20*l*. shall be recoverable before a justice, either by confession of the party, or by oath of one or more credible witness or witnesses, and appropriated as above. And

in case of non-payment, shall be levied by distress; and if not sufficient distress, to be committed to prison for any term not less than one and not exceeding three months.

Persons aggrieved may appeal to the quarter-sessions.

Witnesses who shall neglect to appear, or refuse to be examined on oath, shall forfeit 10*l*. Defendants may plead the general issue, and recover treble costs.

HAWKINS (Sir John), was the youngest son of a man who, though descended from the great admiral of that name, followed the business of a carpenter, though he became afterwards a surveyor and builder. He was born in London, March 30, 1719, and educated for his father's profession; having, however, previously acquired some knowledge of Latin at two different schools. He changed his plan after this, and was articled to Mr. John Scott, an eminent attorney and solicitor, who, it seems, took little pains to make him acquainted with the practice of the law. This marked neglect, however, rather sharpened the diligence of his pupil, who, by abridging himself of his rest, and devoting all his hours of leisure to private study, not only rendered himself an able lawyer but acquired a knowledge of general literature, particularly of poetry and music, for which he had a natural taste. More especially to cultivate the latter, in the year 1741, he, with others, instituted a musical club under the name of the *Madrigal Society*; and he afterwards became a member of the Academy of Ancient Music.

His advancement in life was greatly promoted by his marriage with the daughter of Peter Stover, esq. of Highgate, in 1753; and his fortune was a few years afterwards considerably augmented by the death of that lady's brother in 1759, on which occasion he quitted the business of an attorney. In 1761, on the recommendation of his friend Paul Whitehead, his name was inserted in the commission of the peace for Middlesex; and he did himself much credit, not only as an active and useful magistrate, but by framing an act of parliament, now in force, for the repair of the highways. In 1763 he assisted Dr. Johnson, and Sir Johnna, then Mr. Reynolds, in forming a literary club at the Turk's Head in Gerard-street. In 1764 he stood forward as an opposer of the unreasonable claims, made on the public purse, by the city of London, on the rebuilding of Newgate. His opposition being successful, he was afterwards (in 1765) appointed to the vacant situation of Chairman of the Quarter-sessions; and in 1772 his activity, as a magistrate, in suppressing riots, at the time of the Middlesex elections, procured him the honour of knighthood. Dr. Johnson, who, at the commencement of Sir John's professional career as a solicitor, had occupied an apartment in his house, in Clement's-lane, Lombard-street, and who had always entertained sentiments of kindness towards him, on making his will, in 1783, appointed him one of his executors. Sir John Hawkins, as a literary character, was more remarkable for industry than genius. Besides contributing to an edition of Shakspeare by Johnson and Stevens, he wrote: 1. *The Complete Angler*. 2. *An History of the Science and Practice of Music*. 3. *The Life and Writings of Dr. Samuel Johnson*, in 11 vols. 8vo.: and also many fugitive pieces. He died on the 21st of May, 1789, of a palsy, and was interred in the cloisters of Westminster abbey.

HAWKSHEAD, a town in Lancashire, with a market on Monday, 24 miles N.N.W. of Lancaster, and 273 of London. Long. 3. 6. W. Lat. 54. 24. N.

HAWES-WATER, a lake in Westmoreland, S. of Penrith, three miles long, and half a mile over in some places. It is almost divided in the middle by a promontory of inclosures, so that it consists of two sheets of water.

HAYE, a town of France, in the department of Indre

and Loire. It is the birth-place of Des Cartes, and seated on the Creufe, 25 miles S. of Tours, and 135 S.W. of Paris. Long. o. 46. E. Lat. 46. 56. N.

HAYLSHAM, a town in Suffex, with a market on Saturday, 12 miles E. of Lewes, and 58 S.E. of London. Long. o. 20. E. Lat. 50. 55. N.

HAZEBROUCK, a town of France, in the department of the North, 18 miles W. of Lille, and 19 S. of Dunkirk. Long. 2. 26. E. Lat. 50. 43. N.

HEADFORD, a town of Ireland, in the county of Galway, 12 miles N. of Galway. Long. o. 3. W. Lat. 53. 29. N.

HEAD OF ELK, or ELKTON, a town of the United States, in Maryland, situate near the head of Chesapeake Bay, on a small river of its own name. It enjoys great advantages from the carrying-trade between Baltimore and Philadelphia, being about 50 miles from each.

HEAN, a town of Tonquin, on the river Domca, 20 miles S. of Cachao, and 80 N. of the bay of Tonquin.

HEAT (*Encycl.*). The following important observations on the use of steam as a vehicle for conveying heat from one place to another, by Count Rumford, are inserted in the Journals of the Royal Institution of Great Britain.

"More than fifty years ago," says Count Rumford, "Colonel William Cook, in a paper presented by him to the Royal Society, and published in their Transactions, made a proposal for warming rooms by means of metallic tubes filled with steam, and communicating with a boiler situated out of the room; which proposal was accompanied by an engraving, which shewed, in a manner perfectly clear and distinct, how this might be effected. Since that time this scheme has frequently been put in practice with success, both in this country and on the Continent*.—Many attempts have likewise been made, at different periods, to heat liquids by means of steam introduced into them; but most of these have failed: and, indeed, until it was known that fluids are non-conductors of heat, and, consequently, that heat cannot be made to *descend* in them (which is a recent discovery), these attempts could hardly succeed; for, in order to their being successful, it is absolutely necessary that the tube which conveys the hot steam should open into the *lowest* part of the vessel which contains the liquid to be heated, or on a level with its bottom; but as long as the erroneous opinion obtained, that heat could pass in fluids in *all directions*, there did not appear to be any reason for placing the opening of the steam-tube at the bottom of the vessel, while many were at hand which pointed out other places as being more convenient for it.

"But to succeed in heating liquids by steam, it is necessary, not only that a steam should enter the liquid at the bottom of the vessel which contains it, but also that it should enter it *coming from above*. The steam-tube should be in a vertical position, and the steam should *descend* through it previous to its entering the vessel, and mixing with the liquid which it is to heat; otherwise this liquid will be in danger of being forced back by this opening into the steam-boiler; for the hot steam being suddenly condensed on coming into contact with the cold liquid, a vacuum will necessarily be formed in the end of the tube; into which vacuum the liquid in the vessel—pressed by the whole weight of the incumbent atmosphere—will rush with great force, and with a loud-noise; but if this tube be placed in a vertical position, and if it be made to rise to the height of six or seven feet, the liquid which is thus

forced into its tower end will not have time to rise to that height before it will be met by steam, and obliged to return back into the vessel.—There will be no difficulty in arranging the apparatus in such a manner as effectually to prevent the liquid to be heated from being forced backwards into the steam boiler; and, when this is done, and some other necessary precautions to prevent accidents are taken, steam may be employed with great advantage for heating liquids; and for keeping them hot, in a variety of cases, in which fire, applied immediately to the bottoms of the containing vessels, is now used.

"In dyeing, for instance, and in brewing, and in the processes of many other arts and manufactures, the adoption of this method of applying heat would be attended not only with a great saving of labour and of fuel, but also of a considerable saving of expence in the purchase and repairs of boilers, and of other expensive machinery: for when steam is used instead of fire for heating their contents, boilers may be made extremely thin and light; and, as they may easily be supported and strengthened by hoops and braces of iron, and other cheap materials, they will cost but little, and seldom stand in need of repairs. To these advantages we may add others of still greater importance: boilers intended to be heated in this manner may, without the smallest difficulty, be placed in any part of a room, at any distance from the fire, and in situations in which they may be approached freely on every side. They may moreover easily be so surrounded with wood, or with other cheap substances, which form warm covering, as most completely to confine the heat within them, and prevent its escape. The tubes by which the steam is brought from the principal boiler (which tubes may conveniently be suspended just below the ceiling of the room) may, in like manner, be covered, so as almost entirely to prevent all loss of heat by the surfaces of them; and this to whatever distances they be made to extend.

"In suspending these steam-tubes, care must, however, be taken to lay them in a situation *not perfectly horizontal* under the ceiling, but to incline them at a small angle, making them rise gradually from their junction with the top of a large vertical steam-tube, connecting them with the steam-boiler, quite to their furthest extremities: for, when these tubes are so placed, it is evident that all the water formed in them, in consequence of the condensation of the steam in its passage through them, will run backwards, and fall into the boiler, instead of accumulating in them, and obstructing the passage of the steam, which it would not fail to do were there any considerable bends or wavings, upwards and downwards, in these tubes; or of running forward, and descending with the steam into the vessels containing the liquids to be heated, which would happen if these tubes inclined downwards instead of inclining upwards, as they recede from the boiler.

"In order that clear and distinct ideas may be formed of the various parts of this apparatus, even without figures, I shall distinguish each part by a specific name: the vessel in which water is boiled in order to generate steam, and which, in its construction, may be made to resemble the boiler of a steam-engine, I shall call the *steam-boiler*: the vertical tube, which, rising up from the top of the boiler, conveys the steam into the tubes (nearly horizontal) which are suspended from the ceiling of the room, I shall call the *prime-conductor*: to the horizontal tubes I shall give the name of *horizontal con-*

* Although one should naturally imagine that the notoriety of these facts would have been sufficient to prevent all attempts in our days to claim a right to this invention, yet it is said that a patent for it was taken out only a few years ago.

ductors, or simply *conductors of steam*: and to the (smaller) tubes, which, descending perpendicularly from these *horizontal conductors*, convey the steam to the liquids which are to be heated, I shall, exclusively, appropriate the appellation of *steam-tubes*.

"The vessels in which the liquids are put that are to be heated I shall call the *containing vessels*.—These vessels may be made of any form; and, in many cases, they may, without any inconvenience, be constructed of wood, or of other cheap materials, instead of being made of costly metals, by which means a very heavy expence may be avoided.

"Each *steam tube* must descend perpendicularly from the *horizontal conductor* with which it is connected to the level of the bottom of the *containing vessel* to which it belongs; and, moreover, must be furnished with a good brass cock, perfectly steam-tight; which may be best placed at the height of about six feet above the level of the floor of the room.

"This *steam tube* may either descend *within the vessel* to which it belongs, or *on the outside of it*, as shall be found most convenient. If it comes down on the outside of the vessel; it must enter it at its bottom, by a short horizontal bend; and its junction with the bottom of the vessel must be well secured, to prevent leakage. If it comes down into the vessel, on the inside of it, it must descend to the bottom of it, or at least to within a very few inches of the bottom of it; otherwise the liquid in the vessel will not be uniformly and equally heated.

"When the *steam tube* is brought down on the inside of the containing vessel, it may either come down perpendicularly, and without touching the sides of it, or it may come down on one side of the vessel, and in contact with it.

"When several *steam tubes*, belonging to different containing vessels, are connected with one and the same horizontal *steam conductor*, the upper end of each of these tubes, instead of being simply attached by soldering to the under side of the conductor, must enter at least one inch within the cavity of it; otherwise the water resulting from a condensation of a part of the steam in the conductor, by the cold air which surrounds it, instead of finding its way back into the steam boiler, will descend through the steam tubes and mix with the liquids in the vessels below; but when the open ends of these tubes project upwards within the steam conductor, though it be but to a small height above the level of its under side, it is evident that this accident cannot happen.

"It is not necessary to observe here, that, in order that the ends of the steam tubes may project within the *horizontal conductor*, the diameters of the former must be considerably less than the diameter of the latter.

"To prevent the loss of heat arising from the cooling of the different tubes through which the steam must pass in coming from the boiler, all those tubes should be well defended from the cold air of the atmosphere, by means of warm covering; but this may easily be done, and at a very trifling expence. The horizontal conductors may be enclosed within square wooden tubes, and surrounded on every side by charcoal dust,—fine saw-dust,—or even by wool;—and the steam tubes, and prime conductor, may be surrounded, first by three or four coatings of strong paper, firmly attached to them by paste or glue, and covered with a coating of varnish, and then by a covering of thick coarse cloth. It will likewise be advisable to cover the horizontal conductor with several coatings of paper; for if the paper be put on to them while it is wet with the paste or glue, and if care be taken to put it on in long slips or bands, wound regularly round the tube in a spiral line, from one end of it to the other, this covering

will be useful, not only by confining more effectually the heat, but also by adding very much to the strength of the tube, and rendering it unnecessary to employ thick and strong sheets of metal in the construction of it.

"However extraordinary and incredible it may appear, I can assert it as a fact, which I have proved by repeated experiments, that if a hollow tube, constructed of sheet copper $\frac{1}{8}$ of an inch in thickness, be covered by a coating only twice as thick, or $\frac{1}{4}$ of an inch in thickness, formed of layers of strong paper, firmly attached to it by good glue, the strength of the tube will be *more than doubled* by this covering. I found by experiments, the most unexceptionable and decisive—of which I intend at some future period to give to the public a full and detailed account,—that the strength of paper is such, when several sheets of it are firmly attached together with glue, that a solid cylinder of this substance, the transverse section of which should amount to only one superficial inch, would sustain a weight of 30,000 lb. avoirdupois, or above 13 tons, suspended to it, without being pulled asunder or broken. The strength of hemp is still much greater, when it is pulled equally, in the direction of the length of its fibres. I found, from the results of my experiments with this substance, that a cylinder of the size above mentioned, composed of the freight fibres of hemp, glued together, would sustain 92,000 lb. without being pulled asunder.

"A cylinder, of equal dimensions, composed of the strongest iron I could ever meet with, would not sustain more than 66,000 lb. weight; and the iron must be very good not to be pulled asunder with a weight equal to 55,000 lb. avoirdupois.

"I shall not, in this place, enlarge on the many advantages that may be derived from a knowledge of these curious facts. I have mentioned them now in order that they may be known to the public; and that ingenious men, who have leisure for these researches, may be induced to turn their attention to a subject, not only very interesting, on many accounts, but which promises to lead to most important improvements in mechanics.

"I cannot return from this digression without just mentioning one or two results of my experimental investigations relative to the force of cohesion, or strength of bodies, which certainly are well calculated to excite the curiosity of men of science.

"The strength of bodies of different sizes, *similar in form*, and composed of the *same substance*,—or the forces by which they resist being pulled asunder by weights suspended to them, and acting in the direction of their lengths, are *not in the simple ratio of the areas of their transverse sections*, or of their *fractures*;—but in a higher ratio;—and this ratio is different in different substances.

"The form of a body has a considerable influence on its strength, *even when it is pulled in the direction of its length*.

"All bodies; even the most brittle, appear to be *torn asunder*, or their particles separated, or fibres broken, *one after the other*; and hence it is evident, that that *form* must be most favourable to the strength of any given body, pulled in the direction of its length, which enables the greatest number of its particles, or longitudinal fibres, to be separated to the greatest possible distance—short of that at which the force of cohesion is overcome,—before any of them have been forced beyond that limit.

"It is more than probable that the apparent strength of different substances depends much more on the number of their particles that come into action before any of them are forced beyond the limits of the attraction of cohesion, than on any specific difference in the intensity of that force in those substances.

"But to return to the subject more immediately under consideration.—As it is essential that the steam employed in heating liquids, in the manner before described, should enter the containing vessel at, or very near, its bottom, it is evident that this steam must be sufficiently strong, or elastic, to overcome, not only the pressure of the atmosphere here, but also the additional pressure of the superincumbent liquid in the vessel; the steam boiler must, therefore, be made strong enough to confine the steam, when its elasticity is so much increased by means of additional heat, as to enable it to overcome that resistance. This increase of the elastic force of the steam need not, however, in any case, exceed a pressure of five or six pounds upon a square inch of the boiler, or *one third part*, or *one half*, of an atmosphere.

"It is not necessary for me to observe here, that in this and also in all other cases, where steam is used as a vehicle for conveying heat from one place to another, it is indispensably necessary to provide *safety valves* of two kinds;—the one for letting a part of the steam escape, when, on the fire being suddenly increased, the steam becomes so strong as to expose the boiler to the danger of being burst by it;—the other for admitting air into the boiler, when, in consequence of the diminution of the heat, the steam in the boiler is condensed, and a vacuum is formed in it; and when, without this valve, there would be danger, either of having the sides of the boiler crushed, and forced inwards by the pressure of the atmosphere from without; or of having the liquid in the containing vessels forced upwards into the horizontal steam conductors, and from thence into the steam boiler. This last-mentioned accident, however, cannot happen, unless the cocks in some of the steam tubes happen to be open. The two valves effectually prevent all accidents.

"The reader will, no doubt, be more disposed to pay attention to what has here been advanced, on this interesting subject, when he is informed that the proposed scheme has already been executed on a very large scale, and with complete success; and that the above details are little more than exact descriptions of what actually exists.

"A great mercantile and manufacturing house at Leeds, that of Messrs. Gott and Company, had the courage, notwithstanding the mortifying prediction of all their neighbours, and the ridicule with which the scheme was attempted to be treated, to erect a *dyeing-house*, on a very large scale indeed, on the principles here described and recommended.

"On my visit to Leeds the last summer, I waited on Mr. Gott, who was then mayor of the town, and who received me with great politeness, and shewed me the cloth halls, and other curiosities of the place; but nothing he shewed me interested me half so much as his own truly noble manufactory of superfine woollen cloths. I had seen few manufactories so extensive, and none so complete in all its parts. It was burnt to the ground the year before I saw it, and had just been rebuilt on a larger scale; and with great improvements in almost every one of its details. The reader may easily conceive, that I felt no small degree of satisfaction on going into the dyeing-house, to find it fitted up on principles which I had some share in bringing into repute, and which Mr. Gott told me he had adopted in consequence of the information he had acquired in the perusal of my *seventh* essay. He assured me that the experiment had answered, even far beyond his most sanguine expectations; and, as a strong proof of the utility of the plan, he told me, that his next-door neighbour, who is a dyer by profession, and who, at first, was strongly prejudiced against these innovations, has lately adopted them, and is now convinced that they are real improvements. Mr. Gott assured me that he

had no doubt but that they would be adopted by every dyer in Great Britain in the course of a very few years.

"The dyeing-house of Messrs. Gott and Company, which is situated on the ground-floor of the principal building of the manufactory, is very spacious, and contains a great number of coppers of different sizes; and as these vessels, some of which are very large, are distributed about promiscuously, and apparently without any order in their arrangement, in two spacious rooms,—each copper appearing to be insulated, and to have no connection whatever with the others,—all of them together form a singular appearance. The rooms are paved with flat stones, and the brims of all the coppers—great and small—are placed at the same height—about three feet above the pavement: some of these coppers contain upwards of 1800 gallons; and they are all heated by steam from one steam boiler, which is situated in a corner of one of the rooms.

"The horizontal tubes which serve to conduct the steam from the boilers to the coppers are suspended just below the ceiling of the rooms: they are made—some of lead—and some of cast-iron; and are from four to five inches in diameter; but when I saw them, they were naked, or without any covering to confine the heat. On my observing to Mr. Gott that covering for them would be useful, he told me that it was intended that they should be covered, and that coverings would be provided for them.

"The vertical *steam tubes*, by which the steam passes down from the horizontal *steam conductors* into the coppers, are all constructed of lead, and are from $\frac{1}{2}$ of an inch to $\frac{1}{4}$ inches in diameter; being made larger or smaller, according to the sizes of the coppers to which they belong. These steam tubes all pass down on the *outside* of their coppers, and enter them horizontally at the level of their bottoms. Each copper is furnished with a brass cock, for letting off its contents; and it is filled with water from a cistern at a distance, which is brought to it by a leaden pipe. The coppers are all surrounded by thin circular brick walls, which serve not only to support the coppers, but also to confine the heat.

"The rapidity with which these coppers may be heated, by means of steam, is truly astonishing. Mr. Gott assured me that one of the largest of them, containing upwards of 1800 gallons, when filled with cold water from the cistern, requires no more than *half an hour* to heat it till it actually boils!—By the greatest fire that could be made under such a copper, with coals, it would hardly be possible to make it boil in less than an hour.

"It is easy to perceive, that the *saving of time* which will result from the adoption of this new mode of applying heat will be very great;—and it is likewise evident, that it may be increased, almost without limitation, merely by augmenting the diameter of the steam tube: care must, however, be taken that the boiler be sufficiently large to furnish the quantities of steam required.—The *saving of fuel* will also be very considerable: Mr. Gott informed me, that, from the best calculation he had been able to make, it would amount to near two-thirds of the quantity formerly expended, when each copper was heated by a separate fire.

"But these savings are far from being the only advantages that will be derived from the introduction of these improvements in the management of heat: there is one, of great importance indeed—not yet mentioned—which alone would be sufficient to recommend the very general adoption of them.—As the heat communicated by steam can never exceed the mean temperature of boiling water by more than a very few degrees, the substances exposed to it can never be injured by it. In many arts and manufactures this circumstance will be

productive of great advantages, but in none will its utility be more apparent than in cookery; and especially in public kitchens,—where great quantities of food are prepared in large boilers; for, when the heat is conveyed in this manner, all the labour now employed in stirring about the contents of those boilers, to prevent the victuals from being spoiled by the burning to the bottoms of them, will be unnecessary; and the loss of heat occasioned by this stirring prevented; and, instead of expensive coppers, or metallic boilers, which are difficult to be kept clean, and often stand in need of repairs—common wooden tubs may, with great advantage, be used as culinary vessels; and their contents may be heated by *portable fire-places*, by means of steam boilers attached to them.

“As these portable fire-places and their steam boilers may, without the smallest inconvenience, be made of such weight, form, and dimensions, as to be easily transported from one place to another by two men, and be carried through a doorway of the common width—with this machinery, and the steam tubes belonging to it, and a few wooden tubs—a complete public kitchen, for supplying the poor and others with soups, and also with puddings, vegetables, meat, and all other kinds of food prepared by *boiling*, might be established in half an hour, in any room, in which there is a chimney (by which the smoke from the portable fire-place can be carried off); and, when the room should be no longer wanted as a kitchen, it might, in a few minutes, be cleared of all this culinary apparatus, and made ready to be used for any other purpose.

“This method of conveying heat is peculiarly well adapted for heating baths: it is likewise highly probable that it would be found useful in the bleaching business, and in washing linen. It would also be very useful in all cases where it is required to keep any liquid at about the boiling point for a long time without making it boil; for the quantity of heat admitted may be very nicely regulated by means of the brass cock belonging to the steam tube. Mr. Gott shewed me a boiler in which shreds of skins were digesting in order to make glue, which was heated in this manner; and in which the heat was so regulated, that, although the liquid never actually boiled, it always appeared to be upon the very point of beginning to boil.

“This temperature had been found to be best calculated for making good glue. Had any other *lower* temperature been found to answer better, it might have been kept up with the same ease, and with equal precision, by regulating properly the quantity of steam admitted.

“I need not say how much this country is obliged to Mr. Gott, and his worthy colleagues.—To the spirited exertions of such men—who abound in no other country—we owe one of the proudest distinctions of our national character;—that of being an *enlightened and an enterprising people*.”

For the method of applying heat by steam in houses, &c. see the articles *HOT-HOUSE* and *HOT-BED* in this SUPPLEMENT.

HEBRON, a town of Palestine, situated partly on a hill and partly on a plain. The Christians have a church here, which they say contains the tombs of Abraham and Sarah, to which the Mahometans, as well as Christians, come in pilgrimage. The valley or plain of Maure is not far from Hebron; it is fertile, and planted with excellent vineyards. Constantine built a church here, the walls of which are yet in existence: eight leagues S.W. Jerusalem.

HECHINGEN, a town of Germany, in the circle of Swabia, which gives name to a branch of the family of Hohenzollern, and is the residence of the prince; 30 miles S. Stuttgart, and 52 E.S.E. Stralsburg.

HEDEMORA, a town of Sweden, in the province of Dalecarlia, and one of the principal towns of the kingdom, situated near a lake, well built and commercial. Here is a large manufacture of gunpowder: 53 miles N.W. Upfal. Long. 16. E. Greenwich. Lat. 60. 17. N.

HEDGE (*Encycl.*). The late Mr. Bakewell was remarkably curious in his fences: he used to plant one row at the distance of a foot from set to set; and, after making the ditch, to lay the earth dug out of it, so as to form a bank on the side opposite to the quick. In other parts of England, the bank is made on the side of the quick above it. The advantage of Mr. B.'s method is, that the plants grow only in the *surface-earth*, not secluded from the atmosphere; whereas, in the common practice, the best earth is generally loaded by a thick covering of mud taken from the ditch, and placed obliquely on the bank. There is, however, a considerable waste of land in the former method: for, after the whole was thus formed, he usually added a double post and rail; one on the outside of such bank, and the other on the outside of the quick.

Hedges designed for ornament in gardens, are sometimes planted with evergreens, among which the holly is preferable to any other; next in rank is the yew, but the dead colour of its leaves renders such hedges less agreeable. The laurel is another plant that may be employed as a fence for gardens; as it is one of the most beautiful evergreens; but it shoots forth with such luxuriance, that it is very difficult to confine it to any shape: its leaves, too, are very large, and, if cut through with the sheers, present a very disagreeable appearance: hence they ought to be pruned with a knife, and the shoots exactly cut down to each leaf.

In the 3d vol. of the *Transactions of the Society for the Encouragement of Arts*, &c. Mr. Leatham, of Barton, gives an account of his method of planting quickset hedges on dry, gravelly, or thin soils. He considers the causes which render such hedges very indifferent, to be—1. That they are set too low or flat on the surface, to allow the roots to strike deeply into the soil. 2. That, when planted higher, they are generally too near the slope of the bank, and thus cannot receive the benefit of the rain. To remedy these inconveniences, two lines are marked out, 12 feet apart; the upper part of the soil is taken from three feet within each line, and thrown into the centre of the space, so as to form a flat bed, three feet in breadth, in the midst of which the quicks are planted; the remaining space of 18 inches on each side is filled up with the earth, gravel, or sand taken out of the ditches on both sides, by which means the bed is extended to five feet, allowing six inches for the slope of the bank. Quicks, thus planted, will find sufficient nourishment in the soil, before the tap-root reaches the barren gravelly bottom; and the earth thus placed, will retain moisture enough to nourish the plants; so that they will in a short time form an excellent fence, which, by elevating the bank on each side at pleasure, may be protected at a small expence from the ill effects of sharp winds, or the air of the sea. Mr. Leatham observes, that the space, on such low-priced ground, is but small; and, as a good thriving fence is obtained, it amply compensates the expences. A hedge, constructed according to the dimensions above stated, cost him fifteen pence per rod of seventy yards in length.

In the 1st vol. of the *Letters and Papers of the Bath and W'est of England Society*, we meet with a communication, in which *elms* are recommended for fences. When elm-timber is felled in the spring, the chips made in trimming the trees are to be sown on a piece of newly-ploughed land, and harrowed in, as is practised with corn. Every chip, that has an

eye or bud, will speedily shoot like the cuttings of potatoes; and, as such plants have no tap-roots, but strike their fibres horizontally in the richest part of the soil, they will be more vigorous, and may be more easily transplanted, than if they had been raised from seeds, or in any other manner. They possess this further advantage, that five or six stems will generally rise from the same chip; and, after being cut down to within three inches of the ground, they will multiply their side-shoots in proportion, and form a thicker hedge, without running to naked wood, than by any other method hitherto practised. Lastly, if they be kept carefully clipped for the first three or four years, they are said to become almost impenetrable.

In the second volume of the same instructive work, we find another communication on the subject of hedges; and the great advantages that might be derived from them, by planting cyder-fruit-trees. If a judicious mixture of such trees were set in hedges, the profit they afford would amply compensate the expences incurred, without any loss of ground. And, as the best kinds of this fruit are so extremely four at the proper season of gathering, that even hogs will scarcely touch them, depredations are not to be apprehended.

Having already treated on FRANCES, we shall only add, that those of our readers who wish to acquire a more complete information on the subject, may with advantage peruse the first and second volumes of Dr. Anderson's *Essays on Agriculture*, in which it is fully discussed, and the plants best calculated for making hedges are judiciously pointed out.

HEILIGE-LAND, an island of the German Ocean, between the mouths of the Eyder and the Elbe. It belongs to the king of Denmark. Long. 8. 20. E. Lat. 54. 21. N.

HEILIGENBERG, a town of Germany, in the archduchy of Austria: 1 mile N. Rotz.

HEILIGENSTADT, a town of Germany, capital of the territory of Etchfel, belonging to the elector of Mentz. It is seated at the confluence of the Geitland and Leina, 30 miles N.W. of Eisenach. Long. 10. 14. E. Lat. 51. 22. N.

HEILSBRUNN, a town of Franconia, in the principality of Anspach, with a medical spring, 10 miles E.N.E. of Anspach, and 16. S.W. of Nuremberg.

HEIRSHIP MOVEABLES, in Scots law, the best of certain kinds of moveables, which the heir of line is entitled to take, besides the heritable estate.

HELL-GATE, a celebrated strait near the W. end of Long Island Sound, eight miles E. of New York. It is remarkable for its whirlpools, which are occasioned by the narrowness and crookedness of the pass, and a bed of rocks extending quite across; but, at proper times of the tide, a skilful pilot may conduct a ship of any burthen through this strait.

HELMERSHAUSEN, a town of Germany, in the principality of Hesse-Cassel, 19 miles W. of Göttingen, and 22 N. of Cassel. Long. 9. 32. E. Lat. 51. 32. N.

HELMONT, a town of Dutch Brabant, with a strong castle, seated on the Aa, 17 miles S.E. of Bois-le-Duc. Long. 5. 37. E. Lat. 51. 31. N.

HELZSTADT, a town of Upper Saxony, in the county of Mansfeld, 9 miles N. of Eisleben, and 16. S.E. of Quedlinburg. Long. 12. 14. E. Lat. 51. 47. N.

HEMATH, or HAMATH (anc. geog.), the name of a city (whose king was David's friend, 2 Sam. ix.) to the south of Lebanon; from which a territory was called *Nemath*, on the north of Canaan and south of Syria, as appears by the spies, Numb. xiii. 1 Kings viii. Ezek. xlvii. Whether one or more cities and districts of this name lay in this tract, neither interpreters nor geographers are agreed. The eastern part was called *Hemath-zoba*, 2 Chron. viii. unless we suppose that there was a city in *Zoba* of this name fortified by

Solomon. In defining the boundary of Palestine, it is often said, *from the entering of Hamath*; as a province to be entered into through a fruit or defile. And if there was such, the next question is, from what metropolis it was called *Hemath*? Antioch, capital of Syria, is supposed to be called *Hemath* or *Amutha* (Jonathan, Targum; &c.); and again *Epiphania*, (Josephus). Both were to the north of Lebanon; consequently not the *Hemath* of Scripture, the immediate boundary of Palestine to the north, and lying to the south of Lebanon.

HEMMENDORF, a town of Lower Saxony, in the principality of Calenberg, situate on the Saale, 12 miles E. of Hamelin.

HENRY IV. emperor of Germany in 1056, styled *the Great*, was memorable for his quarrels with Pope Gregory II. whom at one time he deposed, for having presumed to judge his sovereign; but at another, dreading the effects of the papal anathemas, he had the weakness to submit to the most humiliating personal solicitations and penances to obtain absolution, which impolitic measure increased the power of the pope, and alienated the affections of his subjects: thus circumstanced, he re-assumed the hero, but too late; marched with an army to Rome, expelled Gregory, deposed him, and set up another pope. Gregory died soon after: but Urban II. and Pascal II. successively excited his ambitious sons, Conrad and Henry, to rebel against him, and the latter was crowned emperor by the title of Henry V. in 1106; and he had the inhumanity to arrest his father, and to deprive him, not only of all his dignities, but even of the necessaries of life. The unfortunate Henry IV. was reduced to such extremities (after having fought 62 battles in defence of the German empire), that he solicited the Bishop of Spire to grant him an underground place in his cathedral, but was refused. He died the same year, at Liege, aged 55, a martyr to the ignorance and superstition of the age, and to his own blind confidence in favourites and mistresses.

HENRY IV. king of France (in 1589) and Navarre, justly styled *the Great*, was the son of Anthony de Bourbon, chief of the branch of Bourbon (so called from a fief of that name which fell to them by marriage with the heiress of the estate). His mother was the daughter of Henry de Albert, king of Navarre; a woman of a masculine genius; intrepid, simple, and rustic in her manners, but deeply versed in politics, and a zealous protestant. Foreseeing that her party would want such a protector (for her husband was a weak indolent prince), she undertook the care of the education of the young hero: his diet was coarse; his clothes neat, but plain; he always went bare-headed; the sent him to school with the other children of the same age, and accustomed him to climb the rocks and neighbouring mountains, according to the custom of the country. He was born in 1553; and in 1569, the 16th year of his age, he was declared the Defender and Chief of the Protestants at Rochelle. The peace of St. Germain, concluded in 1570, recalled the lords in the Protestant interest to court; and in 1572 Henry was married to Margaret de Valois, sister to Charles IX. king of France. It was in the midst of the rejoicings for these nuptials, that the horrid massacre of Paris took place. Henry was reduced, by this infernal stroke of false policy, to the alternative of changing his religion or being put to death: he chose the former, and was detained prisoner of state three years. In 1587 he made his escape; put himself at the head of the Huguenot party, exposing himself to all risks and fatigues of a religious war, and enduring all the hardships of the common soldier: but he gained a victory this year at Courtras, which established his reputation in arms, and endeared him to the Protestants. On the death of Henry III. religion was urged as a pretext for

one half of the officers of the French army to reject him, and for the leaguers not to acknowledge him. A phantom, the Cardinal de Bourbon, was set up against him; but his most formidable rival was the Duke de Mayenne: however, Henry, with few friends, fewer important places, no money, and a very small army, supplied every want by his activity and valour. He gained several victories over the duke; particularly that of Ivry in 1599, memorable for his heroic admonition to his soldiers: "If you love your ensigns, rally by my white plume, you will always find it in the road to honour and glory." Paris held out against him, notwithstanding his successes: he took all the suburbs in one day; and might have reduced the city by famine, if he had not humanely suffered his own army to relieve the besieged: yet the bigotted friars and priests in Paris all turned soldiers, except four of the Mendicant order; and made daily military reviews and processions, the sword in one hand and the crucifix in the other, on which they made the citizens swear rather to die with famine than to admit Henry. The scarcity of provisions in Paris at last degenerated to an universal famine; bread had been sold, whilst any remained, for a crown the pound, and at last it was made from the bones of the charnel-house of St. Innocents: human flesh became the food of the obdurate Parisians, and mothers ate the dead bodies of their children. In fine, the Duke of Mayenne, seeing that neither Spain nor the league would ever grant him the crown, determined to assist in giving it to the lawful heir. He engaged the states to hold a conference with the chiefs of both parties; which ended in Henry's abjuration of the Protestant religion at St. Denis, and his consecration at Chartres in 1593. The following year Paris opened its gates to him; in 1596, the Duke of Mayenne was pardoned; and in 1598, peace was concluded with Spain. Henry now shewed himself doubly worthy of the throne, by his encouragement of commerce, the fine arts, and manufactures, and by his patronage of men of ingenuity and sound learning of every country; but though the fermentations of Romish bigotry were calmed, the heaven was not destroyed; scarce a year passed without some attempt being made on this real father of his people; and at last the monster Ravallac stabbed him to the heart in his coach, in the streets of Paris, on the 14th of May, 1610, in the 57th year of his age, and 22d of his reign.

HENRY, of Huntingdon, an English historian, of the 12th century, was canon of Lincoln, and afterwards archdeacon of Huntingdon. He wrote, 1. A History of England, which ends with the year 1154. 2. A continuation of that of Bede. 3. Chronological tables of the kings of England. 4. A small treatise on the contempt of the world. 5. Several books of epigrams and love-verses. - 6. A poem on herbs: all which are written in Latin. - His invocation of Apollo and the goddesses of Tempe, in the exordium of his poem on herbs, may not be unacceptable as a specimen of his poetry:

Vatum magne parens, herbarum Phoebe reperto.
Vosque, quibus resonant Tempe iocosa Deae!
Si mihi ferta prius hederæ florente paratis,
Ecce meos flores, ferta parate fero.

HENRY, of Susa, in Latin *de Segusio*, a famous civilian and canonist of the 13th century, acquired such reputation by his learning, that he was called the *source and splendor of the law*. He was archbishop of Embrun about the year 1258, and cardinal bishop of Ostia in 1262. He wrote *A summary of the canon and civil law*; and *A commentary on the book of the decretals*, composed by order of Alexander IV.

HENRY (Matthew), an eminent dissenting minister and

author, was the son of Philip Henry, a nonconformist minister, and was born in the year 1662. He continued under his father's care till he was 18 years of age; in which time he became well skilled in the learned languages, especially in the Hebrew, which his father had rendered familiar to him from his childhood; and from first to last the study of the scriptures was his most delightful employment. He completed his education in an academy kept at Ilidngton by Mr. Doolittle, and was afterwards entered in Gray's Inn for the study of the law; where he became well acquainted with the civil and municipal law of his own country, and from his application and great abilities it was thought he would have become very eminent in that profession. But at length, resolving to devote his life to the study of divinity, in 1686 he retired into the country, and was chosen pastor of a congregation at Chester, where he lived about 25 years, greatly esteemed and beloved by his people. He had several calls from London, which he constantly declined; but was at last prevailed upon to accept an unanimous invitation from a congregation at Hackney. He wrote, 1. *Expositions of the Bible*, in 5 vols. folio. 2. *The Life of Mr. Philip Henry*. 3. *Directions for daily Communion with God*. 4. *A Method for Prayer*. - 5. *Four Discourses against Vice and Immorality*. 6. *The Communicant's Companion*. 7. *Family Hymns*. 8. *A Scriptural Catechism*; and, 9. *A Discourse concerning the Nature of Schism*. He died of an apoplexy at Nantwich, when upon a journey, in 1714; and was interred at Trinity-church, in Chester.

HEPPENHEIM, a town of Germany, in the electorate of Mentz, with a castle and an abbey; seated between Heidelberg and Darmstadt, about 14 miles from each. Long. 8. 41. E. Lat. 49. 29. N.

HERAT, a town of Persia, in the province of Korafan, 160 miles S. E. of Mechid. Long. 61. 0. E. Lat. 34. 30. N.

HERAULT, one of the 83 departments of France, so named from a river which falls into the gulf of Lyons. It includes part of the late province of Languedoc: and the capital of Montpellier.

HERBEMONT, a town of the Austrian Netherlands, in the duchy of Luxemburg, with a castle seated on a mountain, near the river Semoy, three miles from Chiny.

HERBAL (*Encycl.*). Among the different methods adopted by botanists, for obtaining a *HORTUS SICCUS*, the following appear to be the most practicable:

1. Lay the plants flat between papers; then place them between two smooth plates of iron screwed together at the corners: in this state they are to be committed to a baker's oven for two hours. After being taken out, they must be rubbed over with a mixture consisting of equal parts of brandy and vinegar, then passed down on paper with a solution of gum-tragacanth in water, after which they are to be laid in a book, where they will adhere, and retain their original freshness. - Although this process was suggested by Sir R. Southwell, in the 237th Number of the *Philosophical Transactions of the Royal Society*, yet the following method is more simple:

2. Flatten the plant, by passing a common smoothing iron over the papers between which it is placed; and dry it slowly in a sand-heat. For this purpose, the cold sand ought to be spread evenly, the smoothed plant laid gently on it, and sand sifted over so as to form a thick bed; the fire is then to be kindled, and the whole process carefully watched, till the plant is gradually and perfectly dried. - Thus, the colour of the tenderest herb may be preserved, and the most delicate flowers retain all their pristine beauty.

3. Another, and far more complete method, was suggested by the ingenious Mr. Whately; and bears a slight resemblance

to that last specified. He directs those who intend to follow his plan, previously to procure—1. A strong oak-box of the same size and shape as those employed for packing up tin plates; 2. A quantity of fine sifted sand, sufficient to fill the box; 3. A considerable number of pieces of plant paper, from one to four inches square; and, 4. Some small flat leaden weights, and a few small, bound books.

He then directs the specimen of the plant intended for the herbal to be gathered, when dry and in full bloom, with all its parts as perfect as possible, and conveyed home in a tin box, well secluded from the air. The plant is first to be cleared from the soil as well as the decayed leaves, and then laid on the inside of one of the leaves of a sheet of common cap-paper. The upper leaves and flowers are next to be covered, when expanded, by pieces of the prepared paper, and one or two of the leaden weights placed on them. The remainder of the plant is now to be treated in a similar manner.

The weights ought next to be gently removed, and the other leaf of the sheet of paper folded over the opposite one, so as to contain the loose pieces of paper and plants between them. A book or two is now to be applied to the outside of the paper, till the intended number of plants is thus prepared; when a box is to be filled with sand to the depth of an inch, one of the plants put in, and covered with sand sufficient to prevent the form of the plant from varying. The other plants may then be placed in succession, and likewise covered with a layer of sand, one inch thick between each; after which the whole is to be gently pressed down in a greater or less degree, according to the tenderness or firmness of the plants.

The box is next to be carefully placed before a fire, one side being occasionally a little raised, as may be most convenient; the sides being alternately presented to the fire, two or three times in the day; or, the whole may be put into an oven gently heated. In the course of two or three days, the plants will be perfectly dry, when the sand ought to be taken out, and put into another box: the plants should likewise be removed to a sheet of writing paper.

This method of preserving plants, Mr. Whately states to be preferable to every other, as both the flowers and leaves, if kept loosely within the paper, in a dry room, without being exposed to the air, will retain their beauty for several years. It will, however, be necessary to inspect them once in the course of a year, for the purpose of destroying any small insects, that may accidentally breed among the plants.

HERBORN, a town of Germany, in the circle of the Upper Rhine and territory of Naïssau, with a famous university and woollen manufacture; 8 miles S.W. of Dillenburg. Long. 8. 20. E. Lat. 50. 40. N.

HERETABLE RIGHTS, in Scots law, all rights affecting lands, houses, &c. or any immovable subject.

HERETAGE, in Scots law, lands, houses, or any immovable subject, in contradistinction to moveables or moveable subjects. It also sometimes signifies such immovable property as a person succeeds to as heir to another, in contradistinction to that which he himself purchases or acquires in any other manner, called *conquest*.

HERICOUR, a town of France, in the department of Upper Saône, 11 miles S.E. of Lure, and 23 E. of Vesoul. Long. 6. 28. E. Lat. 47. 34. N.

HERMBACH, a town of Westphalia, in the duchy of Juliers, 17 miles S. of Juliers. Long. 6. 20. E. Lat. 50. 42. N.

HERMUS (*Encycl.*). Erroneously spelt **HERMES**.

HERNHUT, a famous place in Upper Lusatia, in the territory of the elector of Saxony, between Zittaw and Loebau.

Here, in 1722, some persecuted Moravian brethren (descendants of the church of the ancient United Brethren, established in Bohemia and Moravia, as early as the year 1456) settled in the fields of the village of Betheldorf, belonging to count Zinzendorf, and began to build another village. They were joined by some Protestants, who had been bred in other societies. They all agreed in adopting the confession of Augsburg, and lived as brethren, without quarrelling about particular sentiments; and when, after some time, the number of those admitted from other Protestant churches, became greater than the number of the Moravian brethren, they took the name of Evangelical Brethren, or the Brethren's Unity of the Augsburg Confession. They considered Count Zinzendorf as their bishop and father, and were, for some time, called *Hernhutters*, as this place continued their principal nursery. There were afterward extended into many different countries; were introduced into America, in 1741, by Count Zinzendorf, and settled at Bethlehem in Pennsylvania. Their societies, which are now numerous in that country, afford the most pleasing examples of piety and virtue. See **BETHLEHEM**, **LITIZ**, and **NAZARETH**.

HEROD, falsely styled *the Great*, king and execrable tyrant of Judæa; who, on the strength of a misinterpreted prophecy, caused all the male children of Bethlehem and its neighbourhood to be massacred by his soldiers at the time of the birth of Christ, in the vain hope of destroying the Saviour of mankind. He died, eaten with worms, two or three years after the birth of our Saviour, at the age of 71, after a reign of 40 years. He had ordered that all the persons of quality, whom he kept in prison, should be massacred the moment the breath was out of his body, in order that every considerable family in the kingdom might shed tears at his death; but that inhuman order was not executed.

HEROLDSBERG, a town of Franconia, in the territory of Nuremberg, 7 miles N.N.E. of Nuremberg.

HERRIEDEN, a town of Franconia, in the bishopric of Aichstet, situate on the Altmuhl, 5 miles S.W. of Anspach. Long. 10. 40. E. Lat. 49. 10. N.

HERSTAL, a town of Germany, in the bishopric of Liege, with an ancient castle, seated on the Maese, 3 miles N. of Liege. Long. 5. 40. E. Lat. 50. 40. N.

HERZEGOVINA, a fortified town of Turkish Dalmatia, capital of a duchy of the same name, and the residence of a Turkish governor. It is 80 miles S.S.W. of Belgrade.

HEURNIUS, or **VAN HEURN** (John), a learned physician, was born at Utrecht, in 1543; and studied at Louvain, Paris, Padua, and Pavia. At his return to his native country he became magistrate of Amsterdam; after which he was professor of physic at Leyden, and rector of the university of that city, where he died in 1601. He wrote, among other works, several treatises on the diseases of different parts of the body, and several commentaries on the works of Hippocrates. *Otho Heurnius*, his son, was also professor of physic at Leyden, and wrote some books.

HEYLESEM, a town of Austrian Brabant, 14 miles S.E. of Louvain. Long. 5. 7. E. Lat. 50. 45. N.

HEYMERISEN, a town of Germany, in the electorate of Cologne, situate on the Riff, 30 miles E. of Aix la Chapelle. Long. 6. 37. E. Lat. 10. 46. N.

HEYTESBURY, a borough in Wilts, that sends two members to Parliament, but has now no market. It is 20 miles N.W. of Salisbury, and 93 W. by S. of London. Long. 2. 8. W. Lat. 51. 12. N.

HILLIGENHAVEN, a town of Lower Saxony, in the duchy of Holstein, situate on the Baltic, 37 miles N. of Lubec.

HILLSBOROUGH, a town of N. Carolina, 180 miles W. by N. of Newbern.

HINDIA, a town of the Deccan of Hindoostan, capital of a district of the same name, in the county of Candesh. It is situate on the Nerbudda, 90 miles N.N.E. of Burham-pour. Long. 77. 10. E. Lat. 22. 35. N.

HINLOPEN, see **HINDELOPEN**.

HINTERGERSDORF, a town of Upper Saxony, in the circle of Erzgebürg, eight miles E. of Freyburg.

HIORRING, a town of Denmark, in N. Jutland, once the see of a bishop, but the bishopric was removed to Alburg, by Frederic II. It is 27 miles N.N.W. of Alburg. Long. 9. 38. E. Lat. 57. 2. N.

HIRSH-HORN, a town of Germany, in the palatinate of the Rhine, with a castle. It is seated on the side of a hill, on the Neckar, near Eberbach.

HIRSCHOLM, a town of Denmark, in the island of Zealand, 12 miles N. of Copenhagen.

HISSAR, a town of Hindoostan Proper, capital of a district of the same name, in the country of Delhi. It is seated near the river Sursoory, 112 miles W.N.W. of Delhi. Long. 75. 40. E. Lat. 29. 5. N.

HOANG-TCHEOU, a city of China of the first rank, in the province of Hou-quang, on the Yang-tse: 585 miles S. of Peking. Long. 132. 12. E. Ferro. Lat. 38. 28. N.

HOANG-TCHEOU, a town of the kingdom of Corea, in the province of Hoang-hai: eighty-five miles N.N.W. King-ki-tao. Long. 143. 38. E. Ferro. Lat. 38. 42. N.

HOENG (*Encycl.*). Under **HUSBANDRY** we have spoken fully on the practice of hoeing.

In order further to facilitate this important object, we shall present to our readers three hand-hoes, much superior to those in common use, and which, from their simplicity, deserve to be more generally known. See Plate 33. where fig. 1. is the *Portuguese hoe*, lately described and recommended by Lord Somerville.

The handle of this implement is from three feet to three feet four inches in length; and, as it is both light and short, it is peculiarly calculated for strong lands and mountainous situations; because the hoe, by its weight and pointed form, cuts deeply into earth, without requiring much exertion.

Fig. 2. is the *Horse-shoe hoe*, invented by Mr. Mark Duckett, of Esher, Surrey:

This hoe is furnished with a ring or loop, as there represented, near the bottom of the handle, for holding a strap, which is fastened round the waist of the persons at work, as they walk backwards. It is eminently useful for cleaning crops of every description, whether drilled or hand-set in rows. Mr. Duckett has judiciously availed himself of a short handle, and heavy iron-work, the exact reverse of the common hoe, which requires great exertion to make any impression on the soil (excepting on the lightest sands), especially if it has become dry and hard.

It is evident from the engraving, that Mr. Duckett's hoes, by their convex form, earth up as well as down; though the same implement may also be made with *straight* edges; namely, for drilled or dibbled crops at six inches interval; for clearing peas, beans, &c. at 18 inches distance; and for dressing crops of any description, at 12 inches interval.—Should these hoes, however, from their *straight* edge, be unequal to cope with stiff land, Lord Somerville suggests the expediency of adopting the *conical* edge (or the edge opposite to that in the horse-shoe hoe) which will remarkably increase their power. Lastly, his Lordship observes, that *three* flat hoes at six inches; *two* flat ones at twelve inches; and *three* horse-shoe hoes, form the whole number requisite; and that they all crew into the same frame and handle.

HOEI-TCHEOU-FOU, a commercial city of China, in the province of Quanton. Its jurisdiction contains 11 cities

of the second and third class. Long. 113. 58. E. Lat. 23. 1. N.

HOGARTH (*Encycl.*). A handsome monument to the memory of this exemplary artist is to be seen in the church-yard at Chiswick. It consists of a handsome ornamented base bearing an urn upon a smaller pedestal. On the north side is the following inscription:

Farewel, great painter of mankind,
Who reach'd the noblest point of art;
Whose pictur'd morals charm the mind;
And through the eye correct the heart.

If genius fire thee, reader, stay;
If nature touch thee, drop a tear!
If neither move thee, turn away;
For HOGARTH'S honour'd dust lies here.

D. GARRICK.

On the east side,

Here lieth the body
of WILLIAM HOGARTH, Esq.
who died Oct. 26, 1764,
aged 67 years.

HOHENZOLLERN, a town of Suabia, capital of a county of the same name, with a castle. It is seated on a mountain, 28 miles S. of Stuttgart. Long. 9. 6. E. Lat. 48. 24. N.

HOLBECK, a sea-port of Denmark, in the island of Zealand, with a good harbour, from which great quantities of corn are annually exported. In 1290 this town was destroyed by a fleet from Norway. It is 30 miles W. of Copenhagen. Long. 11. 44. E. Lat. 55. 42. N.

HOLSTEBRØE, a town of Denmark, in N. Jutland, situate on a shallow river which runs into the North Sea. Its principal trade is in corn, oxen, and horses. It is 24 miles W. of Wiburg, and 68 N. of Ripen. Long. 9. 25. E. Lat. 56. 20. N.

HOLTZMUNDEN, a town of Lower Saxony, in the principality of Wolfenbüttele, 28 miles N.W. of Göttingen.

HOLZAPFEL, a town of Westphalia, capital of a county of the same name, which gives a seat in the diets. It is situate on the Lahn, at the foot of a mountain, on which is the tower of an ancient castle, the original seat of the princes of Nassau, four miles N.E. of Nassau. Long. 7. 44. E. Lat. 50. 22. N.

HONDISCHOOETE, a town of France, in the department of the North, seven miles S.E. of Dunkirk.

HONEY (*Encycl.*). For a method of extracting sugar from this substance, see **SUGAR**, in this SUPPLEMENT.

HORADAU, a town of Persia, in the province of Farfistan, 76 miles N.W. of Shiras.

HORSE DEALERS. The following duty imposed on horse dealers by stat. 21 Geo. III. c. 31. is repealed, and a new duty charged instead thereof, viz.

By 36 Geo. III. c. 17. every person exercising the trade or business of a horse dealer, must take out a licence from the Stamp Office, for which he shall pay annually, if within London, Westminster, the bills of mortality, the parish of St. Pancras, or the borough of Southwark, 20l. elsewhere 10l.

The commissioners are to grant licences to horse dealers for not exceeding one year; and every licence shall cease on Sept. 29 in the year for which the same shall be issued, and commence from the date; and every licence taken out for any year subsequent to the year in which the same shall be issued, shall commence from Sept. 29 then next ensuing, and

continue till Sept. 29 following; and a fresh licence is to be taken out ten days at least before the expiration of the year.

One licence is sufficient for partners, and the licence is confined to the place mentioned therein.

But no licences to be granted to horse dealers unless they declare they seek their living by buying and selling horses, and add the name of the place where the said business is carried on. 29 Geo. III. c. 49.

Horse dealers, so licensed, shall cause the words *Licensed to deal in Horses*, to be painted or written in large and legible characters, either on a sign hung out, or on some visible place in the front of their house, gateway, or stables; and if he shall sell any horse, without fixing such token, he shall forfeit 10l. to be recovered by action, half to the king and half to the informer. 36 Geo. III. c. 17.

Horse dealers (not having a licence under the old act of 24 Geo. III. c. 31.) who shall after Jan. 1, 1796, carry on the said business without having obtained a licence under this act, shall be liable to be assessed to the duties on Riding Horses, and shall deliver lists thereof as other persons.

HORSE-HELPER, ALEXIPPOS, or portable SLIDING-LEVER, a curious invention, for which the thanks of the Society for the encouragement of Arts, &c. were voted to Mr. John Smart, optician, of Tooley-street, London. It is designed to be fixed to the under side of a cart, for the relief of the horse when thrown down and entangled in the thills. We earnestly wish, for the sake of humanity, to alleviate the cruelties to which horses are subjected, and hope the plan here given will at least afford a useful hint for further improvements in this line. This machinery will also afford some advantages in loading carts, where the common length of the cart is too short for the articles intended to be carried.

Views of this invention are given in Plate 34.

Fig. 1. A A A, plan of a common town cart inverted. B B, sliding bars or levers, i. e. the Horse-helper. C, cross-bar, or handle of the Horse-helper. D D, spring swivels or hooks to receive the ends of the ropes F F. E E, stops, to prevent overwinding the ropes. F F, H, ropes and hand-rings to project them. G, a prop, to prevent hanging the horse. H H, the bearing plates of the horse-helper, with pulleys or shivers attached thereto. I I, transverse cavities under the axletree to admit the passage of B B. K, the extra bar for country carts. L L, the handspikes for ditto. M M, the axletree or fulcrum. N N, n, the hind and fore ear breadths. O O, the extremities of the shafts. P, the back chain. Q, the prop.

Fig. 2. A profile view of the improved cart with the horse-helper upon a proper angle to clear the packing hooks, &c.

Fig. 3. A scale of feet and $\frac{1}{4}$ parts of a foot.

Mr. Smart's account of his invention is the following: "As all librating bodies," says he, "act in an exact and direct ratio to their elongations from the fulcrum, considered in connection with their proportion of weight, and *vice versa* (the first resistance by the inequality of their matter being excepted), it appears, that as is the solidity of the part of the lever resting on the fulcrum, to the solidity of its extremities, so is its resistance to be acted upon by a weight which is less than its disproportion; which inequality of power is to the weight added in an inverse ratio, but directly as the diminution."

It is evident that the construction of carts at present is very unfavourable to the relief of the fallen horse, who is intentionally placed at the longest arm of the lever (for the shafts act as a lever by supposing the axletree to be the quiescent fulcrum), that he may the better resist the weight of the load, should the equilibrium be by any means destroyed;

for any given weight upon the hind part of the cart has less than half the power of resistance of the horse; so that, if such horse falls, this advantage is prejudicial to his being raised. The inventor, therefore, of the horse-helper, presumes that a plan, the object of which is humanity, will sufficiently apologize for his offering to the public an invention which so obviously more than counteracts the before-mentioned disadvantages, as may be seen by inspecting the plan in connection with its scale.

"Let A A A (fig. 1.) be a plan of a common town cart inverted, whose hind ear-bred, or ear-breadth, N N, projects from its fulcrum, or axletree, M M, 4 feet 7 inches, while the back chain P is 7 feet 6 inches; and the extremities of the shafts, O O, which press upon the tugs in the horse's collar, are 9 feet 6 inches. Now, admitting that the horse who falls weighs 15 cwt. and that his bearing is 1 cwt. which is 16 cwt. it is very evident that it will require 3316lb. weight gross at the ear-breadth N N (which is but 4 feet 7 inches from the fulcrum M M) to counteract such a weight; even admitting that the load had not slipped forward at all by the sudden concussion and depression of the fore parts of the cart. The estimate, therefore, now will be nearly as follows: 4 feet 7 inches, or 55 inches, to 9 feet 6 inches, or 114 inches, will give for the weight 3316lb. which is more than that of twenty-two men, at 150lb. weight each, before a disabled horse can be raised from the ground: but we know that six men cannot bear their weight with advantage on one of our present-made carts, without endangering their persons or clothes; or both; so that the horse is left to struggle with three-fourths of the weight himself, and this in a very bad posture, as he is embarrassed by the shafts, &c. Hence many horses, if not immediately killed, are at least ruined for ever."

"The advantage of the sliding-lever is in the proportion of 126 inches, the length of the levers at C, to 114 inches, the length of the shaft, viz. O O; and this without the addition of the handspike L L, which gives a further advantage of one-fourth. Again, if 55 inches, the length of the lever, at N N, require 3316lb. weight, what will 126 inches require? Answer, 1447 $\frac{1}{2}$ lb. which is less than the weight of ten men, at 150lb. weight each. This, however, is not half the advantage of the lever, as it affords convenient accommodation for more than twenty men, without hazard to clothes or persons. And, if we suppose a sliding bar at K, one man (if men are scarce, as in the country), by applying the two handspikes L L, may gain power sufficient to raise his horse himself, especially as it fortunately happens that country luggage very frequently consists of such articles as might be removed from the front of the cart, and placed on the bars C and K; such, for instance, as sacks of corn, feed, potatoes, bran, flour, peas, beans, &c. &c. which, by being taken from the front, and placed behind, would have more than double the advantage of its real weight; and, in town, where the luggage is different, assistance is always to be obtained from bystanders.

"Notwithstanding the statement of powers for relief which I have here given," says Mr. Smart, "it is plain, from daily observation, that less than half the power here stated is only used in general, as eight or nine men can often (though with much danger and trouble) raise the fallen horse. Hence, by using the sliding lever three or four men, without danger, delay, or trouble, will be sufficient. As immediately the horse falls the driver has only to go behind the cart, lay hold of the hand rings F F, and at one pull the whole apparatus is projected; then lay hold of C, or B B, according as the case requires, and the horse will be instantly relieved."

Mr. Smart adds, that this apparatus is quite portable,

cofts but little, and adds not more than $\frac{1}{30}$ to the weight of the cart.

HORSENS, a sea-port of Denmark, in Jutland, seated on the bottom of a bay, which opens into the Categate near the island of Hiarnoe, 125 miles W. by N. of Copenhagen. Long. 9. 40. E. Lat. 55. 57. N.

HORSES. The following is the duty imposed on horses kept 38 Geo. III. c. 41. f. 2. There shall be paid for all horses kept for riding, or drawing any carriage chargeable with duty :

	£.	s.	d.
For one such horse, mare, or gelding, and no more	1	4	0
Two	1	16	0
Three	2	2	0
Four	2	5	0
Five	2	6	0
Six	2	10	0
Seven, and not more than eight	2	11	0
Nine	2	11	6
Ten, and not more than twelve	2	12	0
Thirteen, and not more than sixteen	2	12	6
Seventeen	2	13	0
Eighteen	2	13	6
Nineteen	2	14	0
Twenty or upwards	2	15	0

And by 41 Geo. III. c. 9. there shall be charged, from and after April 5, 1801, upon every person keeping one horse and no more, for which the duty of 1l. 4s. is now chargeable, an additional duty of 10s.

And upon every person keeping or using two or more horses, upon which a progressive duty is now chargeable, an additional duty of 20s. for each horse.

But the additional duties imposed by 41 Geo. III. c. 9. are not to extend to horses used solely in stages or carriages for conveying passengers for hire, nor to hackney coaches.

The said rates and duties to be paid by the person keeping and using the said horses, mares, or geldings, and to be subject to all the exemptions contained in any act in force. 38 Geo. III. c. 41. and 41 Geo. III. c. 9.

The act allows the following exemptions. By 24 Geo. III. c. 31., 29 Geo. III. c. 49., and 36 Geo. III. c. 16., it is provided that nothing therein shall charge any horse belonging to any non-commissioned officer, or private soldier, of any regiment of cavalry in the King's service; or any regiment of yeomanry cavalry; nor any horse belonging to, and kept for sale and not for hire, in the stable of a licensed dealer, nor let to hire for travelling post by the mile, or from stage to stage, or let to hire for a day or less period of time, by any post-master, inn-keeper, or person licensed by the commissions of the stamp duties.

Also no person who shall serve in any volunteer corps, and shall provide a horse, or who shall furnish a horse for any person serving in such corps, shall be charged for such horse, with any of the duties imposed by 38 Geo. III. c.

Also every rector, vicar, or curate, doing duty in his church or chapel, who shall not be assailed to any duties on income, granted by any act relative to the duties on income, and who shall not keep more than one horse for the purpose of riding, is exempted from the duty by 41 Geo. III. c. 40.

But not to extend to persons occasionally performing the duty of rector, &c. unless regular officiating ministers of the place.

The duties are to be paid by all persons using or hiring horses or carriages by the year, month, or any other period, not the person who lets them out; 29 Geo. III. c. 49.

Horse dealers are to give in a list of such as they keep for riding or drawing, and pay the duty; 29 Geo. III. c. 49.

No person keeping a horse, &c. used really for husbandry,

or drawing any carriage (except such as was heretofore liable to an excise duty), or carrying burthens in the course of the trade of the person to whom such horse, &c. shall belong, shall be chargeable with these duties, in case such horse, &c. shall not be used for any other purpose of riding, except when returning from any place to which any load or burthen shall by such horse, &c. have been carried, or going to any place from whence a burthen is to be carried, or being rid to procure medical assistance, or to or from market, or place of public worship, or election of members to serve in parliament, or to or from any court of justice, or to or from any meeting of commissioners of taxes. 26 Geo. III. c. 79.

Persons excused from church and poor, are also exempted for one horse.

Also no person occupying a farm of less than 70l. a-year, and making a livelihood solely thereby, shall be chargeable with the duty for any horse occasionally used in riding, if such horse be *bona fide* kept for the purposes of husbandry. 24 Geo. III. c. 31., 36 Geo. III. c. 16.

Likewise no person occupying his own estate solely, or his own estate together with a farm, the value of which in the whole shall be less than an equivalent to a farm of the rent of 70l. a-year (reckoning the value of the estate as equivalent to double the like amount of the rent of any rented farm) and making a livelihood solely by such estate, or by such estate and farm jointly, shall be chargeable for any horse occasionally used in riding, if it be *bona fide* kept and usually employed for the purposes of husbandry. 36 Geo. III. c. 16. f. 6.

Also stage-coach horses are exempted from the whole of the duties, by 37 Geo. III. c. 134. f. 8.

TABLE of the DUTIES on HORSES.

No. of Horses.	Duties for each.	Total Amount.
	£. s. d.	£. s. d.
1	1 14 0	1 14 0
2	2 16 0	5 12 0
3	3 2 0	9 6 0
4	3 5 0	13 0 0
5	3 6 0	16 10 0
6	3 10 0	21 0 0
7	3 11 0	24 17 0
8		28 8 0
9	3 11 6	32 3 6
10	3 12 0	36 0 0
11		39 12 0
12		43 4 0
13	3 12 6	47 2 6
14		50 15 0
15		54 7 6
16		58 0 0
17	3 13 0	62 1 0
18	3 13 6	66 3 0
19	3 14 0	70 6 0
20	3 15 0	75 0 0

And so on at the rate of 3l. 15s. for every horse exceeding the number of 20.

By 38 Geo. III. c. 41. f. 2. there shall be paid the following duties for horses, mares, and geldings, not charged with any other duty, and also on mules.

	£. s. d.
For each horse, mare, gelding, or mule, kept by any person, on which is now charged the duty of	0 6 0
By 41 Geo. III. c. 9, an additional duty of	0 4 0
The said rate or duty to be paid by the person keeping such horses, mares, geldings, or mules, and to be subject to all	

M. Snart's Horse-Helper or Sliding Lever for Relieving fallen Horses.

Profile View.

Longman's Patent Barrel-Organ.

Fig. 1.
Key Frame

the exemptions contained in any act in force, and not to be charged for any mule which shall not have been used. 38 Geo. III. c. 41., and 41 Geo. III. c. 9.

The exemptions are these: This tax does not extend to post horses, nor to any horse, mare, or gelding, under the height of thirteen hands, of four inches to each hand, nor to any horse, mare, or gelding, which shall not at any time preceding the assessment have been ridden, or used as a draught horse, or for the purpose of carrying any burthen, 36 Geo. III. c. 15.

But the horses for whom such exemption is claimed must be included in the list delivered to the assessors under the title of *Horses exempted from Duty*, and on demand must be produced for examination; and if not produced, or if found not to be exempted, the owner is to be surcharged double the duty.—*Ibid.*

Also, persons serving in any volunteer corps, or who shall furnish a horse for such service, shall not be chargeable with the duty. 37 Geo. III. c. 106., 38 Geo. III. c. 41.

Likewise by 41 Geo. III. c. 9. no person occupying a farm, the rack rent of which shall be less than 20l. a-year, and making a livelihood solely thereby, or occupying any other estate on any tenure otherwise than as tenant at rack rent, or such other estate together with a farm at rack rent, the value of which in the whole shall be less than equivalent to a farm at the rack rent of 20l. a-year, reckoning the value of every estate occupied by the owner thereof on any tenure, except at rack rent, as equivalent to double the like amount of any farm at rack rent, and making a livelihood solely by such occupation, and keeping not more than two horses or mules, shall be chargeable with any of the duties imposed either by the former or this act. So as the persons claiming such exemption return in their lists the number of horses kept, and the value of their farms.

HORTSMAR, a town of Westphalia, in the bishopric of Munster, 15 miles N.W. of Munster. Long. 7. 2 E. Lat. 52. 9. N.

HOT-BEDS (*Encycl.*). These are of such general use in the modern art of gardening, that any method of improving them deserves the notice of every gardener.

Mr. Richard Weston, of Leicester, has described a *water-flue* in the thirteenth volume of the Repertory of Arts, &c. p. 238, which is capable of being employed in a double manner; that is, it may convey heat into a hot-bed, either by the steam of water, or of dung. In places where hot water cannot so conveniently be procured, and where there is plenty of dung, this will be found very useful.

Those persons who already have a water-flue, may alter it for the expense of two or three shillings, to answer both purposes.

The alteration necessary consists in changing the pipe of one inch diameter (which is to draw off the water when cold), into a larger one of three inches, and to have the head of a watering-pot of six inches diameter made of tin, with a pipe of one foot long to put on it, with holes of a quarter of an inch wide to admit the steam, both in the pipe and rose.

When you choose to heat a hot-bed with steam, the bed must be made in the usual manner, except that in the front, or at one end, with oblong pipes, the dung should be laid about a yard square, to form a strong body of steam, to pass into the flues, and convey the heat to the earth, and the roots of the plants; but three good corks must be first put into the two upright steam-pipes within the bed *c c*, and the one on the outside *c*, by which the flue is filled with water to prevent the steam from passing off through them.

To examine the heat of the bed at any time, draw out the cork, and the heat of the steam will inform you of the condition of the bed. If declining too much, the dung must be stirred up, and fresh added.

If at any time dung cannot be readily procured, it may instantly be converted into a water-flue.

On applying to a plumber, who had made several, it seems that instead of their being made oval, if two pipes of eleven feet long each (for a nine-feet frame), turned up a foot at one end, to fill them with water, and one or more upright pipes to each in the middle, to convey the steam of the hot water into the bed, be laid lengthways in the bed, about three feet asunder, there will be a saving of six or seven shillings on account of less solder, and trouble in making, and will be found rather more convenient, as appeared from one made which is at work.

The use of steam from hot water was also proved by a gentleman, who observed his cucumber-plants declining in vigour, and not having a water-flue, placed four jugs in the bed, and filled them with hot water for three nights, till the fresh lining took effect, which instantly recovered his plants, and he afterwards had a flue.

Indeed, the introduction of steam from hot water, in increasing the growth of cucumbers is very strongly proved from the experiments of Mr. Wakefield, published in the same work.

"In a frame consisting of three lights," says Mr. Weston, "I would propose four, or even six steam-pipes, and if the top of each be enlarged to four inches in diameter, in the shape of the bottom of a trumpet, it will convey more steam into the bed. In pl. 33. this is represented. *a*, shews the pipes to fill them. *b*, steam-pipes. *c*, to draw off the water, or put on the rose when converted into dung steam-pipes.

"From the proofs also of steam being so advantageous to cucumbers, I would recommend a pan, made of copper, brass, or lead (six inches wide and three deep, with a pipe, one foot long, to come through the end of the frame, to draw off the water when cold), to be placed at the back of the hot-bed frame, to be filled with hot water at night, and if necessary again in the morning.

"If a hole be bored assant through the back of the hot-bed-frame, the pan may be filled with hot water, without the glass being taken off; and I would rather recommend the flues to be four inches diameter within, than three, because of containing more water or steam."

HOT-HOUSE, a building calculated to produce fruit or flowers from plants before the arrival of the natural season; or else to preserve alive such as are natives of warmer climates.

The following is the specification of a patent granted to Dr. Anderdon, of Aberdeen, for a method of economising fuel in the heating of houses, and for improving the construction of hot-houses by a new application of known principles. It is dated Feb. 10, 1807.

"Let the heated smoke, as it issues from the fire, be conducted into a chamber that will be most commodiously situated beneath the floor of the house or apartment intended to be heated; extending the whole of its length and width, if it can conveniently be done, leaving only a vacancy between the inner side of the wall of the house and the wall of the smoke-chamber, all round, of two feet or thereabouts; no precise nicety as to its dimensions being requisite; the chamber for the smoke may be of any form or dimensions so as to suit the situation, and from two to six feet or more in depth, as circumstances will admit (the deeper always the better); and the roof of it ought to be below the level of the floor of the house or apartment intended to be heated, so as to leave a vacancy there of one foot, at least, in depth, and if two feet or more, so much the better. The roof and sides of this smoke-chamber should be made air-tight, and may be constructed of plates of metal, or any other matter that is capable of bearing heat, and of easily transmitting it, and of being made air-tight. The grate where the fuel is to be consumed ought to be placed lower than the floor of this chamber, if it can conveniently be done, (but this is not indispensably necessary), and the chimney leading from the fire ought to rise upwards within the smoke-chamber till it reach within about one foot of its roof, where it should be discontinued and left open, having a spark-flare or cover laid over it to spread the heat. The chimney for carrying the smoke from this chamber, and for making the fire burn, should communicate with the chamber near the floor or bottom of that chamber, and in no other place, unless occasionally for particular purposes, by an opening formed into it immediately below the roof of the smoke-chamber, which is shut, in general, by means of a valve that can be opened at pleasure. This chimney may either rise directly to the height of the building, without interruption, or it may be made to open into a succession of chambers of a similar construction to the smoke-chamber just described, as far as respects the transmission of the smoke, though they may be varied in all other respects to suit the circumstances of the case *ad infinitum*: that is to say; these chambers may vary in size, shape, and proportions; in position, being either above or below, or upon the same level with the original chamber, and so on. But although the best position for the smoke-chamber be directly beneath the building to be heated, yet, should obstructions prevent this, it may be placed without it, or under some other building, as near the building that is to be heated as may be.

"Connected with the original smoke-chamber, there may be formed another of an auxiliary sort, which should also be air-tight in the roof and sides. This auxiliary smoke-chamber should communicate with the first by means of two pipes, that can be closed or opened at pleasure; one placed immediately above the floor, and the other next the roof of the principal smoke-chamber; and it should also communicate with the open air by another opening or pipe issuing from the bottom of that auxiliary chamber. This last pipe ought to have a valve to stop or open at pleasure, and should always be closed when the fire is burning, and opened whenever it is extinguished, the lower opening into the principal smoke-chamber being closed at the same instant that the other is opened; and if there be no auxiliary smoke-chamber, an opening of this sort must be made into the principal smoke-chamber. Either at the top, or in any other convenient

part of the chimney, should be fitted a valve or stopper, which admits of being opened, or perfectly closed, at pleasure. When closed, it will stop circulation, and soon extinguish the fire. Whenever it is closed, the air-hole of the furnace (if the heat be not required for another chamber) ought also to be closed, and the fire will then be instantly extinguished; and the chamber being full of heated smoke will gradually transmit that heat through its cover and sides to the air-chamber which surrounds it: the hottest part of the air thus heated will rise to the top. As the heat in the smoke-chamber gradually abates, it will, of course, contract in bulk; and, by thus forming a kind of vacuum, must then draw in a supply of air from the auxiliary smoke-chamber to supply that want. As the higher opening into that chamber alone is now open, it must draw in now only the hottest part of the air, while the air from without is drawn into the bottom part of the auxiliary chamber; and as it will continue to occupy the lowest place, no cool air can be drawn in, until the whole of the heated air shall be exhausted.

"The vacancy immediately above and around the principal smoke-chamber is intended for an air-chamber: the floor above which, and its sides all over, must be impervious to air or water, and may be formed of flooring tiles or stone, or any other material proper for such cases that can be got cheapest at the place. From this air-chamber let a pipe or pipes pass into the apartment intended to be heated, that can be opened or closed at pleasure, and that can admit at pleasure also of being opened either immediately below the floor, or at any greater depth, so as to allow air, more or less heated, as shall best suit the purpose, to pass into the apartment intended to be heated. This heated air may (when thus admitted) be either allowed to spread in the apartment immediately above the floor, so as to heat the whole of the apartment; or it may be conveyed nearly to the roof before it is let loose, so that the upper part of the apartment may be heated to a great degree without affecting the lower part of it, if it should be so required.

"Connected with the air-chamber may also be an auxiliary air-chamber, capable of retaining the heated air; between which two chambers, there should likewise be a communication by means of a pipe; and this auxiliary air-chamber should also communicate with the common air by an opening just above the floor of it in the lowest place, and no-where else. The pipe that communicates between the air-chamber and its auxiliary, should be so made as that the end of it which enters into the principal chamber, should be placed just above the floor, and the other end of it should open into the auxiliary chamber high up, very near the upper part of it, and should never be closed. In consequence of this arrangement, when the air in the principal chamber, or heated air, comes to be heated, if the pipe communicating with the apartment above be kept shut, then as the air expands in consequence of the heat acting on it from the smoke-chamber below, the coldest part of the air in that chamber will be forced to pass into the auxiliary air-chamber, which, in its turn, will force some from thence into the open air. In this way, after the cold air is all discharged from the principal air-chamber, some part of the heated air will be driven into the auxiliary air-chamber, in which, assuming the highest place, it will there be retained, forcing the colder air below to pass out into the atmosphere. The process must be continued as long as the air in the internal air-chamber continues to augment in heat, but when a portion of that heated air is let off into the apartment above, or when the fire is slackened so as to communicate no more heat to it, then in that case a suction will be made from the inner chamber so as to draw in air from the auxiliary air-chamber; but as the pipe opens into

the higher part of the chamber, it will draw back only the hottest part of the air in it, and so on it will continue to draw back the superfluous air so as to derive the whole benefit of it without any waste whatever. But although this auxiliary air-chamber will be of great utility, it may, nevertheless, be dispensed with if the owner so chooses: but the opening into the air-chamber below is indispensable.

"If the apartment placed above, and communicating with the principal chamber of heated air, be intended to be employed as a hot-house, its walls ought to be made of glass all round, if circumstances will admit of it, on the north as well as towards all other points of the compass; thus to obtain not only the benefit of the sun's heat to the fullest extent, but also to obtain as much light as possible, which is of the utmost utility to plants of all kinds, as, without it, they cannot be preserved in good health. The whole should be made air-tight. The under part of each of the front glasses should be so formed as to admit of being opened, or to shut quite close at pleasure.

"A row of windows, or air-holes, that admit of being opened at pleasure, should be placed along the north, or other sides, towards the top, with this single variation, that they should be made to open alternately from below; rising upwards, or from above falling downward, but so as always to admit of being shut so close as to be air-tight. These openings are to serve the purpose of emitting the air at pleasure, and assisting in ventilating the house. The edges of the door should be also so made as to shut quite close.

"For the purpose of a *pinery*, or *vinery*, or peach-house, and most other uses to which a hot-house is usually applied, the roof of the apartment (in other words the hot-house) should be placed in a horizontal position, or nearly so, something like the ceiling of an ordinary apartment, only that that ceiling should be made of glass instead of plaster, and should be fixed to the joists above, and made altogether air-tight. The vines or other fruits intended to be forced may be extended close under the glass. The bed in the stove should be raised so high as to be as near the roof-glasses as the leaves of the plants in it will permit. Pipes of different lengths, which may be opened or shut at pleasure, ought to be passed through the upper-part of the hot-house for the purpose of letting off the heated air to that degree which shall be deemed eligible at the time, and should reach to that depth in the house that shall be thought proper, for the purpose of regulating the heat of the stove, and keeping up an equality of temperature at all times without any attendance from the gardener. The stove being first made air-tight everywhere, let a pipe be placed in the floor, communicating directly with the chamber of heated air below; and let the top of that pipe be closed by means of a light valve that opens upwards. Let another pipe be placed above, that may communicate with the open air, if judged proper, having a light valve upon its upper end opening upwards also. Let an opening be then made into the stove near the floor, so as to admit a free communication by that means with the open air; lift up then the valve of the bottom pipe, the heated air will rise upwards through it into the stove, gradually filling it; while the cool air that was in the chamber is imperceptibly driven off through the opening below into the atmosphere.

"When the stove has gradually acquired the degree of heat required (say ninety degrees of Fahrenheit's thermometer), shut the opening below, and all others, quite close. The hot-house being now air-tight, it must follow, that if more heated air arises from below, it will tend to expand the air already in the hot-house; in other words, to raise the temperature above ninety degrees. But in consequence of that

expansive effort from within, an effort will be felt to close the lower valve (as is felt in a bellows when the two handles are pressed together), so that no more heated air can find access by that means. The same expansive effort will have a necessary tendency to open the upper valve, and thus heated air will be allowed to escape until the air in the chamber has come into an equilibrium with that of the atmosphere; or, in other words, till it be at ninety degrees, at which temperature alone it ever can, as thus regulated, attain that equilibrium.

"If, however, from the coldness of the night air, or from any other cause, the heat of the stove should be diminished, so as to fall below ninety degrees, the bulk of the air in it will be at the same time contracted, and a kind of vacuum be experienced. In that case, in consequence of the suction inwards, the upper valve would be firmly closed, so that no cold air can be there admitted; and, from the same cause, the lower valve will be opened so as to admit heated air again from below. In this way, as soon as the temperature shall attain the ninetieth degree, or such other regulated degree of heat as shall have been fixed upon, the lower valve would be closed, and thus an equal temperature would be kept up within the house at all times, whatever variations might take place in the atmosphere, without the attendance of any person whatever. If care be taken to keep up the heat in the air-chamber above ninety, or the regulated degrees, and provided the apartment above it (the stove) be perfectly air-tight, the variation of heat that could prove hurtful to the tenderest plant could never be experienced.

"In the *vinery*, peach-house, and others that require nearly a similar temperature, where the sun becomes the principal, if not the sole, source of heat, an auxiliary chamber ought also to be provided for receiving the heated air when there is an excess of it, and restoring it back again during the night-time, when the cold or other circumstances render the contraction within sensible. This auxiliary chamber should be constructed exactly in the same manner with those already described. In this case also, as in the former, though the pipe of communication opens also into the auxiliary chamber near its roof, it ought to be made to issue from the hot-house itself, either higher or lower at pleasure, which may be effected by fitting upon its orifice pipes of different lengths. As it may be convenient to rear vines entirely on the outside of the house, proper openings ought to be provided for introducing the vines from without, and for withdrawing them at pleasure. These openings may be made either immediately under the roof of glass, or occasionally just above the floor of the hot-house, as shall suit the inclination of the owner. They should consist of horizontal slits of a length and depth sufficient to admit of the shoots being passed through them with ease, and admit of being closed either with a case with glass in it, or a wooden frame, the openings between the shoots being closed up with soft moss, close rammed, so as to be air-tight, or with a plaster of grafting loam, or any other soft material that is fit to prevent the passage of the air without too much cramping the shoot.

"Peaches and cherries, which require the influence of the open air in the winter, may be raised in large tubs or boxes that admit of being removed; and if the stems be trained perpendicularly, nearly as high as the horizontal roof glass, and then bended over and trained horizontally, they may be admitted into the house, or withdrawn from it through horizontal slits, similar to those above described, which admit of being closed in the same manner.

"For the purpose of forwarding lettuce, or other low-growing plants in winter, or strawberries early in the spring, let a set of frames be provided, consisting of open spars strong enough to support the weight that is to be put upon

them; each of these frames should be of such dimensions as to hold three rows of pots of the usual size for that purpose, and of a length the whole width of the house, wanting two feet or thereabouts. A set of pans or boxes, made of any light material that can hold water, and having edges turned up one inch, should be provided to be laid on these frames, and into these pans or boxes the pots should be placed. These frames may be suspended from the ceiling or roof of the chamber by means of cords passed over pulleys, so as to admit of being raised or lowered into a warmer or cooler region of the chamber at pleasure. The plants may be supplied with moisture by pouring water into the pans without lowering them, and the fruit may be seen, without moving them, through the glass above.

"Hitherto it has been the practice to have no hot-houses of more than one stage or story in height, but upon the present plan, in situations where they can be secured from effects of wind, nothing is to prevent them from being of two or more stages or stories; and where this can be safely done, it will prove a considerable saving on account of the roof. In that case, all the difference that will occur between the first and higher stages is, that the floor of these last, as well as the roof, will be of glass. A foot-path of wood or grating for the gardener should be always, in that case, formed along the inside of the north wall, having a slight rail on the inside, of about three feet high, like the rough tree of a ship; or otherwise, to guard against accidents; and a loose deal ought also to be provided to be shoved along to the top of the joists, when wanted, as a platform for the necessary purposes. Over the highest stage or story must be thrown a roof, the south side of which, and the east and west ends, may be made of glass, and the north side either of glass or proper opaque materials. This may be so constructed as to be employed for the purpose of a vinery, and at the same time of a reservoir-chamber for heated air, which may be freed from its superfluous heat, when that becomes too great, by means of a tube from the top, which admits of being opened or closed at pleasure.

"With a view to obviate the bad effects that might occasionally result from too great a degree of heat in the higher regions of the hot-house, continued too long through accidental inadvertence in the gardener, the following apparatus may be used. Take a bladder, or other flexible bag, that is impervious to air, turn the mouth of it, while it is open, upwards, and heat it then to a considerable degree before a fire, or otherwise; when it has been made to attain a degree of heat higher than that of the hot-house, tie the neck close while it is not yet fully distended, though nearly so, taking care previously to fix a string to the bottom of it, by tying in a part of it, or otherwise. Then attach it to some fixed object; afterwards turn the house to a proper degree of temperature, and while it is in that state fasten the string that proceeds from the bag tight to some other object, the consequence must be, that when the heat augments the bag will become more distended, and, consequently, will augment in diameter, and contract in length, so as to tighten the cords, and when the heat abates it will become more flaccid, and of course slacken the cords, so that this may be employed as a moving power to open or close a valve as it contracts or dilates; and it will necessarily regulate the heat of the house by its spontaneous movements, without requiring attention from any one.

"For the purpose of agitating the air in the house at pleasure, without the necessity of introducing air from without, and for many other indispensable purposes, the following apparatus has been contrived:—Make a cylindrical box of

a construction similar to that of a drum; pass through it length-wise an axle, carrying arms of thin wood, or other light and firm material, to act, when put in motion, as a fan. This axle is to be properly supported at each end, and in such manner as to leave an opening at one or both of the ends for the purpose of admitting air to the fan. The fan may be moved by means of a simple handle, or, if greater velocity is wished, by a large wheel at one end, acting upon a pinion upon the end of the axle, or by a large screw acting upon a small one, connected together by a band, belt, or chain. On one side of the cylindrical part of the drum leave an opening for the passage of the air when the fan is in motion, to which can be fitted at pleasure a pipe that admits of movements, and of being occasionally lengthened or shortened; it may be flexible or otherwise, as shall suit the circumstances of the case, terminating in a small nozzle to admit of its being directed to any point where it may be wanted. Let the mouth of another pipe, similar to the above, be so formed as to cover the end, opening, or openings of the drum, for the supply of air, so that all the air that can pass into the drum must first pass through this pipe: by means of this apparatus, the air can be sucked up by the machine from any part, either within or without the house, and spouted out into any other part of it, with a greater or less degree of violence, as circumstances shall render eligible. The machine itself may be driven either by the hand, like a common winnowing machine, or it may be driven by means of a vane, moveable by the wind, placed on some convenient part of the building: or by water, or steam, or horses, or any other moving power, which circumstances may render eligible. Or this kind of ventilator may be produced by means of a bellows, having pipes of the sort above described, adapted to the nozzle and the under valve of the bellows.

"With a view further to economize fuel when that becomes necessary for the production of heat, care should be taken to have the whole of the smoke that arises from the burning fuel consumed. To effect this, let a fire-place be constructed in the following manner:—Let this fire-place have two grates, so connected as to admit of communicating alternately with each other: each grate should have two air-holes opening into the cavity below the grate, being close every-where else: one of these air-holes should communicate with the atmosphere directly in front of the grate, and the other with a passage below, that goes directly from the one grate to the other. These two air-holes should admit of being opened or closed at pleasure, but so as they can never be both open at the same time unto the same grate; this may be conveniently effected by a shifting door, or valve, which, when it closes the one hole, must necessarily open the other. For the sake of distinctness, let one of these grates be called No. 1, and the other No. 2. When the fire is to be lighted, let the air-hole in front of the grate No. 1 be opened, and the other air-hole to that grate will of course be closed. The coals in No. 1 being then kindled, the smoke, as it issues from the fire, should be conducted at first right upwards for a small distance, and it should then bend in the same plane with the wall, so as to assume a horizontal position, and in a direction pointing towards the other grate No. 2. It should then bend downward, still in the same plane, and proceed in that direction until it comes into the passage that leads from the one grate to the other beneath the level of the grates respectively. As the opening from this passage into the grate No. 1 is at this time closed, the air-hole in front being open, the smoke must pass on towards the other grate, No. 2, whose air-hole in front being now closed, it can receive no air to keep alive the burning fuel but that which comes through that passage;

and as this air conveys along with it the whole of the smoke that came from the burning fuel in the grate No. 1, that smoke, in passing through the fire No. 2, will be inflamed and entirely consumed, thus tending greatly to augment the heat. It being always understood that the fuel in the grate No. 2, is at this time in the state of charred coal, having been kindled previously to that in No. 1. After passing through the grate No. 2, the heated air rises at first through the chimney of No. 2, in a perpendicular direction, to the same height as that of No. 1. It then bends in a horizontal direction towards No. 1, in the same plane with the wall; from thence it bends backwards in a horizontal direction for a small space, and may be then carried off through a chimney in any other direction that convenience can suggest. But when the fuel, that had been put upon the grate No. 1, shall be so far consumed as to emit little smoke, let the front air-hole of No. 2 be opened, and fresh fuel be put upon it, the other air-hole of that grate being necessarily closed when the front air-hole is opened. The smoke arising from thence, will now pass upwards as before, but, instead of going back into the chimney as before, a moveable door or valve there being shifted, that opening is then closed, and another opening made into the same chimney to receive the vapour arising from the fire No. 1. The smoke will then be obliged to pass downwards, and should be conducted in the same manner as that before described of No. 1, into the passage that communicates between the two grates, and thus be forced to go under the grate No. 1 (the air-hole leading from that passage to No. 1, having been previously opened by shutting the air-hole in front), where it must pass through the fire and be inflamed, from whence it rises up, and passes off through the chimney, as that from No. 2 did before.

“Observe that at the place where the smoke enters from above into the passage that leads between the two grates, there is a moveable valve, which is opened at the same time that the said air-hole into the chimney on that side is shut; the said valve, when it opens, thus closing the similar opening belonging to the other grate. Thus may the two fires have fresh fuel put upon them alternately, and be interchangeably shifted as often as can be wanted so as always to consume the whole of the smoke. The form and situation of these chimneys, grates, and valves, may be varied at pleasure, preserving the principle of causing the unconsumed smoke to pass through the fire that has ceased to smoke.

“For the purpose of obtaining steam when wanted, let the upper part of the chimney above described, where it runs in a horizontal position between the two grates, be made of such a width as shall be deemed convenient, and that upper surface should consist of the flat bottom of a pan; or a flat pan may be placed above any kind of grate. Let a chamber be made above that, whose tops and sides are formed by a vessel containing water flat above, but projecting downward all round to the depth of several feet, so that water shall surround the chamber on all sides, except at the bottom part, which is the pan. The edges of the water-chamber should go an inch or two lower than the pan, being wider than it; and an opening should be left below the edges of the water chamber. Within this chamber, and immediately over the pan, let there be placed another vessel containing water. The pan is to be used for boiling and evaporating water. It is to be supplied with water from this inner vessel, in proportion as it is evaporated, by means of a ball cock or float, and that vessel, in its turn, is to be in like manner supplied with water, as it is drawn off from the outer vessel that surrounds the chamber; so that it will be always heated before it reaches the evaporating pan. The steam that is first raised, will fill

the chamber above described, where it will accumulate until that chamber be wholly filled, so as to make its escape below the bottom of the sides, from whence it may be conveyed, by a proper conduit, into a house, when it is there wanted. A pipe should also be taken through one of the sides, close below the upper part of what may be called the ceiling of the water-chamber, that admits of being opened at pleasure, by means of which the whole of the steam can be let off when it shall be judged proper. But as it may often happen that steam will be wanted only in moderate quantities, and at particular times, so as to render it unnecessary to continue the evaporation of water during the whole time that the fire burns; in that case, the following apparatus may be resorted to. By means of a bellows formed for that purpose, or a forcing pump, throw in a small shower of water from time to time, into the dry bottom of the pan, properly guarded by tiles laid above the bottom, so as to cover it when fully heated, which will be instantly converted into steam; and, after a short interval, another and another, until as much steam shall be generated as shall be wanted at that time, when the evaporation may be discontinued.

“For the purpose of obtaining a moderate degree of heat occasionally, without being under the necessity of lighting a fire in the house, the following apparatus may be adopted.—Make a hollow cylinder of metal, or other matter that is capable of retaining smoke and transmitting heat, open at bottom, but close at top. This cylinder ought to be of considerable proportional depth, and of a size proportioned to the use intended by it. The sides of this cylinder may do for some purposes if only single; but, in general, it ought to be double, leaving an opening between the two cylinders all round of about an inch or more in the clear. These two cylinders should be joined close together at the bottom, and the outer cylinder should rise somewhat higher than the part that closes the inner cylinder above; round the top of the outer cylinder should be formed a horizontal rim, of such a breadth as to admit of being depressed into a circular groove all around it, for the purpose of receiving a perpendicular rim running round the lower part of the cover, like that of the lid of a tea-pot. The cover itself may be made of such shape and dimensions as shall best suit the purposes intended at the time. Let the cylinder thus prepared, be heated to the degree wanted, by an Argand's lamp placed within it, which, instead of a glass tube to receive the flame, has one made of metal fitted to it, which is of such a length as to reach from the lower edges of the cylinder till within half an inch of the top of the inner cylinder; or it may be heated by suspending it over a good fire, upon a crow or otherwise, until it be sufficiently warmed, when it may be carried into the place where it is wanted, and there suffered to stand till it communicates heat to the surrounding bodies. If water be put into the upper cavity above the top of the inner cylinder, the cover being at the same time taken off, steam in small quantities may be raised in the house where a greater degree of heat is wanted; and, for long continuance, this apparatus may be made of very large dimensions, and of any form that may best suit, and fixed in its place. The sides may be made of bricks, or other solid substances, and a culinary fire adopted instead of the lamp, so that its power may be thus augmented to such a degree as to answer many important purposes.”

HOËAT, an island of France, between that of Belleisle and the Continent. It is 10 miles in circumference.

HOUDAIN, a town of France, in the department of the Straits of Calais, six miles S. of Bethune. Long. 2. 34. E. Lat. 50. 39. N.

HOUDAN, a town of France, in the department of Eure

and Loire. It has a manufacture of woollen stockings, and is seated on the Vegre, 32 miles S.W. of Paris. Long. 1. 41. E. Lat. 48. 47. N.

HOULSTON (Thomas), an eminent physician and active philanthropist, was born at Liverpool, on the 26th of November, 1746. After a good classical education, being designed for the medical profession, he made himself acquainted with pharmacy, and spent a considerable time in medical attendances in London, where his extraordinary diligence and eager-desire of information attracted the notice and partiality of Dr. George Fordyce, to whom he afterwards dedicated his Inaugural Thesis. To demonstrate the sufficiency of his acquirements, even before the usual course of study in that then most celebrated University, he took the degree of Doctor of Physic, at Leyden, where his abilities obtained him distinguished marks of approbation from the professors Albinus and Gaubius, &c. As he was yet only of the age of twenty-one, and his natural thirst after knowledge was by no means satisfied, he travelled through the Continent for further improvement, and visited most of the foreign universities. This tour, in which he was much distinguished and employed by English travellers of rank, occupied him upwards of seven years, his stay being considerably prolonged in those parts of the Continent where the salutary practice of inoculating for the small-pox had either not been introduced, or had declined under the prejudices of the people. In this pursuit he laboured with a degree of zeal and perseverance that obtained him great celebrity; and at Vienna, where he continued about two years, he most effectually established the practice, and was honoured by the late Emperor Joseph II. with a long conversation on that subject. But—"envy will merit, like its shade, pursue"—such distinguished patronage could not but subject the doctor to opposition even where before he had experienced support. The celebrated Van Swieten, sacrificing candour and the good of his fellow creatures to the artful insinuations of Brambillo, an Italian surgeon employed by the court, became the discourager of inoculation; and the latter, who necessarily took a part in the inoculation of the then King of Poland's nephew and niece, exulted in (if he did not infamously promote) the unfortunate event of the loss of an eye to the princefs. This, though a mere consequence of serofulous inflammation, and much more likely to have happened under the natural small-pox, checked the progress of inoculation among the higher ranks, and had, no doubt, a corresponding effect on the stronger prejudices of the multitude. This obstacle, however, produced only temporary effects; and Dr. Houlston had the satisfaction of witnessing the preservation of thousands by inoculation, before he returned to his native country, which he did in 1771 or 2, preferring his native place, where he might enjoy the society of his family for the rest of his life, to the more splendid prospects of medical practice in the metropolis.

In this more limited scene, where there existed fewer incitements to professional exertion, he nevertheless enjoyed an abundant share of celebrity; but here the predominant feature of the doctor's character, which was philanthropy, rather superseded the usual anxiety for medical pre-eminence. This propensity also acquired strength with the decline of his health,

a fixed distrust of life and its pursuits, and a growing confidence in the promises of Christianity, of which he was a firm believer. At this period, the shades which mark the human character, it is said, were not unobserved by the most partial of his friends; yet, his errors were of that venial sort which unfortunately disgust without injuring mankind. His continual charities to the poor must protect his memory from the insinuations of those who accuse him of an undignified partiality to the means of affording them; and the sum of his good deeds must be balanced against those failings, which too uniformly deteriorate the character of man.

He wrote, 1. Dissertation inauguralis de Inflammatione. 2. A Method of treating the Small-pox (a translation). 3. An Essay on Poisons, in which the means of counteracting those of the mineral class was first suggested; (see Poisons, Supp.) 4. A paper on the preservation of those who are in danger from having drank largely of spirituous liquors. Several other of his productions, particularly those calculated to extend the means of recovering drowned persons, are to be found in fugitive publications.

Doctor Houlston died in 1787, after labouring a long time under the effects of an incurable fistula. He was, from the first of his settling there, physician to the hospital at Liverpool; a member of some of the learned societies; and, what is not generally known, he was the great grandson, by the mother's side, of President Bradshaw.

HOUSE OF CORRECTION, a place where crimes are punished by confinement, discipline, and extraordinary labour; (see BRIDEWELL). The mode of remedying the defects and abuses existing in these establishments, will appear from the following account of the jail and house of correction at Dorchester, by William Morton Pitt, esq. M. P.

The building of the new jail, at Dorchester, and the reform in the management of the old one, began in 1790. The old house of correction at Sherborne was sold in 1794, and its prisoners were transferred to one of the wings of the new prison, which was then appointed the house of correction for the county. From that period, both establishments have been under the direction of the same keeper, and under the inspection of the same magistrates; and have had but one chaplain, surgeon, &c. The present prison, built on a plan approved by Mr. Howard, cost £. 16,179. 10s. 6d. and was first occupied in December, 1793. It contains eighty-eight sleeping cells, besides those for the condemned, the reception cells, and working cells, which are all *single*—the infirmaries, two large dormitories for male debtors, in addition to the cells in the debtors' wing, and two for female debtors and female fines, and also dark *single* cells for the refractory. Each dormitory contains four beds, but is capable of containing more in case of necessity.

In 1791, manufactures were introduced, for the employment of all such prisoners as either were compelled by law, or could be induced by encouragement, to work. Convicts, and all persons sentenced to imprisonment and hard labour (to whom the law has not already allotted any certain portion of their earnings), are allowed one-sixth part thereof, besides broth in addition to their bread; and, if they earn to the amount of five shillings per week, they are also allowed meat*.

* In many of our houses of correction, the prisoners, even to this day, are fed chiefly, and *without distinction*, on bread and water; a diet that has been found to have a tendency to dropical complaints; and that has as little good effect on the health of the culprit, as the indiscriminate system of treatment, devoid of inducement or encouragement, can produce on his morality and industry. The persons confined might be very comfortably fed, at the same expence as they now are on bread and water; especially if a difference was made in the diet of the industrious and well behaved, and of the idle and vicious, as has been done with great effect at Dorchester. That, and the securing to them a fixed and liberal interest in their labour, to be paid them on their discharge, would produce an immediate change in our prisons and houses of correction; and make them really the in-

Debtors, and persons committed for trial, not being compellable to work, enjoy the whole of their earnings, if they purchase their own raw materials and sell the produce on their own account; but, if they are supplied with the materials, and the county has the risk of the sale of the goods, they have then only the half of such earnings.

In all cases, except where debtors and others voluntarily working, provide themselves with materials, the jailer is allowed one-sixth of the earnings, as a gratuity for his extra trouble, and as an incitement to further exertions; and the remainder (after deducting the jailer's and prisoners' shares) is placed to the credit of the county. The full amount, however, of the shares of the earnings, except those of debtors, are not paid to the prisoners until their discharge, but are carried to their respective accounts; and two pence per week only is allowed them for the purpose of procuring for themselves any little indulgences, consistent with the police of the

prison; even the sums placed to their accounts being liable, in the whole or in part, to forfeiture, in case of misbehaviour. There are instances of men who have received eight or ten pounds, or more, on quitting the prison; and the money has for the most part been laid out by them in clothes, tools, furniture, a flock of bacon, or other provisions, &c. for their future comfort and advantage*.

The produce of the work, the expence of maintenance, &c. are stated in the table, No. I. In No. II. is added an account of the manner in which the donations left the prison, and other charitable contributions, have been applied, in liberating and assisting debtors, in aid and relief to other prisoners discharged at the assizes or sessions, and in rewards to persons who have heretofore been in confinement, and who have obtained certificates, properly authenticated, of their industry, honesty, and good behaviour, in the services in which they have been since they have left the jail.

TABLE. No. I.

Number of prisoners, account of earnings and salaries.

	1791.	1792.	1793.	1794.	1795.	1796.
Average number of prisoners in the several years - - -	40	47	50	50	51	49

instruments of correcting, instead of their being as at present the means of increasing habits of vice, dependancy, and idleness. The wild beast may be starved into submission, or compelled to subjection; but beings endowed with reason, and destined by their Creator for social intercourse, are not to be reformed merely by solitary confinement, by depression of condition, or privation of food: there must be added—encouragement to those who do well—distinction between them and the ill-behaved; the objects of labour must be made easily attainable, and its consequences and advantages desirable.

* It were much to be wished that the example of the reform of Dorchester jail and house of correction were followed in every prison and house of correction in the kingdom. The reader will perceive that it has been produced, by securing to the prisoner, not only a preference in diet and accommodation, but a *certain and liberal share* of the earnings of his industry, and by husbanding that produce for him against the time of his quitting the house; so that he may go out, not only with habits of application and with character, but with the means of subsistence, and of carrying his industry to the most advantageous market. To expect, from the general mass of mankind, a *willing continuance in labour from day to day*, without the spur of interest, without an object of expectation, and without the engagement of the inclination by a share, at least, of the profits,—or to hope for success in the attempts daily made, in our houses of correction, to *compel* prisoners to work, not as the means of increased comfort and advantage to them, but as a *punishment* of their offences, is absurd and ridiculous.—Compare the difference between that which persons may be *induced*, and what they may be *compelled* to do.—In the spinning-school at Epping, a little child, of 9 years old, will, with cheerfulness and pleasure, and without abridging its hours of play and recreation, earn four pence a-day; and will dine plentifully and comfortably, for a penny; while a stout active man, in the prime of life, in one of our houses of correction, with an allowance of *nine pence* a-day for his food, is (in a state of mortification and suffering) earning one penny a day in picking oakum.

† N. B. The working system did not commence till late in the year 1791.

TABLE. No. II.

Application of donations and charitable contributions.

	1792.	1793.	1794.	1795.	1796.
	£. s. d.	£. s. d.	£. s. d.	£. s. d.	£. s. d.
Paid for the liberation of debtors -	0 0 0	21 7 1	25 4 5	0 0 0	5 0 0
Paid to prisoners on their discharge -	1 17 9	1 1 6	11 1 0	3 9 3	2 10 6
Paid gratuities to debtors by order -	2 0 0	3 3 0	4 1 0	0 0 0	0 0 0
Paid for coals for debtors -	0 0 0	0 0 0	2 9 9	9 16 7	0 0 0

Paid rewards to persons who had been discharged, and afterwards obtained certificates of good behaviour -	0 0 0	0 0 0	4 4 0	4 4 0	5 5 0

In this institution, the object has been to combine the two principles of industry * and reflection, and, by the judicious application of solitude in a greater or lesser degree as the specific cases may require, to reform the offenders, so as to restore them to society in an improved state, and encourage them to persevere in a course of industry and virtue.—The attempt has in a great measure succeeded.

In the last six years there have been but as many instances of offenders having been a second time committed to prison; viz. one for felony, two for petty larceny, one for an assault, one for leaving his family chargeable, and one for returning unlawfully to her parish after an order of removal. Of those who have been discharged, twenty-seven have entered into the sea service, nine into the land service; and thirty-five are known to be, at this time, maintaining themselves and their families by honest industry. This would probably be found to have been the case with many more, who are strangers to the county, if information were obtained of their present residence and situations in life.

HOUSE OF INDUSTRY, a house of reception for paupers,

who either from advanced age, or the want of talents, health, strength, or even of inclination, are unable to procure a livelihood by their exertions elsewhere. The following extract from an account of an incorporated house of industry, for two united hundreds, in the county of Norfolk, by Edward Parry, esq. appears in the Reports of the Society for bettering the Condition of the Poor.

“The house of industry, for the hundreds of Mitford and Launditch, in the county of Norfolk, was established and incorporated by act of parliament in the year 1775. These hundreds contain 32 parishes; two of them large market-towns, but without manufactories. This house of industry certainly has the merit of being managed with great attention to the health, comfort, and (in some degree) to the morals of the poor. I speak of it (says Mr. Parry) from experience, having been an active director of it for 13 years, during my residence in the county of Norfolk. The following is the plan on which it is conducted.—There is a large building which contains on an average about 500 persons of all ages; and there is an hospital, about a quarter of a mile from the house,

* Upon examining the general produce of labour, in a workhouse or house of correction, it should seem that there is something in the name, the air, the situation, or in the system of them, that pallies the power of human industry, and reduces the energy of a strong vigorous man to a level with that of an helpless child. Mr. Bernard, however, states an exception, equally honourable to the individual, to the magistrates, and to Mr. Ayres, the governor of the Middlesex house of correction, in Cold-Bath-Fields.—In February, 1797, a person was committed to that house for a twelvemonth, on account of his concern in a fraudulent transaction, which he had been drawn into by a combination of artful Jews; and, in the progress of which, he had been stripped of nearly all his own property. He was a smith, and a very excellent workman. With permission of the magistrates, Mr. Ayres, the governor, fitted him up a forge, and employed him to repair the locks of the house, which are 800 in number, and were got into bad condition. The locks are, of necessity, large, and of an expensive construction. In the course of eleven months, ending on the 8th of February, 1798, he cleaned and put in order all the locks in the prison, so completely, that they are now better than when they were first put on. During those eleven months, he has, by his own wish, extended his working hours beyond those of the other prisoners. He had sometimes the assistance of a person to blow his bellows; but he has compensated for this by doing a good deal of other work in the house, besides repairing locks. The whole, therefore, of that work may be fairly placed to his own account. Estimating what he has done, at a lower rate than the county smith has ever charged to the house, his eleven months' work amounts to the sum of 160l. 12s. On the time of his confinement being expired, the magistrates ordered him a donation of 30l. out of the produce of his work. He then said, that he had received such ill treatment in the world, and had experienced such kindness and real friendship in that place, from the governor of the house, that, if he could maintain his wife and two children decently by his labour, he would pass the remainder of his days there. An apartment has, in consequence, been fitted up for him and his wife; his two children being placed in a charity-school: he is appointed the county smith, and she the inspectress of the female prisoners, with a salary perfectly satisfactory to them both.—I am favoured with this account by the Rev. Dr. Glasse.

in which the sick are kept separate, according to their different disorders. They have a governor and matron, to which appointments, by preference, a man and wife are elected; and they have apartments in the house, where they must constantly reside. The former has £60. a-year, the latter £25; and they have coals, candles, and washing. There is a chaplain, who is generally a neighbouring clergyman, and has a salary of 30l. a-year; his duty is to read prayers once every day, and preach on Sundays. There is also a surgeon, who has 60l. a-year; he is a resident of one of the neighbouring market-towns; but must attend every day, and has an apothecary's shop in the house, the medicines being found by the corporation.

"There are also four surgeons for the out districts of the hundreds; who for attendance and medicines are allowed 45l. a-year each, and attend all casualties, and report the state and condition of the patient and his family to the next committee. The director's clerk, who is always an attorney, has 50l. a-year; he attends all committees and meetings. There must, by the act of parliament, be 36 directors, and 24 guardians. Every person, having a freehold estate of 300l. a-year, and being resident in the district, is compelled to be a director, and to act as such; and, in case there are not enough of that description, the deficiency to be made good out of resident freeholders of 150l. a-year (in which all rectors of livings of that value are included), until the whole number of directors is completed.

"The guardians are chosen by ballot, annually, out of the farmers who rent 100l. a-year and upwards, or persons having estates of that value. There is an annual meeting, and three quarterly meetings, of the directors and guardians, at one of the inns at the town of Dereham. At the annual meeting, which must be in the month of June, the directors and guardians are formed into twelve committees by ballot; three directors and two guardians being to attend, every month, at the house of industry, on each Tuesday, from ten o'clock in the forenoon, till three, four, and sometimes five o'clock in the afternoon; for the purpose of visiting, and inspecting the state of the house and the governor's accounts; of receiving reports from the overseers of the parishes, signed by the surgeons of the district, as to the state and condition of the sick poor in the several parishes—and of granting them temporary relief—and also of directing that employment may be found for such as apply for it.

"There is a farm of about 150 acres of land, belonging to the house, and kept in hand and managed by the governor; this provides a dairy, and occasionally fats a few oxen and sheep: there is likewise a garden of six or seven acres; which is cultivated by the old men of the house, and produces an abundant supply of vegetables. The governor purchases the wheat, at market, from harvest till March or April, for the whole year: it is ground into meal by a mill belonging to the house; and is made into bread, unsifted even from the bran, a kind of bread commonly eaten in all farmers', and most gentlemen's houses, in Norfolk.

"All the meat is purchased in the animal, and killed in

the house. There are several manufactories established in the house; and all articles of their wearing apparel are made by the poor themselves; the whole establishment being managed with economy, but with sufficient plenty.

"From this account it may be supposed that the poor of those hundreds are upon the whole well taken care of, and made comfortable in their old age; at the period when their labour is over.

"And it is certainly true that those in the house are, generally speaking, well lodged, fed, and clothed: but, when it is considered that these five hundred people are, or are presumed to be, merely paupers, it will appear that there must remain a large class of industrious poor, who only want assistance occasionally, being generally employed. As to those with large families, the mode is to relieve them, by taking some of their children into the house: but I have known many parents, who, rather than consent to this, have half starved themselves and their children; and sometimes carried it so far, that, by reducing themselves too low, they have been at length obliged to leave their cottage, and to be carried altogether to the house of industry; the man's spirit broken, and he himself (if he has stamina left to recover) becoming a burthen all his life; as he seldom returns out of the house, capable of the same industry and exertion that he possessed before he went in.

"It is further to be observed, that as the farmers pay a certain and limited rate to the corporation, which cannot be raised, they care very little about the poor; and they frequently send whole families into the house, who might with the little assistance support themselves out of it. Besides this, the separation of their children from them, destroys all natural affection, and often occasions a wish that it would please God to take the child, instead of their being compelled to send it into the house of industry.

"Of the 500 persons in the house, about half are children under 14 years of age. At that age, the children are ballotted on the farmers or tradesmen (keeping servants)* for one year; who are compelled by the act of parliament to take them, or pay 10l.; but at the end of that year it happens that many return to the house of industry, unable to get another place; being found too delicate to perform that service, which the farmer gets from those whom he hires out of cottages; and in consequence, many of them become fixed to the house for life.

"The other half consists of profligate men, who, through idleness and debauchery, have reduced their families to depend on the establishment for their support;—disolute wenches, who come to lie-in of bastard children, or to be cured of bad diseases;—and (with these) the honest industrious poor, who, after many years of hard labour or long service, can no longer provide for themselves; and are then of necessity driven from their peaceful cottages to a society, which must disgust and distress them the remainder of a life, the preceding part of which has been usefully employed in the service of the community.

"The above are part of the many objections to institutions

* The benefit of parishes placing out young persons in service, though only for a year, is, that it soon makes them fit for service in other parishes, and relieves their own parish from any further burthen. The compulsory binding of poor children under the statute law, till the age of twenty-one, is liable to this objection; that the master is not likely to use his apprentice so well, or the apprentice to serve his master so diligently, as if the contract was of shorter duration, and by mutual consent. Mr. Adam Smith is of opinion, that even in trades, or what he terms *skilled labour*, long apprenticeships are unnecessary and prejudicial to industry; and he gives powerful reasons for his opinion (vol. i. p. 184—102): but whatever may be the case as to trades, surely to bind a young lad, from fourteen years of age to twenty-one, to husbandry, or service, merely because he is out of work at the time, is a harsh and violent measure, and must have a tendency to check industry and exertion. In the house of industry, which is the subject of Mr. Parry's paper, children cannot be bound to husbandry for a longer term than three years.

of this sort: and I confess that, after having attentively considered the subject some years, I think if workhouses of any kind shall be deemed useful (which I do not hold to be the case, except perhaps in cities and large towns), the best plan is to unite three or four, or at most six parishes; which shall have a small new-built house, planned on purpose, merely as an asylum for the aged and infirm; to be superintended by the gentlemen and farmers who reside in the parishes; and to be subject to the inspection and control of the magistrates acting for the division in which they are situated. That all the poor capable of work, though requiring occasional relief, either on account of bodily infirmity, or of large families, should receive it at their own houses; and in general in clothes, or other necessaries in preference to money. It is well known that the present wages do not enable a labourer to support several small children during the period that they are incapable of labour. I therefore think he should be allowed one shilling per week with every child above three, who shall be under the age of twelve years; and that when these children are to enter upon a service, they should always be clothed by the parish. This latter article is almost universally followed at the house of industry, which I have before mentioned. It was adopted, about eight years ago, on my recommendation: at first it met with many opponents; but is, I believe, now considered by all the directors and guardians as a very great stimulus to the parents to get them services, and thereby to preclude them from afterwards being any burthen to the parish.

"In general, workhouses are very improperly so called; being mostly filled with aged and infirm poor, who are considered as past work; or with idle profligate wretches, whom the overseers suffer to live in filth and inactivity, rather than complain to a magistrate to have them compelled to labour, or than to offer them any employment, whereby a part of their maintenance might be obtained. This state of the workhouse being known throughout the parish, the honest and industrious labourer, who has brought up a large family with credit, and who from misfortune is poor, and from age past his labour, will rather submit to be half starved, than take up his abode amidst such wretchedness and profligacy; although he knows the overseer will give him no relief out of the house. This, I am sorry to say, I have found to be the case; and in one instance, upon hearing such a declaration from a poor man, a gentleman, who acted in the same division as myself, went with me unexpectedly to visit a parish workhouse; where we found men, women, and children, of different families, crowded together, nineteen persons in two rooms of twelve feet square, and little more than six feet high.

"Children should on no account be put into workhouses*, if they have parents or relations who will take care of them; although it be requisite to give some allowance, and even to the full of what they would cost in the workhouse. Experience proves that children brought up in cottages, half naked, and indifferently fed, make harder and better labourers, than those in parish workhouses. This I have seen demonstrated in houses of industry, where though the children are taken early from their parents, well clothed and well fed during their con-

tinuance in the house, and though they generally look healthy, yet they become so delicate, as to be unfit for husbandry labour, in a farmer's service; and are frequently a heavy expence to their employer, from disorders they contract, when taken from warm work-rooms, and exposed to field employments in winter.

"It is however to be observed, that one general system cannot be adopted in all cases; and that, in large manufacturing towns, houses of industry, well managed, may still be desirable, because the children, being brought up to sedentary employments, will be thereby accustomed to the habits of life which they will in all probability be induced to follow.

"One great advantage Norfolk has long derived from the custom of putting out all work by the piece, thrashing by the quarter, &c. (and which is making its way to other counties), is, that the father takes his sons to the field as soon as they can handle a hook, or raise a mattock; and they soon earn their living, besides being at an early age inured to industry and weather.

"I think every thing should be done to give the labouring man an idea, that he has an interest in the prosperity of the parish he lives in; and that his children will be taken care of, if death, or misfortune, prevent his ability to do it. The two great points are, first, to provide employment for all the poor, while able to work: secondly, to encourage, by every unexceptionable mode, friendly societies, or purse clubs; that, when their labour is over, they may look forward to a comfortable support, without the dreary prospect through life, of a workhouse, to end their days neglected by their relations, perhaps at a distance from them; and where every morsel of victuals is often grudged them by an abusive overseer, or by a man who has farmed them at so much per head."

Houses of industry are too frequently undervaluing of the name, from a want of superintendency; and hence they have acquired the quaint names of *poor-house*, or *work-house*, denoting rather what is expected than what is performed. It may be seen, however, under the article DUBLIN (*Supp.*), that these institutions are capable of considerable amelioration; and this will be still more evident on perusing the following extract from a further account of the improvements in the house of industry in Dublin, by the Right Hon. Thomas Pelham.

The acting governors of the house of industry in Dublin, have made a second report of their proceedings, by which it appears that (notwithstanding the confusion which must necessarily have attended the rebellion in Ireland, during great part of the summer) the zeal, the activity, and the diligence of the governors of this institution have not abated; but that improvements, which they had commenced and suggested in the preceding year, have been confirmed and realized in the last. They have stated to the parliament of Ireland, the means by which they have encouraged the industry, and increased the comfort, of those who have been confined to their care.

They have augmented the former allowance of 2d. in the shilling earned by the poor in the house, to 8d.; and the payment of this quota is in a coin, current only in the house; which has effectually prevented the purchase of spirituous

* The defect of several workhouses is, that many persons are kept there, who could do better for themselves, and with less expence to the parish, out of it. In one, that I have attended to, I found, on visiting it, 53 persons: of these, 13 were above the age of 50; 3 helpless men and women under that age; and 11 children, too young to be placed out in the world: 15 of the remaining 26 were placed out by me in service, or otherwise, in the course of a month; and the other 11 were only kept till places could be found for them.—In this instance it is to be observed that 26 of these 53 persons would have been better out of the workhouse; but the house *had been farmed*; and on that account it had not been the man's interest to put them out, as that would have occasioned some immediate expence; and it might probably have been the cause of his allowance from the parish being reduced at the end of the year, or of his losing his contract by the competition of a lower offer.

linens, and is laid out in extra provisions and clothes, at a shop established within the house, upon the plan of the village shops recommended in a former report of this society. The adult poor have no clothing, but such as they procure by their industry; and they are better clad than formerly.—A workshop with twelve flocking frames has been erected, in which a number of females have been employed; and it is well observed by the governors, “that the employing females in this manufacture, and in others of a like kind, where an expert hand is more requisite than masculine strength, should be encouraged.”

The children of both sexes are apprenticed for seven years, to those who superintend their instruction, with a reservation to the Board, of the power of assigning over their indentures at the end of the two first years, to such manufacturers as shall propose to take them for the remaining five. The persons who instruct the children, have at present a fixed salary. It is intended to give them one-third of the earnings; to lay out one-third in clothing the children, and the remainder to be expended in premiums.—The hospital is open to all the poor of Dublin; and it appears, that, in the year 1798, out of 1,659 patients admitted, 1,443 were restored to health, and to their families; and that of 66 lunatics, 47 have been cured.—The walls of the sick wards are washed every month with lime, and it is purposed to have a detached house exclusively for fevers.

“With a view to better the condition of the poor of Dublin in general, and to prevent the funds of the house of industry from being incumbered by unnecessary claims, the board of governors determined to open a public kitchen, or soup shop, detached from the house of industry.” Their addresses to the public, and their proceedings respecting their public kitchen, are worthy of applause and imitation. The success is proved by the numbers that have been benefited by it: 6,431 persons were supplied with food from this kitchen*, between the 4th day of February, the day of opening, and the 28th of February, the date of their report.

It is to be observed, that this institution differs very materially from any poor-house, or other institution, in Great Britain, both in its object, its government, and its resources. In Ireland there are no poor laws, or local taxes, for the support of the poor. This institution was intended for the purpose of providing employment, and for the maintenance of the poor of Dublin, and for the punishment of the vagrants and beggars who infested the streets of that city. The government was vested by act of parliament in a certain number of public officers; the mayor and aldermen of Dublin, and many other individuals; some of whom were named in the act, and others elected; and considerable grants have been annually made by parliament for its support. The institution certainly did not at first answer the expectation of the public, but fell into discredit.

The statement of these circumstances will render the report of the acting governors more intelligible, and, by explaining their situation, enhance the merit of their exertions.

HOUSE OF RECOVERY, an institution of a very recent description, but of infinite consequence to the preservation of the poor, as will appear from the following account of the

House of Recovery, established by the Board of Health at Manchester, by Thomas Bernard, Esq.

In May, 1796, an house for the *prevention of infectious fevers*, was opened upon private subscription, at Manchester, by the Board of Health there; and placed under the inspection of a medical committee, consisting of the medical gentlemen of the Infirmary. The following **REGULATIONS** were adopted respecting it:

1st. That the physicians of the Infirmary shall be authorized to give one or two shillings from the funds of this institution (by a ticket to the secretary of the Board of Health) to the person who shall furnish the earliest information of the appearance of fever in any poor family, within the limits of their respective districts.

2d. That as soon as the secretary has received this ticket, he shall apply, or take care that application be made, to some trustee of the Board of Health, living within the district, and who is a subscriber to the infirmary, for an immediate recommendation of the sick person as a home patient.

3d. That such patients as the physicians shall deem peculiar objects of recommendation, either on account of their extreme poverty, or of the close and crowded state of their habitations, shall be conveyed in a sedan chair (provided with a moveable washing lining, and kept for the sole purpose, and distinguished by proper marks) to the House of Recovery.

4th. That the physicians shall be requested to form the necessary regulations for the domestic government of the families of the home patients, afflicted with fever.

5th. That a reward to the amount of £1 shall be given to the heads of the family, after the cessation of the fever, on condition that they have faithfully observed the rules prescribed for cleanliness, ventilation, and the prevention of infection, amongst their neighbours. This reward shall be doubled in cases of extraordinary danger, and when the attentions have been adequate and successful.

6th. That, after the visitation of fever has ceased in any poor dwelling-house, the sum of £1 or a sufficient sum, shall be allowed (to be expended under the direction of an inspector) for white-washing and cleansing the premises, and for the purchase of new bed-clothes, or apparel, in lieu of such as it may be deemed necessary to destroy, to obviate the continuance or propagation of fever.

7th. That an inspector shall be appointed in each district of the Infirmary, to aid the execution, and to enforce the observance of the foregoing regulations. And that the gentlemen of the Stranger's Friend Society shall be requested to undertake this office.

The following are the *Internal Regulations* for the House of Recovery:

1st. Every patient, on admission, shall change his infections for clean linen; the face and hands are to be washed clean with lukewarm water, and the lower extremities fomented.

2d. The clothes brought into the house by patients, shall be properly purified and aired.

3d. All linen and bed-clothes, immediately on being removed from the bodies of the patients, shall be immersed in cold water before they are carried down stairs.

* A public kitchen had been previously tried with success at Cork; (see *CORK, Supp.*). The distribution made at Dublin, amounted to 12 ounces of bread and a quart of soup; which was given *gratis* to any poor person who applied, and who was not in receipt of relief from the House of Industry. Inconveniences, however, had attended the mere donation; and in truth, that which is indiscriminately given is never duly valued. It was thought better that the soup and bread should be sold at a reduced price; so that the poor might receive it by tickets given them by their more opulent neighbours, and that the working mechanic might be supplied at a very moderate rate; that of two pence for half a pound of bread and a quart of soup. This has been accordingly done.

4th. All discharges from the patients shall be removed from the wards without delay.

5th. The floors of the wards shall be carefully washed twice a-week, and near the beds every day.

6th. Quick-lime shall be flaked in large open vessels, in every ward, and renewed whenever it ceases to bubble on the affusion of water. The walls and roofs shall be frequently washed with this mixture.

7th. No relation or acquaintance shall be permitted to visit the wards, without particular orders from one of the physicians.

8th. No strangers shall be admitted into the wards; and the nurses shall be strictly enjoined not to receive unnecessary visits.

9th. No linen or clothes shall be removed from the House of Recovery, till they have been washed, aired, and freed from infection.

10th. No convalescents shall be discharged from the house, without a consultation of the physicians.

11th. The nurses and servants of the house shall have no direct communication with the Infirmary; but shall receive the medicines in the room already appropriated to messengers from the home patients.

12th. The committee of the Stranger's Friend Society shall be requested to undertake the office of inspecting the House of Recovery.

13th. A weekly report of the patients, admitted and discharged, shall be published in the Manchester newspapers.

14th. When a patient dies in the wards, the body shall be removed as soon as possible, into a room appropriated to that use; it shall then be wrapped in a pitched cloth; and the friends shall be desired to proceed to the interment as early as is consistent with propriety.

15th. All provisions and attendance, for the patients in this House of Recovery, shall be provided from the funds of this institution, without any communication with the Infirmary.

The circumstances of the first patients, removed to the House of Recovery, all tended to prove the truth of the position, that the most contagious and destructive fevers, by which manufacturing and other crowded towns have been afflicted, had proceeded from *individual infection*; and that if, upon the appearance of the fever, the poor patient had been removed to a clean well ventilated room, and dismissed after recovery with clothes properly purified, much disease and misery would have been prevented, and many lives saved.

As the statement of the circumstances of the first patients that were admitted into the House of Recovery, may tend to shew the sufferings of the poor, where no house of recovery is prepared for them, we here state them from the physician's reports inserted in the Minutes of the Board of Health.

"Mary Parkinson, aged 20, the second daughter of Ann Parkinson, lodging with her mother and sister, at James Rushton's (who rents a garret, No. 50, Great Turner-street), was seized on the 17th instant with a spotted fever, and visited in a day or two after, as a home patient of the Infirmary.

"She was found almost destitute of covering, lying upon a collection of rags spread upon the floor of a close, dirty, and noisome garret. In this wretched substitute for a bed, the mother and another grown-up daughter (just recovering of fever) likewise slept. In an opposite corner of the room, James Rushton, his wife, and three children, slept upon a bed, similar to that above described. Under such circumstances, I was fully convinced, that it would be impracticable to prevent the fever from spreading, unless the infected person could be removed. But, as the House of Recovery was not then opened, the removal of the patient could not be effected. In a day or two, as I expected, the daughter of James Rushton

sickened, and became dangerously ill of the fever. As the wife (who was far advanced in her pregnancy), and the rest of the inhabitants of the room, might be supposed to be in hourly danger of infection; I proposed, therefore (the House of Recovery being now ready), as the most likely method of saving the lives of the two women so dangerously affected, and of preventing the rest from receiving the infection, that the sick persons should be instantly removed into the House of Recovery. With every expression of joy and gratitude, the parents of both the patients accepted the offer, and they were accordingly removed without suffering any injury, or apparent inconvenience, by the removal.

"Mary West, the wife of a soldier belonging to the Manks Fencibles, was infected with fever from attending her husband, who had recovered, and was ordered to join the regiment.—She had been driven out of doors upon the symptoms of fever appearing, and was refused admittance wherever she applied. In consequence of exposure to cold, and distress of mind, her complaint rapidly increased, and she got a recommendation as in-patient to the Infirmary. But the rules of this charity forbade her admittance. She was, therefore, received into the House of Recovery, as an object peculiarly claimed by the nature of the institution.

"Jeremiah Bowcock was removed, on the first appearance of fever, from a family living at No. 74, Newton-lane; and, besides himself, consisting of seven men, four women, and three children. On the same floor with, and adjoining to the chamber (at No. 78, Newton-street) in which he and three others slept, a man, his wife, and three children, constantly reside. The ground floor is occupied by two men, one woman, and three children; and the cellars are let for work-rooms. The disease was introduced into his house by Bowcock's brother, who had been turned into the streets, when labouring under typhus, by the persons with whom he lodged.—Immediately after the removal of this patient, the room in which he had been confined was duly washed and ventilated; and means were taken to dis-infect the clothes and bedding, by a free exposure of them in the open air.

"Margaret Billington, wife of a private in the York Fencibles, was removed on the 10th day of her disease, from a small room, at No. 8, Pump-street, which has been for some time the nightly abode of four grown persons, and three children. On her removal, the bedding was exposed to the air, in an open space, for several hours; the floor of the apartment was scoured; the walls were white-washed; fumigations with nitrous gas were employed, according to the practice of his majesty's naval hospitals; and a reward was promised to the heads of the family, provided their endeavours to extinguish contagion were attended with success.

"John Owen, Robert Williams, and William Williams, from a house in Salford, where six persons lay ill of a fever at the same time, in two very small rooms. One patient only remains in that house, who is now recovering.

"William Lomax, a child from a house in Longworth-street, where a family of five persons had only one bed-room for their accommodation. The eldest daughter was first taken ill; after the recovered, the father, mother, and this boy, were all seized with the fever together. The father died. The mother miscarried, from grief and fatigue, the day after his death. A younger daughter has since been taken ill, and will be admitted as soon as possible.

"Samuel Gould, from a large family with whom he lodged. His fever is of a very dangerous nature, and it is hoped that, by his removal, the infection of the whole family will be prevented."

The beneficial effects of the House of Recovery, even after a year and a half, are almost beyond belief. The facts are, how-

ever, established by authentic documents.—The number of fever patients (as entered in the physician's book at the Infirmary) in Portland-street, Silver-street, and the other streets in that pile of buildings, in the neighbourhood of the House of Recovery, for the two preceding years and eight months, were 1,256, something more than the average of 400 a-year:—those in the same district from July, 1796 (a period commencing two months after the establishment of the House of Recovery), to July, 1797 (being twelve months), were only twenty-six;—of these, there were, in July, 1796, only five such patients; in August, but one; in September, 1796, none; and in the four last months, from March to July, 1797, only one fever patient.

In the report of the weekly board of the Infirmary at Manchester, notice is taken of the extraordinary effects of the House of Recovery, in diminishing the proportion of the fever patients in the Infirmary. It appears from the physician's books of the Infirmary, that in January, 1796 (before the establishment of the House of Recovery), the whole number of the home patients at the Manchester Infirmary was 296, of which 226 were cases of fever: and that in January, 1797, the number of their home patients was 161; and, of these, only 57 were cases of fever.

From the opening of the House of Recovery, on the 19th of May, 1796, to the 2d of November, 1797, 542 fever patients have been admitted. Of these, 465 have been cured and sent home; 48 (and these were some very bad cases) have died; and 29 were, on the 2d instant, remaining in the house. The account, therefore, up to the 2d instant, stands thus:

Cured and discharged	-	-	465
Dead	-	-	48
Remaining in the house	-	-	29

Total admitted - 542

But the proportional number of cures in the last half-year (a benefit that will probably increase) is greater than that of the preceding period; because the poor are now induced to apply in the earlier stages of the fever, when medicine can be applied with more effect. The account from the 8th of May, 1797, to the 2d instant, being near six months, is as follows:

Cured and discharged	-	-	141
Dead	-	-	8
Remain in the house	-	-	29

Total - 178

Many of the opponents of the House of Recovery in Manchester* are become its active friends; and that, which was at first an act of philanthropy in a few individuals, is now supported by the good wives and contribution of the greater part of the respectable inhabitants at Manchester. Other consequences have attended the extraordinary success of this institution:—viz. first, that the Board of Health does now receive fever patients into the house from places beyond the

districts for which it was first established; by which means the environs of the town will be cleared of the epidemic fever: secondly, that the Infirmary also receives a variety of patients, which they were obliged to refuse, when the Infirmary and town were oppressed by the enormous crowd of fever patients, whose claims seemed to supercede those of persons not afflicted with contagious diseases: and thirdly, that in the year 1796, there was a decrease of near 400 in the bills of mortality at Manchester.

It may be observed, in conclusion, that a Board of Health and a House of Recovery, upon the plan of that at Manchester, would be useful in all towns; but particularly where the poor, employed in manufactures, are incapable of receiving proper medical relief, in their own confined habitations; and where they are peculiarly liable to communicate contagion, not only to their own family, and to those who dwell under the same roof, but to the neighbourhood. A Board of Health, to prevent the spreading of contagious diseases among the poor, is peculiarly applicable to a populous town: but it is not exclusively so. It would be very useful in country villages and country neighbourhoods, to assist and stimulate the overseers in that part of their duty which relates to the health of the poor, and to prevent the progress of infectious disorders. It is peculiarly in the prevention of disease and contagion, that the benefit returns with increase upon the benefactor, and that the merciful receive mercy.

A subsequent report from the Society for bettering the Condition of the Poor, acquaints us, that in August, 1798, there were 19 patients in the house. Their apartments appeared to be as airy, as clean, and as comfortable as could be wished. The upper floors are laid together, so as to form four large wards; and each of the front rooms below will contain two beds, so as to accommodate in the whole 28 patients conveniently. The rooms on the ground floor are appropriated to the convalescents; and to the use of the servants, who consist of a head nurse and three other nurses; occasional assistance being hired, when necessary. The wards are furnished with iron bedsteads, without curtains, and with ticks filled with straw, which is changed at proper periods. The mode of removing the sick into the house is in a sedan-chair, kept in an out-building for that purpose.

When patients are admitted into the house, a flannel dress is provided for them, and their own clothes are carried into the yard, to be washed, scoured, and ventilated. During their convalescence they wear the dress of the house; which consists of a jacket and trowsers for the men, and of a wrapping gown and petticoat for the women. Part of a vacant piece of ground, adjoining to the houses, is enclosed with a wall for the purpose of washing and airing the clothes of the patients. At the time of discharging them their own clothes are returned to them perfectly clean, and they rejoin their families, and resume their occupations, without the hazard of communicating infection to others.

To fo great a degree have contagious fevers been reduced †, since the establishment of the House of Recovery, that the limits

* Similar establishments have been successfully made in London, Chester, Stockport, Liverpool, and some other places in England, and at Waterford, in Ireland. For a detail of the principles and rules to be adopted in country towns, to check the progress of disease and infection, the reader is referred to a very excellent pamphlet by the Rev. Sir William Clerke, bart. rector of Bury in Lancashire, published by Johnson, St. Paul's Church-yard; and also to a tract on the same subject by the late Dr. Murray, who has recently fallen a sacrifice to his zeal and activity, in promoting the views of the Society for bettering the Condition of the Poor, in this respect.

† In the former report it was stated the extraordinary diminution that had taken place in the bills of mortality at Manchester, since the opening of the House of Recovery. An additional proof, of a singular nature, appears in the last year's accounts of the overseers of the poor; in which the charge for deceased paupers' codlins is 100l. 10s. It used to be half as much again.

of the house are now extended to the whole of Manchester and its extensive suburbs, and to every part of the vicinage, for two miles round, from whence a fever patient can be safely removed. The number of home patients of the infirmary at Manchester has also, in consequence, been gradually diminished. There were admitted on the physicians' books during the year, ending 1st June, 1796 2880

Ditto in the year ending June, 1797, being the first year of the house of recovery being opened 1739

Ditto in the year ending June, 1798, 1564

During the spring and summer of the preceding year, contagious fevers of an alarming nature had appeared in different parts of the town and neighbourhood. By removing, however, the patient into the House of Recovery, the extension of the fever was in every instance prevented. The account of the house for one year, ending the 31st of May, 1798, at which time 710 patients had been admitted, is as follows:

Cured and discharged	300
Dead	16
Remained then in the house	23

Account for another Year, to 31st May, 1799.

Cured and discharged	364
Dead	24
Remained in the house, 31st May, 1799	11

To a poor creature who has been languishing in a cold, damp cellar, or in a garret exposed to the injuries of the weather, amidst the neglect and confusion of a wretched family, —to such a patient a clean bed, a quiet ward, an attentive nurse, and the frequent visits of the physician, are of most potent efficacy. To these causes it must be imputed that, upon a return of the epidemic fever of 1797, of 149 dangerous cases received from the beginning of May to the beginning of October, only four patients died.

Of the benefits of the House of Recovery, it is one of no small consequence, that the owners of cotton mills are now induced to pay a more scrupulous attention to the health of their work-people; and that their buildings are, in general, kept cleaner and better ventilated. A salutary impression has also been made on the minds of the poor, respecting the utility of cleanliness in their houses. The idea of fever comprehends, among them, that of ruin to their circumstances, and desertion by their neighbours. It may therefore be expected, that they will catch at every means within their reach to avoid so dreadful an evil: and when they find that a public charity extends its care to them so far, as to whitewash their houses, when the physicians report it to be necessary, they must feel the propriety of attending more to this object.

HOYER, a town of Denmark, in the duchy of Sleswick, celebrated for its oyster-fishery, four miles W. of Tonderen.

HUBERTSBERG, a town of Upper Saxony, with a magnificent hunting-seat, built by Augustus III. then electoral prince. A peace was concluded here between the kings of Prussia and Poland and the empress queen. It is 22 miles E. of Leipzig.

HUDDESFIELD, a town in the W. riding of Yorkshire, with a market on Tuesday. It is situate near the Calder, amid barren moors, and is the mart for narrow cloths, called plains. It is 42 miles S.W. of York, and 189 N.N.W. of London. Long. 1. 40. W. Lat. 53. 40. N.

HUDICKSWALL, a sea-port of Sweden, in the province of Helsingland, with a good harbour. The inhabitants carry on an advantageous trade in the timber, flax, linen, butter, fish, &c. It is 130 miles N. of Upfal. Long. 18. 36. E. Lat. 61. 48. N.

HUDSON, a city of the United States, in New York,

seated on eminence, on the E. side of Hudson's River, 30 miles S. of Albany, and 130 N. of New York. Long. 75. 20. W. Lat. 42. 23. N.

HUESSEN, a town of Dutch Guelderland, seated on the Rhine, three miles S. of Arnheim.

HUETINBERG, a town of Germany, in Carinthia, eight miles S.W. of Reichenfels.

HUETTA, a town of Spain, in New Castile, 67 miles E. of Madrid. Long. 1. 55. W. Lat. 40. 22. N.

HUPFINGEN, a town of Suabia, in the principality of Furtenburg, four miles N.N.W. of Furtenburg.

HULHEN, a town of Austrian Brabant, nine miles S.E. of Brussels. Long. 4. 37. E. Lat. 51. 44. N.

HUNDSELD, a town of Silesia, seated on the Wide, eight miles N.E. of Breslaw. Long. 17. 18. E. Lat. 51. 9. N.

HUNDRUCH, a district of Germany, in the circle of Upper Rhine, situate between the Rhine, the Moselle, and the Nahe; belonging partly to the elector of Treves, the elector palatine, and the prince of Hesse.

HUNGEN, a town of Germany, in the circle of Upper Rhine, and county of Solms Braunsfels, 14 miles S.E. of Wetzlar.

HUNMANBY, a town in the E. riding of Yorkshire, with a market on Tuesday, 34 miles N.E. of York, and 209 N. of London. Long. 0. 12. W. Lat. 54. 12. N.

HUNTER (John), a celebrated physiologist, was the youngest child of John Hunter, of Kilbride, in the county of Lanark. He was born on the 14th of July, 1728, at Long Calwood, a small estate belonging to the family. His father dying when he was about ten years of age, though he attended the grammar-school he made no progress in learning; and may be said to have been almost totally illiterate when, in September 1748, he arrived in London. His brother, Dr. William Hunter, was then celebrated as a teacher of anatomy, and John had expressed a desire to assist him in his researches. Accordingly, he had here every opportunity of improvement, as all the dissections at this time carried on in London were confined to that school.

In the summer 1749, Mr. Cheselden, at the request of Dr. Hunter, permitted him to attend at Chelsea Hospital; and he there learned the first rudiments of surgery. The following winter he was so far advanced in the knowledge of human anatomy, as to instruct the pupils in dissection, to whom Dr. Hunter had very little time to pay attention. This office, therefore, fell almost entirely upon him, and was his constant employment during the winter season. In the summer months of 1750, Mr. Hunter attended the hospital at Chelsea; in 1751, he became a pupil at St. Bartholomew's, and in the winter was present at operations occasionally, whenever any thing extraordinary occurred. The following summer he went to Scotland; and in 1753 entered, it is difficult to conceive for what reason, as a gentleman commoner at St. Mary-hall, Oxford. In 1754 he became a surgeon's pupil at St. George's Hospital, where he continued during the summer months; and in 1756 was appointed house-surgeon. In the winter 1755, Dr. Hunter admitted him to a partnership in his lectures, and a certain portion of the course was allotted to him; besides which, he gave lectures when the doctor was called away to attend his patients.

Anatomy and physiology seem to have been pursuits for which Mr. Hunter's mind was peculiarly fitted, and he applied to them with an ardour and perseverance of which there is hardly any example. His labours were so useful to his brother's collection, and so gratifying to his disposition, that although in many other respects they did not agree, this simple tie kept them together for many years.

Mr. Hunter employed himself for ten years on human anatomy, during which period he made some addition to that knowledge. He traced the ramifications of the olfactory nerves upon the membranes of the nose, and discovered the course of some of the branches of the fifth pair of nerves. In the gravid uterus, he traced the arteries of the uterus to their termination in the placenta. He was also the first who discovered the existence of the lymphatic vessels in birds.

Many parts of the human body being so complex, that their structure could not be understood, nor their uses ascertained, Mr. Hunter was led to examine similar parts in other animals, in which the structure was more simple, and more within the reach of investigation; this carried him into a wide field, and laid the foundation of his great collection in comparative anatomy. This active enquirer began with the more common animals, and preserved such parts as appeared by their analogy, or in some other way, to elucidate the human economy.

In 1760 his health was so much impaired by excessive attention to these pursuits, that he was advised to go abroad, having complaints in his breast, which threatened a consumption. Mr. Adair, inspector-general of hospitals, appointed him surgeon on the staff; and in the following spring he went with the army to Belleisle, leaving Mr. Hewison to assist his brother during his absence.

Mr. Hunter served, while the war continued, as senior surgeon on the staff, both in Belleisle and Portugal, till the year 1763; and in that period acquired his knowledge of gun-shot wounds. On his return to England he settled in London; where, not finding the emoluments from his half-pay and private practice sufficient to support him, he taught practical anatomy and operative surgery for several winters. He returned also, with unabated ardour, to comparative anatomy; and as his experiments could not be carried on in a large town, he purchased for that purpose, above two miles from London, a piece of ground near Brompton, at a place called Earl's Court, on which he built a house. In the course of his enquiries, this excellent anatomist ascertained the changes which animal and vegetable substances undergo in the stomach when acted on by the gastric juice; he discovered, by means of feeding young animals with madder (which tinges growing bones red), the mode in which a bone retains its shape during its growth; and explained the process of exfoliation, by which a dead piece of bone is separated from the living.

On the 5th of February, 1767, he was chosen a fellow of the Royal Society. His desire for improvement in those branches of knowledge which might assist in his researches, led him at this time to propose to Dr. George Fordyce, and Mr. Cumming, an eminent mechanic, that they should adjourn from the meetings of the Royal Society to some coffee-house, and discuss such subjects as were connected with science. This plan was no sooner established, than they found their numbers increased; they were joined by Sir Joseph Banks, Dr. Solander, Dr. Maskelyne, Sir George Shuckburgh, Sir Harry Englefield, Sir Charles Blagden, Dr. Nooth, Mr. Ramdén, Mr. Watt of Birmingham, and many others. At these meetings discoveries and improvements in different branches of philosophy were the objects of their consideration; and the works of the members were read over and criticised before they were given to the public. It was in this year that, by an exertion in dancing, after the muscles of the leg were fatigued, he broke his tendo Achillis. This accident, and the confinement in consequence of it, led him to pay attention to the subject of broken tendons, and to make a series of experiments to ascertain the mode of their union.

VOL. X.

In the year 1768, Mr. Hunter became a member of the corporation of surgeons; and in the year following, through his brother's interest, he was elected one of the surgeons of St. George's Hospital. In May 1771, his Treatise on the Natural History of the Teeth was published; and in July he married Miss Home, a daughter of the surgeon to Burgoyne's regiment of light horse. After his marriage, his private practice and professional character advanced rapidly, and though his family began to increase, he still devoted much of his time to the forming of his collection, which, as it daily became larger, was also attended with greater expence. The whole suite of the best rooms in his house were occupied by his preparations; and he dedicated his mornings, from sunrise to eight o'clock (the hour for breakfast), entirely to his pursuits. To these he added such parts of the day as were not engaged in attending his patients.

The knowledge he derived from his favourite studies, he constantly applied to the improvement of the art of surgery, and omitted no opportunity of examining morbid bodies; from which he made a collection of facts which are invaluable, as they tend to explain the real causes of symptoms, which during life could not be exactly ascertained, the judgment of the practitioner being too frequently misled by theoretical opinions, and delusive sensations of the patients.

In the practice of surgery, where cases occurred in which the operations proved inadequate to their intention, he always investigated, with uncommon care, the causes of that want of success; and in this way detected many fallacies, as well as made some important discoveries, in the healing art. He detected the cause of failure, common to all the operations in use for the radical cure of the hydrocele, and was enabled to propose a mode of operating, in which that event can with certainty be avoided. He ascertained, by experiments and observations, that exposure to atmospheric air simply, can neither produce nor increase inflammation. He discovered in the blood so many phenomena connected with life, and not to be referred to any other cause, that he considered it as alive in its fluid state. He improved the operation for the fistula lachrymalis, by removing a circular portion of the os unguis instead of breaking it down with the point of a trochar. He also discovered that the gastric juice had a power, when the stomach was dead, of dissolving it; and gave to the Royal Society a paper on this subject, which is published in the Philosophical Transactions.

In the winter 1773, he formed a plan of giving a course of lectures on the theory and principles of surgery, with a view of laying before the public his own opinions upon that subject. For two winters he read his lectures *gratis* to the pupils of St. George's Hospital; and in 1775, gave a course for money upon the same terms as the other teachers in the different branches of medicine and surgery. But giving lectures was always particularly unpleasant to him; so that the desire of submitting his opinions to the world, and learning their general estimation, were scarcely sufficient to overcome his natural dislike to speaking in public. He never gave the first lecture of his course without taking 30 drops of laudanum to take off the effects of his uneasiness.

Comparative anatomy may be considered as the pursuit in which Mr. Hunter was constantly employed. No opportunity escaped him, as is evident from the various accounts of the peculiar structure of different animals published in the Philosophical Transactions.

In January 1776, Mr. Hunter was appointed surgeon-extraordinary to his Majesty; and in the spring he gave to the Royal Society a paper on the best mode of recovering drowned persons.

In the autumn he was taken extremely ill, and the nature

of his complaints made his friends, as well as himself, consider his life to be in danger. When he reflected upon his own situation, that all his fortune had been expended in his pursuits, and that his family had no provision but what should arise from the sale of his collection, he became very solicitous to give it its full value, by leaving it in a state of arrangement. This he accomplished with the assistance of Mr. Bell, an ingenious draughtsman who resided in his house, and his brother-in-law, Mr. Home.

In 1781 he was elected a fellow of the Royal Society of Sciences and Belles Lettres at Göttingen. And in 1782 he gave the Royal Society a paper on the Organ of Hearing in Fish. Besides the papers which he presented to that learned body, he read six Croonian lectures upon the subject of Muscular Action, for the years 1776, 1778, 1779, 1780, 1781, and 1782. In these lectures he collected all his observations upon muscles, respecting their powers and effects, and the stimuli by which they are affected; and to these he added Comparative Observations upon the moving Powers of Plants. These lectures were not published in the Philosophical Transactions, for they were withdrawn as soon as read, not being considered by the author as complete dissertations, but rather as materials for some future publication.

In 1783 he was chosen into the Royal Society of Medicine and the Royal Academy of Surgery in Paris; and the same year the lease of the house which he occupied in Jermyn-street having expired, he purchased the lease of a large house on the east-side of Leicester-square, and the whole lot of ground adjoining to Castle-street, on which there was another house. In the middle space between the two houses, he erected, at the expence of 3000*l.* a building for his collection; though, unfortunately for his family, the lease did not extend beyond 24 years.

In the building formed for the collection there was a room fifty-two feet long, by twenty-eight feet wide, lighted from the top, and having a gallery all round, for containing his preparations. Under this were two apartments; one for his lectures, and the other, with no particular destination at first, but afterwards made use of for weekly meetings of medical friends during the winter. To this building the house in Castle-street was entirely subservient; and the rooms in it were used for the different branches of human and comparative anatomy.

About this period Mr. Hunter may be considered as at the height of his surgical career; his mind and body were both in their full vigour. His hands were capable of performing whatever was suggested by his mind; and his judgment was matured by former experience. Instances of his extraordinary skill are numerous and well known.

Among other important discoveries, was a new mode of performing the operation for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh, without doing any thing to the tumor in the ham. The safety and efficacy of this mode have been confirmed by many subsequent trials; and it must be allowed to stand very high among the modern improvements in surgery.

If we consider Mr. Hunter at this period of his life, it will afford us a strong picture of the turn of his mind, of his desire to acquire knowledge, and his unremitting assiduity in prosecuting whatever was the object of his attention.

He was engaged in a very extensive private practice; he was surgeon to St. George's Hospital; he was giving a very long course of lectures in the winter; he was carrying on his enquiries in comparative anatomy; had a school of practical human anatomy in his house; and was always employed in some experiments respecting the animal economy.

He was always solicitous for some improvement in medical education; and, with the assistance of Dr. Fordyce, instituted a medical society, which he allowed to meet in his lecture-rooms, and of which he was chosen one of the patrons. This society, called the *Lyceum Medicum Londinense*, under his auspices and those of Dr. Fordyce, has acquired considerable reputation, both from the numbers and merits of its members.

In the year 1786, in consequence of the death of Mr. Middleton, Mr. Hunter was appointed deputy surgeon-general to the army. He now published his work upon the Venereal Disease; and his Observations on certain parts of the Animal Economy.

In the year 1787, his collection, which had been the great object of his life, both as a pursuit and an amusement, was brought into a state of arrangement; and he had then the satisfaction of shewing to the public a series of anatomical facts formed into a system, by which the economy of animal life was illustrated.

Upon the death of Mr. Adair, which happened in the year 1792, Mr. Hunter was appointed inspector-general of hospitals, and surgeon-general to the army. He was also elected a member of the Royal College of Surgeons in Ireland. In the year 1791, he was so much engaged in the duties of his office, as surgeon-general to the army, and his private practice, that he had little time to bestow upon scientific objects; but his leisure time, small as it was, he wholly devoted to them, as his various publications, at that period, evince.

Earl's Court to Mr. Hunter was a retirement from the fatigues of his profession; but in no respect a retreat from his labours; there, on the contrary, they were carried on with less interruption, and with an unwearied perseverance. From the year 1772, till his death, he made it his custom to sleep there during the autumn months, coming to town only during the hours of business in the forenoon, and returning to dinner.

It was there he carried on his experiments on digestion, on exfoliation, on the transplanting of teeth into the combs of cocks, and all his other investigations on the animal economy, as well in health as in disease. The common bee was not alone the subject of his observation, but the wasp, hornet, and the less known kinds of bees, were also objects of his attention. It was there he made the series of preparations of the external and internal changes of the silk-worm; also a series of the incubation of the egg, with a very valuable set of drawings of the whole series. The growth of vegetables was also a favourite subject of enquiry, and one on which he was always engaged in making experiments.

The collection of comparative anatomy which Mr. Hunter has left, and which may be considered as the great object of his life, must be allowed to be a proof of talents, assiduity, and labour, which cannot be contemplated without surprise and admiration. It remains an unequivocal test of his perseverance and abilities, and an honour to the country in whose schools he was educated, and by the patronage of which he was enabled on so extensive a scale to carry on his pursuits. In this collection (now possessed by the Royal College of Surgeons in London) we find an attempt to expose to view the gradations of Nature, from the most simple state in which life is found to exist, up to the most perfect and most complex of the animal creation—man himself.

By the powers of his art, this collector has been enabled so to expose, and preserve in spirits, or in a dried state, the different parts of animal bodies intended for similar uses, that the various links of the chain of perfection are readily followed and may be clearly understood.

This collection of anatomical facts is arranged according to

the subjects they are intended to illustrate, which are placed in the following order: *First*, Parts constructed for motion. *Secondly*, Parts essential to animals respecting their own internal economy. *Thirdly*, Parts superadded for purposes connected with external objects. *Fourthly*, Parts for the propagation of the species and maintenance or support of the young.

Mr. Hunter was a very healthy man for the first forty years of his life; and, if we except an inflammation of his lungs in the year 1759, occasioned most probably by his attention to anatomical pursuits, he had no complaint of any consequence during that period. In the spring of 1769, in his forty-first year, he had a regular fit of the gout, which returned the three following springs, but not the fourth; and in the spring of 1773, having met with something which very forcibly affected his mind, he was attacked at ten o'clock in the forenoon with a pain in the stomach, attended with all the symptoms of *angina pectoris*. In the life of him prefixed to his *Treatise on the Blood, Inflammation, and Gun-Shot Wounds*, the reader will find one of the most complete histories of that disease upon record. Suffice it, in this place, to say, that for twenty years he was subject to frequent and severe attacks of it, which however did not, till a short time before his death, either impair his judgment or render him incapable of performing operations in surgery. "In autumn 1790 (says Mr. Home), and in the spring and autumn 1791, he had more severe attacks than during the other periods of the year, but of not more than a few hours' duration: in the beginning of October 1792, one, at which I was present, was so violent that I thought he would have died. On October the 16th, 1793, when in his usual state of health, he went to St. George's Hospital, and meeting with some things which irritated his mind, and not being perfectly master of the circumstances, he withheld his sentiments; in which state of restraint he went into the next room, and turning round to Dr. Robertson, one of the physicians of the hospital, he gave a deep groan and dropt down dead; being then in his sixty-fifth year, the same age at which his brother, Dr. Hunter, had died."

It is a curious circumstance, that the first attack of these complaints was produced by an affection of the mind, and every future return of any consequence arose from the same cause; and although bodily exercise, or distention of the stomach, brought on slighter affections, it still required the mind to be affected to render them severe; and as his mind was irritated by tritles, these produced the most violent effects on the disease. His coachman being beyond his time, or a servant not attending to his directions, brought on the spasms, while a real misfortune produced no effect.

Mr. Hunter was of a short stature, uncommonly strong and active, very compactly made, and capable of great bodily exertion. His countenance was animated, open, and in the latter part of his life deeply impressed with thoughtfulness. When his print was shewn to Lavoisier, he said, "That man thinks for himself." In his youth he was cheerful in his disposition, and entered into youthful follies like others of the same age; but wine never agreed with his stomach; so that after some time he left it off altogether, and for the last twenty years drank nothing but water.

His temper was very warm and impatient, readily provoked, and, when irritated, not easily soothed. His disposition was candid, and free from reserve, even to a fault. He hated deceit; and as he was above every kind of artifice, he detested it in others, and too openly avowed his sentiments. His mind was uncommonly active; it was naturally formed for investi-

gation, and that turn displayed itself on the most trivial occasions, and always with mathematical exactness. What is curious, it fatigued him to be long in a mixed company which did not admit of connected conversation; more particularly during the last ten years of his life.

He required less relaxation than most other men; seldom sleeping more than four hours in the night, but almost always nearly an hour after dinner; this, probably, arose from the natural turn of his mind being so much adapted to his own occupations, that they were in reality his amusement, and therefore did not fatigue.

Though he spoke too freely, and often harshly, of other practitioners; in private practice he was liberal, scrupulously honest in saying what was really his opinion of the case, and ready upon all occasions to acknowledge his ignorance, whenever anything presented itself which he could not comprehend.

HUS, or HUSSO, a town of Turkey in Europe, in Moldavia, the see of a Greek bishop. Here Peter the Great made peace with the Turks. It is situate on the Pruth, 70 miles S.W. of Bender. Long. 28. 34. E. Lat. 46. 35. N.

HUSBANDRY (*Encycl.*). An improvement in the culture of turnips, by the use of the drill lately invented by Mr. Jackson, is spoken of under the article TURNIP in this SUPPLEMENT.

HUSSINGABAD, a town of Hindoostan, in the province of Malwa, but on the S. side of the Nerbudda, and the frontiers of Nagpore, the eastern division of the Mahratta empire. It is 140 miles N.W. of Nagpore. Long. 77. 54. E. Lat. 22. 42. N.

HUTANY, a town of the Deccan of Hindoostan, in the country of Visapour, 30 miles S.W. of Visapour. Long. 75. 6. E. Lat. 17. 5. N.

HUTTWIEL, a town of Switzerland, in the canton of Bern, 16 miles N.E. of Bern, and 22. N.W. of Lucern.

HYDRABAD, the capital of Golconda, in the Deccan of Hindoostan, seated on a river that falls into the Krishna, 352 miles N. by E. of Madras. Long. 78. 51. E. Lat. 17. 12. N.

HYDRABAD, a fort of Hindoostan Proper, in the province of Sindy, and the residence of a Mahometan prince, who is tributary to the king of Candahar. It is situate on the Indus, not far above the head of the Delta, and in the neighbourhood of Nusserpour. Long. 69. 30. E. Lat. 25. 29. N.

HYDROPHIANÆ, in natural history: a genus of semipellucid gems, composed of crystal and earth; the latter ingredient being in large proportion, and mixed imperfectly, as in the chalcedony; and giving a general cloudiness or mistiness to the stone; but of such an imperfect and irregular admixture, as not to be capable of a polish like the chalcedony; and appearing of a dusky and foul surface till thrown into water, in which they become lucid and in some degree transparent, either in part or totally; also changing their colour, which returns to them on their being taken out of the water. To this genus belongs the oculus belli of authors, or whitish grey hydropheanes variegated with yellow, and with a black central nucleus; and the oculus mundi, or lapis mutabilis, which is likewise a whitish grey kind without veins.

HYKES, a species of blankets, commonly used by the inhabitants of Barbary. They consist of a light woollen cloth, woven by women, who conduct every thread with their fingers, and without the aid of a shuttle. This manufacture appears to be a coarse kind of shawl, and is the more remarkable, as each of such hykes is from five to six yards in length, and breadth: it forms the whole apparel of the wretched natives, and serves them as a covering for their beds during the night.

I. J.

JAFFIERABAD, a town of the Decan of Hindoostan, in the country of Berar, 40 miles N.N.E. of Aurungabad, and 60. S. of Burhampour. Long. 76. 25. E. Lat. 20. 22. N.

JAGRSBURG, a town of Germany, in the principality of Hesse Darmstadt, 13 miles S.S.W. of Darmstadt.

JALALABAD, a town of Hindoostan Proper, in the country of Cabul, situate on the Kameh, 60 miles E.S.E. of Cabul.

JALLINDAR, a town of Hindoostan Proper, capital of a district of the same name, in the country of Lahore. It is 30 miles E. of Lahore. Long. 74. 10. E. Lat. 30. 50. N.

JALONITZA, a town of Turkey in Europe, in Walachia, on a river of the same name, 95 miles S.W. of Ismail.

JALOUR, a town of Hindoostan Proper, in the county of Agimere, 65 miles W.N.W. of Cheitore. Long. 73. 40. E. Lat. 25. 15. N.

JAMES'S POWDER (*Enceyl.*). To the receipts already given for making this valuable preparation, we have to add that of Mr. Chenevix, for preparing it by precipitation, by which it may be had at a cheaper rate. In his paper read at the Royal Society, this ingenious chemist gives the following account of his discovery :

"After the observations and experiments made by Dr. Pearson, to investigate the nature of Dr. James's Powder, and presented by him to this Society, very little remained to be effected or desired, towards a further knowledge of the subject. But those very experiments served to suggest, that the mode of preparation was far from being the best that the present improved state of chemical knowledge might afford ; and that, in all probability, a less defective composition might result from a process more conformable to some improvements, which of late have been advantageously applied to pharmaceutical chemistry.

"It may be laid down as a general principle, that, in delicate experiments, whether analytical or synthetical, fire (that potent and once believed to be universal agent) is too precarious in its means, and too uncertain in its application, to be employed with full and constant success. And, if it is still resorted to, the advantage of promptness, and a remnant of ancient custom, are the principal reasons. But, where other methods can be devised to effect the same combinations (and the humid way offers many), every person conversant in chemical knowledge will allow the benefit of adopting them. The recent improvement in the mode of preparing calomel, is a striking example of such salutary corrections being successfully introduced.

"A few observations upon the formula according to which Dr. James's Powder, or the *Pulvis Antimonialis*, is prepared, and upon some properties of antimony, will place this assertion in a more prominent point of view.

"In order to prepare this powder, we are told to take

equal weights of bone or hartshorn shavings and crude antimony, and calcine them together, at a high temperature : in other words, to take phosphate of lime, which already contains a great excess of lime, and add to it an oxide of antimony. In this process, it has been supposed, that the phosphoric acid of the bone or hartshorn will saturate, not only the lime with which it was originally combined, but, in addition to it, a new portion of metallic oxide, and a new portion of lime. For, what little sulphuric acid might, during the process, have been formed by the combustion of the sulphur of the crude antimony, is dissipated, at a much lower temperature than that to which the powder is exposed.

"Every oxide of antimony with which we are acquainted, is volatile at a high degree of heat ; it would therefore be hazardous to assert, that it is possible to preserve always the same proportion of antimony, whatever care may be employed in directing the operation ; and a dissimilarity in the chemical result must necessarily be attended with uncertainty in the medical application.

"To this property may be added another, no less conducive to error. That portion of oxide of antimony which is not volatilized, becomes, in a great measure, insoluble in all the acids. What the effect of the gastric juice may be, upon a substance which resists the action even of nitro-muriatic acid, is not my purpose to determine. It is sufficient for me to say, that, as the quantity of insoluble matter, in a given quantity of Dr. James's Powder, prepared at different times, may vary, the effect of any dose also may differ, according to the proportions of soluble and insoluble matter.

"I look upon it as a fortunate circumstance, that those experiments and observations which I mentioned in the beginning of this paper, existed as a standard to which I might refer my own attempts, and by which I might estimate their validity. Dr. Pearson has proved (as by my own experiments I have found), that in Dr. James's Powder about 28 per cent. resisted the action of every acid. In examining some of the *Pulvis Antimonialis* of the London Pharmacopœia, I found the average quantity of insoluble matter to be about 44 per cent. This proportion, however, was liable to considerable variation *.

"The powder here treated of is denominated, by Dr. Pearson, a triple salt, or real ternary combination of a double basis (lime and antimony), with phosphoric acid. What I have mentioned, with regard to the quantity of acid contained in bone or hartshorn, as being too small to saturate a new portion of these bases, may throw some doubts upon the possibility of any such combination in the present case. But I have made some more direct experiments, which tend to prove, that no such combination does exist.

"I took some white oxide of antimony (formerly called Algoroth Powder), precipitated by water from muriate of antimony, and heated it for a long time with phosphoric acid,

* I find, from the information of several medical gentlemen, that the *Pulvis Antimonialis* is generally considered as stronger than Dr. James's Powder. This seems rather extraordinary, when we consider that the quantity of insoluble matter is greater in the former than in the latter ; and would almost lead us to suspect it to be the active part of the medicine."

I decanted the liquor, and washed the powder that remained. No antimony could be found in the liquor; nor could any traces of phosphoric acid be detected in the residuary oxide of antimony. I then took a solution of muriate of antimony, and divided it into two equal parts: into one, I poured distilled water; and, into the other, a solution of phosphate of soda. In each liquor, a copious precipitate was formed; which precipitates, after being well washed, were dried. The weight of both was the same; whereas it is evident that, had any phosphoric acid been combined with the oxide, there would have been an augmentation of weight in that which was precipitated by the solution of phosphate of soda. This precipitate likewise, upon examination, gave no traces of phosphoric acid. From these experiments it appears, that there exists no combination, which can be denominated a phosphate of antimony.

"To attempt an explanation of the real nature of the powder here spoken of, I had recourse to some experiments of Mons. Berthollet. By detonating sulphuret of antimony and nitrate of potash in a crucible, he obtained a mass, which he reduced to powder, and washed. The liquor gave, upon evaporation, a crystallized salt, which M. Berthollet terms an *antimoniate of potash*. I never could succeed in any attempt to form a similar combination between the above white oxide of antimony and potash, owing, I believe, to the small quantity of oxygen contained therein, compared with that which is combined with the oxide obtained by detonation. I cannot therefore say, that the powder in question is, in any degree, what M. Berthollet would call an *antimoniate of lime*.

"But be the state, whether of mixture or of combination, what it may, my purpose is to endeavour to produce a substance, which, from its more certain mode of preparation, may be more equal and constant in its effects.

"Dissolve, together or separately, in the least possible portion of muriatic acid, equal parts of the fore-mentioned white oxide of antimony and of phosphate of lime*. Pour this solution gradually into distilled water, previously alkalinized by a sufficient quantity of ammonia. A white and abundant precipitate will take place, which, well washed and dried, is the substitute I propose for Dr. James's Powder.

"The theory of this precipitation is so clear and simple, that it does not require any comment. It may be useful, however, to those who wish to make this preparation, to remark, that it is absolutely necessary that the solution of phosphate of lime and of oxide of antimony, in muriatic acid, should, after being well mixed, be poured into the *alkaline liquor*, in order to obtain a precipitate homogeneous throughout the operation. For, should the alkaline liquor be poured into the *acid solution*, the water of the former would act upon the entire mass of oxide of antimony, while the alkali would precipitate the phosphate of lime only as it saturated the acid which held that salt in solution: thus, the precipitate would contain more antimony in the beginning; and, towards the end, the phosphate of lime would be predominant. For the same reason too, a pure alkali is pre-

ferable to its carbonate; for the carbonic acid disengaged, would retain in solution a portion of phosphate of lime.

"Whether this composition be a chemical combination or a mixture, I will not take upon me to determine; but, for the reasons above mentioned, in speaking of Dr. James's Powder, I believe it to be merely a very intimate mixture. At all events, it must be more homogeneous than any that can be prepared in the dry way. It is entirely soluble in every acid that can dissolve either phosphate of lime or oxide of antimony separately; and to have it constantly and uniformly the same, no further address in preparing it is required, than to avoid the errors I have mentioned.

"As, after some medical trials of the powder, it was suggested to me, that it might be more advantageous to render it somewhat stronger, I prepared another portion, by taking two parts of oxide of antimony and but one of phosphate of lime, and precipitating as above described. The medicinal power was then considerably increased.

"Dr. James's Powder is a medicine which has been so long in use, and is so deservedly ranked among the most valuable we possess, that every attempt to render the process for preparing it more simple and more certain, must be allowed to be of some importance. But, whatever reason there was to think, by arguing upon its chemical properties, that I had really succeeded in improving its medicinal virtues, it still remained to be proved, by actual experiment, that the hoped-for success was not merely conjectural. To ascertain this, I gave some of my powder to Dr. Crichton, Dr. Babington, and Mr. Abernethy; gentlemen whose extensive practice and acknowledged skill sufficiently enabled them to judge of its medical properties. They all concur in opinion, that, in its general effects, it agrees with Dr. James's Powder and the *Pulvis Antimonialis*; but, that it is more mild, and consequently may be given in larger quantities, seldom producing nausea or vomiting, in doses of less than eight or ten grains."

JAMSTO, a town of Sweden, in the province of Blekingen, 32 miles W. of Carlscrona.

JANVILLE, a town of France, in the department of Eure and Loire, 20 miles S.E. of Chartres. Long. 1. 47. E. Lat. 48. 12. N.

JAO-TCHOU-FOU, a city of China, in the province of Kiang-si, seated on the river Po, which, at a small distance, enters the lake Po-yang. It commands seven cities of the third class.

JAPARA, a sea-port on the N. coast of the island of Java, with a good harbour. It was the capital of a considerable kingdom, till the Dutch made themselves masters of it; and now they have a colony here, and a considerable trade. It is 253 miles E. by S. of Batavia. Long. 110. 45. E. Lat. 6. 20. S.

JARISBERG, a town of Norway, capital of a district abounding in mines, in the diocese of Aggerhuys, five miles N. of Tomfburg. Long. 10. 10. E. Lat. 58. 55. N.

JAULNAIS, a town of France, in the department of Vienne, six miles N. of Poitiers. Long. 0. 23. E. Lat. 46. 41. N.

* In order to procure the phosphate of lime, I dissolved in muriatic acid a quantity of calcined bone, and precipitated by ammonia in its state of greatest causticity. By this means, the excess of muriatic acid, which held in solution the phosphate of lime, is saturated, and the phosphate is precipitated; but no muriate of lime is decomposed, if the ammonia is quite free from carbonic acid. This is the most direct method of obtaining phosphate of lime pure. This salt is not decomposed, as some have asserted, by muriatic acid, but merely dissolved by it. I have been induced to state fully these particulars, because, from the beneficial effects of this salt in the treatment of rachitis, as proposed by M. Bonhomme (*Annales de Chimie*, vol. xviii. p. 113), it may become of general use. The oxide of antimony I obtained by precipitating, by water, the common butter of antimony of the shops.

ICE-BOAT. See *Ice-Boat, Supp.*

ICHTERHAUSEN, a town of Upper Saxony, in the principality of Gotha, 12 miles E.S.E. of Gotha. Long. 11. 1. E. Lat. 51. 48. N.

ICKWORTH, a town in Suffolk, with a market on Friday. Here are the ruins of an ancient priory, and several Roman coins have been dug up. It is 23 miles N.W. of Ipswich, and 74 N.N.E. of London. Long. 1. 0. E. Lat. 52. 22. N.

IDA, MOUNT. See *CANDIA*.

IDA, a mountain of Turkey in Asia, in Natolia Proper, famous, in ancient fable, for the judgment of Paris, and for being the resort of the gods during the Trojan war.

IDANHA-LA-NOVA, a town of Portugal, in the province of Beira, 3 miles S. W. of Old Idanha. Long. 6. 16. W. Lat. 39. 37. N.

IDANHA-LA-VELLA, a town of Portugal, in the province of Beira. The French took it by assault in 1704. It is seated on the river Ponsul, 25 miles N.E. of Castel Branco, and 20 N.W. of Alcantara. Long. 6. 14. W. Lat. 39. 39. N.

IDRIA, a town of Italy, in Friuli, and in the county of Goritz, with a castle. It belongs to the house of Austria, and there are rich quicksilver mines in the town itself. It is 17 miles N.E. of Goritz, and 25 N. of Trieste. Long. 13. 52. E. Lat. 46. 20. N.

IDSTEIN, a town of Germany, in Wetervaria, which is the residence of a branch of the house of Nassau, to whom it belongs. It is 12 miles N.E. of Mentz. Long. 8. 23. E. Lat. 50. 2. N.

JEAN, St. a town of France, in the department of Moselle and late province of Lorraine. It is seated on the river Sare, 12 miles W. of Deux-Ponts, and 8 N.W. of Sarguemine. Long. 7. 12. E. Lat. 49. 16. N.

JEAN-D'ANGELY, a town of France, in the department of Lower Charente and late province of Saintonge, with a late Benedictine abbey. It was taken from the Huguenots, in 1621, by Lewis XIII. who demolished the fortifications. It is famous for its brandy, and is seated on the river Boutonne, on which are two powder-mills; 15 miles N.E. of Saintes, and 32 S.E. of Rochelle. Long. 0. 20. W. Lat. 45. 50. N.

JEAN-DE-LONE, St. a town of France, in the department of Côte d'Or, and late province of Burgundy, seated on the river Saône, 15 miles S.E. of Dijon, and 155 S.E. of Paris. Long. 5. 19. E. Lat. 47. 8. N.

JEAN-DE-LUZ, St. a town of France, in the department of the Lower Pyrenées, and late province of Basques, the last next Spain, with a harbour. This little town owes its opulence to the cod and whale fishery. It is seated on a small river, near the sea, 10 miles N.E. of Fontarabia, 12 miles S.W. of Bayonne, and 315 S. by W. of Paris. Long. 1. 40. E. Lat. 43. 23. N.

JEAN-DE-MAURIENNE, a town of Savoy, capital of the county of Maurienne, in a valley of the same name, with a bishop's see. It is seated on the river Arc, 15 miles S. by W. of Montier, and 25 N.E. of Grenoble. Long. 6. 20. E. Lat. 45. 17. N.

JEAN-PIED-DE-PORT, St. a considerable town of France, in the department of the Lower Pyrenées, and late province of Lower Navarre. It is seated on the river Nive, and defended by a good citadel, upon an eminence, at the entrance of those passages, or defiles, in the Pyrenées, which, in this country, are called *Ports*. It is 20 miles S.E. of Bayonne, and 30 N.E. of Pampeluna. Long. 1. 33. E. Lat. 43. 12. N.

JED, a river of Roxburghshire, in Scotland, which joins the Teviot, a little below Jedburgh, at a place where the

Marquis of Lothian has an elegant seat, called Mount Teviot; and near this, on the W. side of the river, are the beautiful ruins of an abbey, founded by King David; a part of which ancient pile still serves for a parish church. On the banks of this river, are also several large caverns, which were the strong-holds, or hiding places, of ancient border warriors.

JEGUN, a town of France, in the department of Gers, eight miles N.N.W. of Auch, and 13 S. of Condom. Long. 0. 21. E. Lat. 43. 45. N.

JENA, a strong town of Upper Saxony, in Thuringia, with a university. It is seated on the Sala, 10 miles S.E. of Weimar, and 25 S.E. of Erfurt. Long. 12. 4. E. Lat. 51. 2. N.

JENITZ, a town of Upper Saxony, in the principality of Anhalt Dessau, situate on the Muldau, two miles N.E. of Dessau.

JENITZA, a town of Turkey in Europe, in Macedonia, situate on a lake which communicates with the gulf of Salonichi, by a canal 12 miles long. It is 24 miles W.N.W. of Salonichi.

JENO, a town of Upper Hungary, 20 miles S. of Great Waradin, and 48 N.E. of Segedin. Long. 21. 5. E. Lat. 46. 40. N.

JEREMIE, a town, jurisdiction, and cape, on the southern peninsula of the island of St. Domingo. The town is situate on an eminence, in a fertile soil, particularly excellent for the culture of coffee, five miles W. of St. Domingo. Long. 70. 14. W. Lat. 18. 18. N.

JERICHO, an ancient and famous town of Palestine, built by the Jebusites. It is now called Herubi by the Arabs, and contains only a few wretched huts, where some beggarly Arabs reside. It is five miles W. of the river Jordan, and 20 E. by N. of Jerusalem. Long. 35. 50. E. Lat. 31. 58. N.

JERICHO, a town of Lower Saxony, which gives name to a circle or division of the duchy of Magdeburg. It is situate on the Elbe, 32 miles N.N.E. of Magdeburg.

JERMAH, a town of the kingdom of Fezzan. It is distinguished by the numerous herds of sheep and goats, that are seen around it; by the various and abundant produce of the adjacent fields; and by the numerous and majestic ruins, that exhibit to the inhabitants of its clay-built cottages, inscriptions of which they know not the meaning, and vestiges of greatness to which they are perfectly indifferent. Jermah is 60 miles S.E. of Mourzook. Long. 17. 17. E. Lat. 27. 5. N.

ILAK, or JALAK, a town of Nubia, on the Nile, supposed to fume to be the ancient Meroe. Long. 34. 30. E. Lat. 18. 48. N.

ILLE, a town of France, in the department of the Eastern Pyrenées, 10 miles S.E. of Perpignan. Long. 3. 5. E. Lat. 42. 35. N.

ILLER, a river of Germany, which rises in Tirol, runs N. through Suabia, passing by Kempten, Memmingen, and Kirchberg, and falls into the Danube, at Ulm.

ILLESCAS, a town of Spain, in New Castile, 15 miles S.S.W. of Madrid, and 15 N.N.E. of Toledo.

ILLOCK, a strong town of Slavonia, seated on the Danube, 15 miles from Peterwaradin, and 55 N.W. of Belgrade. Long. 20. 6. E. Lat. 45. 36. N.

ILM, or STADT-ILM, a town of Upper Saxony, in the county of Schwartzburg-Rudolstadt, 14 miles S. of Erfurt.

ILMEN, a lake of Russia, in the government of Novogorod, about forty-eight miles long, and twelve to eighteen wide; Novogorod is situated near it. Long. 34. 0. E. Lat. 58. 0. N.

ILMINSTER, a town in Somersetshire, with a market on Saturday; seated in a dirty bottom, among hills, 26 miles S.W. of Wells, and 137 W. by S. of London. Long. 2. 54. W. Lat. 50. 55. N.

ILSLEY, or **EAST ILSLEY**, a town of England, in the county of Berks, with a weekly market on Wednesday: 14 miles N.W. of Reading, and 53 W. of London. Long. 1. 12. W. Lat. 51. 32. N.

ILST, or **YLSST**, a town in the state of Friesland, defended by a ditch filled with the waters of the river Weymer: 12 miles N.E. Staveren, and five S.E. Bolsward.

ILSTROP, a town of Sweden, in the province of West Gothland: 27 miles S.S.E. of Gotheborg. Long. 11. 51. E. Lat. 57. 23. N.

ILTEN, a town of Germany, in the circle of Lower Saxony, and principality of Lunenburg: sixteen miles S.S.W. of Zell.

ILTZHOFEN, a town of Germany, in the circle of Swabia, in the territory of Halle: eight miles N.E. of Halle.

IMBRO, an island in the Grecian Archipelago, mountainous and woody, with plenty of game: it is about 20 miles in circumference, and contains five villages, two of which are defended by castles. Long. 25. 44. E. Ferro. Lat. 40. 10. N.

IMENSTADT, a town of Suabia, 20 miles E. of Lindau. Long. 10. 20. E. Lat. 47. 35. N.

IMMENHAUSEN, a town of Germany, in the principality of Hesse Cassel, eight miles N.N.W. of Cassel, and 16 N.E. of Naumburg.

IMMENSTADT, a town of Suabia, in the county of Konigsberg, situate on a small river, which soon after falls into the Iller, 12 miles S. of Kempten, and 14 S.E. of Iny.

INDAPOUR, a sea-port on the S.W. coast of the island of Sumatra. Long. 100. 50. E. Lat. 1. 30. S.

INDEN HOTUN, a town of Chinese Tartary, the capital of the Manchevo Tartars, where they began to establish their empire over China. It is 420 miles E.N.E. of Pekin. Long. 124. 36. E. Lat. 41. 45. N.

INDIGO (*Encycl.*). The following is an extract of a Memoir on the Cultivation of the Indigo-plant, and the preparation of Indigo, read by Citizen Brulley, at a public meeting of the Lyceum of Arts, in Paris.

"Indigo," says he, "is known to be a precipitated fecula, dried and reduced into a solid mass, light, brittle, and of a very deep azure colour. This substance is of great utility in the arts. A great consumption is made of it in dyeing, painting, bleaching, and other processes of different manufactures.

"The vegetable which produces this colouring fecula is termed the indigo-plant, *indigo-fera*. It is of the genus of the polypetal plants, of the family of the leguminous, and has much resemblance with the *Galegas*.

"There are twenty-seven species of indigo-plants. To enumerate their differences and describe their botanical characters would be superfluous. It will be sufficient to direct our attention to the most interesting species, namely, that which yields the best indigo. It is termed *indigo-franc*, *indigo-fero anil*. It is indigenous in America; and is cultivated with success in the Southern parts of this country, and in the Antilles. In these islands is found a variety of the best species of indigo, which grows to twice the height of the indigo-franc. It is termed the wild indigo-plant or maron.

"It is to be remarked, that in the French colonies in the Antilles, where fine indigo is prepared, the seed of the indigo-franc is purposely mixed with that of the indigo-maron, in order to obtain a more considerable and better product. The purposes for which this mixture is made, as well as all the operations belonging to the cultivation of the indigo-plant,

are related in a detailed memoir that has been laid before the Lyceum of Arts. For the present we shall confine ourselves to giving an account of an essential improvement in the preparation of indigo.

"It will undoubtedly be heard with astonishment, that though indigo has been manufactured during the space of nearly a century, its preparation still consists in such imperfect approximations, that, even with the best manufacturer, generally ten, fifteen, and even to the number of twenty-five tubs fail, out of a hundred which he undertakes. Sometimes even, either owing to want of experience or the contrarieties of temperature, a much larger number of tubs fail, and ruin the proprietor, who reckons upon large profits: hence in part arises the high price of indigo.

"But should the proprietor of indigo-plants be secured, by means of a certain process, against the danger of losing the fruits of his expence and labour, he would then be able to sell his indigo at a cheaper rate. This would be a great advantage to the arts and manufactures, and consequently to the commerce of France.

"This great advantage France will at some future period be able to enjoy, and she will owe it to the labours and intelligence of one of the colonial proprietors of St. Domingo, who is at present in France, and one of the free associates of the Lyceum of Arts, I mean Citizen Nazon. Judicious observations and a long course of experience have convinced him that it is possible to ensure the success of all the tubs of indigo.

"In order to obtain this colouring substance, the indigo-plant is cut when it has arrived at its maturity. The whole is put to macerate in a basin of brick-work, which is termed the tub (*cure*). Its dimensions are generally twelve feet.

"To bring the maceration to its ultimate point, requires from fifteen to thirty and even thirty-six hours, more or less, according to the temperature of the atmosphere at the time when the operation is performed; it is also necessary to take into consideration the quality of the indigo-plant, the nature of the soil that has produced it, and that of the water in which it is immersed.

"The first indication from which it is judged that the maceration begins to approach its ultimate point, is the sinking of the scum, which elevates itself in the space of about half a foot, which has been left empty in the tub, including the plants. When this scum has become a kind of crust of a copper-blue colour, the moment is concluded to be near at hand, at which the plants will be sufficiently macerated. However this indication is insufficient and often even fallacious. There is another upon which greater reliance is placed: it consists in drawing off a small quantity of the water by means of a cock placed at the lower part of the tub. It is received into a silver cup, and it is observed whether the fecula tends to precipitate itself to the bottom of the cup: when this is the case, it is concluded that the plants have attained that degree of maceration which is requisite for obtaining the indigo from them.

"Such was the process most generally practised; but it too often gave rise to error. To avoid this we have a sure means, which consists in accurately observing the water contained in the cup: five or six minutes after it has been poured into it, it forms round the sides of the cup a ring or edge of fecula, which at first is of a green colour and afterwards becomes blue. As long as the maceration has not yet been carried to the proper pitch, this ring detaches itself, with difficulty from the sides of the cup. But at last it is seen to precipitate and concentrate itself at the bottom of the vessel, always towards the centre, under the water, which has become limpid, though with a yellowish tinge.

"When these appearances are observed, they infallibly indicate the success of this first operation. The water is then drawn off into a second basin or tub, placed beneath the first. This second tub is termed *batterie*, as its use is for beating the water still charged with the fecula. In order that it may separate quickly, it is agitated. This operation is performed either by the labour of the hands, or by means of a mill. It is of essential consequence not to agitate it for too great a length of time: excessive agitation mixes anew the fecula with the water, from which it does not separate any more, and the tub fails. Instead of indigo, we obtain nothing but muddy water.

"This latter inconvenience may easily be obviated by a little attention. When we have discovered that the fecula is sufficiently united, we draw off the water from the *batterie* into a third and smaller basin, which is termed the *diablotin*. We then find the bottom of the *batterie* covered with a very liquid blue paste; this is received into bags of coarse linen cloth, of the form of inverted cones, which suffer the watery part to run off. These bags are afterwards emptied of their contents upon tables in the drying rooms, where this blue paste is kneaded, and after it has acquired a denser consistence, it is spread out and cut into small squares, in order that it may dry the sooner. The manufacture of the indigo is now completed, and it is soon after sufficiently dry to be introduced into commerce.

"I omit the details contained in a longer memoir, of which I confine myself to giving an extract. What was of importance to be made known, is that there exists a certain process, by following which one may be secure against failure in the manufacture of indigo.

"Experience has shewn that this process has never failed of complete success; of this, more than 1500 tubs of indigo

manufactured in different parts of St. Domingo, have furnished the proofs."

INDUSTRY. "The following extract from an account of a Society, for the promotion of industry, in the county of Essex, by John Conyers, esq. appears in the Reports of the Society for bettering the Condition of the Poor, &c.

In November, 1794, a meeting was held at Epping in Essex, to take into consideration a proposal for the promotion of industry in that neighbourhood*. An association was formed of fourteen parishes, the parochial subscription being agreed to be one per cent. on their rates, and that of individuals not more than five shillings each: This, with a few benefactions, produced in 1795, the sum of 154l. which was purposed to be set apart as a fund† for giving annual presents of clothing to those children who should produce the best specimens of industry; and sums of money, not exceeding 10l. each, for any such young person on their going to apprenticeship, or service, or being married, according to the number of annual prizes such young persons should have obtained; and also rewards in money to poor persons who had brought up four or more children to the age of fourteen years without parish relief, and to overseers who should distinguish themselves in the execution of their office, and in the employment of the poor. The society at the same time took measures for having work-rooms and teachers provided in the different parishes, and spinning wheels and a supply of work for the poor at their own houses; and also for ensuring to them that they should be paid by their parishes the full price‡ of their work; which, though making a difference of only three pence or four pence in the pound, and being a very trifling expence to the parish, was, nevertheless, to the individual who received it, a very powerful reward and encouragement.

* The plan alluded to "was founded on one of the wisest and most humane laws, which this country has to boast of; and which was passed in the forty-third year of Queen Elizabeth's reign, for the maintenance and employment of the poor. The object of this act was; not merely to relieve the *indigent*, but to prevent *indigence* itself. It was calculated not only to guard against poverty and distress, but against vice and immorality also. It regarded the mental, as well as the corporeal welfare of those whom it professed to protect. He could not avoid observing the superiority of the act just mentioned, over some of the acts which have been since passed for the regulation of the poor; acts which permitted parishes to *farm their poor to governors of workhouses* (whose interest it was to make as great a profit of them as possible), and to *affix badges to the clothes of beggars*. These regulations had indeed made it painful to indigent persons of any sensibility to apply for relief, which the infirmities and calamities, incident to human nature, rendered necessary for them; but neither of these measures had reduced, or was likely to reduce, the number of the poor, or to correct the profligacy of their manners."

† The reader is referred for further particulars, to a printed account of the institution, published for the benefit of the Society, and sold by Cadell and Davies in the Strand.

‡ The poor, who might otherwise be inclined to spin yarn, labour under great discouragement, arising from the manner in which they are paid for their work when finished. The shop-keeper of whom they get their yarn, professes to pay them at the rate of a penny per hank; but, when the work is returned to him, he deducts three pence or four pence (or in cases when the trade has been slack, five pence) from every pound of wool spun. This is considered as the woolstapler's profit. Thus an indifferent spinner, who makes but twelve or perhaps ten hanks of a pound of yarn, gets but eight pence or six pence for her work. But this is not the only discouragement. The shop-keeper makes a favour of supplying her with yarn, and will not supply her with any, unless she will consent, not only to take out in shop goods the amount of what she earns by spinning, but will engage to purchase of him alone such necessaries for her family as his shop will furnish. By these means she is precluded from laying out her money at any other shop, where she thinks she could get articles of a better quality, or at a cheaper rate; and is obliged to submit to any imposition, which a grasping shop-keeper may lay upon her.—The committee of industry in Essex, considering their fund as insufficient for the purpose of relieving the poor from this oppression, by paying them the full price of their work, has recommended the plan to parishes. In that of Chipping Ongar, by the attention of the Rev. Mr. Herringham and some of the principal inhabitants of the parish, this plan has been carried into execution, and has produced a very good effect. The parish procures a flock of wool from a worsted maker: this is deposited at the workhouse; and the poor, upon application to the person who has the management of this business, obtain from him a ticket; which being taken to the mistress of the workhouse, she delivers the wool, and files the ticket. The work, when finished, is carried to the person who gave the ticket, and he immediately makes a payment in money, deducting (for the present) four pence for every pound of work. This is done merely to prevent carelessness in spinning, or frauds in reeling; and the groats so deducted are withheld, till the whole flock of wool is returned to the manufacturer, where every spinner's

At a meeting of the society on the 31st of December, 1795, there were 52 children candidates for prizes, as spinners and knitters; and 21 parents, who had brought up four or more children in lawful wedlock without parish relief. The parents received donations, not exceeding two guineas each, varied according to the number of their children, and other circumstances: and 31 of the children received presents, in clothing, not exceeding twenty shillings each, according to their different merits. They also received, with the premiums, certificates of good behaviour, which they consider as marks of distinction, and of which they will feel the benefit through life.—In the ensuing year, an equal number of parents received donations, on account of the families they had brought up; and clothing, to the amount of 30*l.* 15*s.* was given to 37 children, who had then produced the specimens of industry, in spinning, knitting, and plain needle-work.—In the present year (Jan. 1798), donations of clothing have been made to 61 industrious children to the amount of 51*l.* 15*s.*; and to parents, the sum of 23*l.* 12*s.* 6*d.* on account of the families which they have brought up.

This establishment, formed on the same plan as that of the Rev. Mr. Bowyer in Lincolnshire, and rendered successful by the great attention given to it by the trustees of the different districts, requires very little comment. It is obvious that its operation, by the most pleasing and acceptable means, those of *encouragement and attention*, must be to increase the industry and good habits of the poor in the neighbourhood, and greatly to improve the rising generation. The donations may appear small to those who have not sufficiently attended to the circumstances of the labouring poor, to learn that the very trifling rewards, given with *kindness*, in a *disinterested and honourable* way, and unincumbered with any *humiliating condition*, will do wonders in exciting the industry and economy of the cottager; and in attaching him, by every tie of gratitude and affection, to those who feel sufficiently the obligation of *their own duty*, to become the friends and benefactors of the poor.—We cannot omit taking this opportunity to observe, that every measure of this kind should be so framed and conducted, that the motives may not merely escape the *guilt of being interested*, but be exempt from the *discredit of being suspected*.

In April, 1796, a meeting of the inhabitants of Lewisham was called, for the purpose of setting up a school of industry, for the children of that parish. The subscribers came to a resolution to prepare accommodations for the reception of 60 children, and the house was opened on the 30th of May, 1796.

The children are admitted on the recommendation of subscribers, and by order of the committee. In summer the school is open from six o'clock in the morning to six at night, and in winter during the hours of daylight; but the children have usually finished their task by two o'clock; they then go away, unless, which is the case with some of them, they prefer to work additional hours on their own account. They

receive two meals a-day, a breakfast and a dinner; one hour being allowed at dinner, and half an hour at breakfast. They are employed in spinning, winding, and knitting; and one boy in weaving. The present weaver is an active boy, not ten years of age; his predecessor had been employed but a very little time, before he had an offer of a permanent engagement at a cotton mill. In rotation they all receive lessons in reading. The children's weekly maintenance is estimated at *1*s.* 6*d.** per head; and where they earn more in any week (as some do 6*d.* a-week, and some *1*s.**) they are paid, and carry home the overplus. One little boy (who came from the work-house with but a bad character, but who now possesses a very good one) earns not less than an extra shilling a-week; he has during the last month, put into the master's hands, in trust for him, the sum of 5*s.* In the case of the parish children, who are entirely maintained at the parish expence, there is, as yet, no certain allowance; but they are rewarded according to their industry and good behaviour. It is however in contemplation to make them a certain allowance; probably a sixth of their weekly earnings.

Spinning wheels are lent, and materials are furnished at home, for any of the adult inhabitants of the parish, who wish employment; and they are paid for their work upon delivery. A suit of clothes, made of the cloth and camblet of their own manufacture, is yearly given to each of the children, who attend the school, as a reward for their good behaviour, and to enable them to appear decently and regularly at church on Sundays.

In the infancy of a manufacture, there is necessarily a loss from the waste of raw materials. In the present instance it must be admitted, that very little profit accrued from the labour of the children, during the first six months: but for the next half-year, the profit was gradually increasing; and it advanced so much, that at the end of the year, on the 30th of May, 1797, the net profit of the manufactory had amounted to 55*l.*—That profit may be fairly stated at *100*l.** a-year in future. The school of industry now supplies the parish work-house with most of their articles of clothing: besides which, a stock of knitted stockings, and of camblets and worsted, is kept in the warehouse, to be sold by wholesale and retail. The demand for them has been gradually increasing; and the inhabitants have found their advantage in the purchase of them.

The weekly expence of the family, upon an average, is 3*d.* a-head per day; including the * 20 parish children, and the master and mistress and their two children, who have their three meals a-day, and lodge in the house. For each of the parish children the establishment is allowed the sum of 3*s.* a-week; which is near 50*l.* a-year less than the expence of merely feeding them in the work-house, during the preceding year.

The following is a pretty correct estimate of the expences and receipts of the establishment.

work is ticked with her name.—Upon receiving the approbation of the manufacturer as to the work, the spinners are paid their groats; and far from complaining of their being withheld in the first instance, they express a satisfaction at having “a lump of money” as they call it, to lay out in clothing. The account is kept as follows:

Names.	Work issued.	When issued.	When returned.	No. of barks.	Money paid.	Groats due.
M. Westwood.	3 lb.	Mar. 15, 1798.	Mar. 19.	3 ⁰	2 <i>s.</i> 0 <i>d.</i>	3
Ann Smith.	4 lb.	Mar. 16, 1798.	Mar. 21.	4 ⁸	2 <i>s.</i> 8 <i>d.</i>	4

* This number occasionally varies; there have been 23 in the school at a time: but the number will probably be much less.

PAYMENTS.

Maintenance of the family, clothing, &c.	250	0
Wages of master and mistress; 10s. per week. <i>He is extremely well acquainted with every process in the woollen manufacture</i>	26	0
School mistress; who teaches the children to read	3	0
Rent of the house, and the wooden building behind, <i>It was a blacksmith's shop, but is now the school and work-room</i>	13	10
Insurance	1	0
Mr. Hall, the manager, who does not live in the house, but attends occasionally. <i>He purchases the provisions and materials for the work, and provides a sale for the articles of manufacture</i>	30	0
Incidents, gratuity to the secretary, &c.	26	10
	350	0

RECEIPTS.

Parish rents appropriated to the institution	60	0
Allowance for 20 parish children, at 3s. a-week each	156	0
Profits of manufactory per annum; supposed	100	0
	316	0
Deficiency in the infancy of the establishment, to be made good by subscription	34	0
	£. 350	0

There are 48 persons, including the master and mistress and their two children, who breakfast and dine regularly in the house. The table of diet, and quantities allowed for them, which are quite as much as they wish, are as follows: Monday. Breakfast. Rice milk; made of 4 lb. of rice, 1 lb. of flour, 1 lb. of sugar, and 4 quarts of milk. Dinner. 20 lb. of beef, and a peck of potatoes, with 17 lb. of bread.

Tuesday. Breakfast. Broth and 13 lb. of bread. Dinner. Boiled rice; consisting of 15 lb. of rice, 1½ lb. of sugar, and 3 quarts of milk.

Wednesday. Same as Monday.

Thursday. Same as Tuesday.

Friday. Breakfast. Gruel, made of 2 quarts of oatmeal, with the allowance of 1 lb. of butter, 11 lb. of bread, and ½ lb. of salt.

Dinner. Beef-stew; consisting of 22 lb. of flints of beef, and a peck of potatoes, with 17 lb. of bread.

Saturday. Same as Tuesday and Thursday.

The workhouse children and the master's family (in all 24) have, for their Sunday breakfast, gruel, made of one quart of oatmeal, with the allowance of half a pound of butter 8 lb. 10 oz. of bread, and 4 oz. of salt; for dinner, 12 lb. of beef, half a peck of potatoes, 5 lb. 5 oz. of bread, 8 oz. of salt, and 3 quarts of beer; for supper on Sunday, 6 lb. 8 oz. of bread, ¾ lb. of cheese, and 2 quarts of beer, and the same supper on the other days of the week, with a little additional allowance of bread, of which they seem to require more on week-days than on Sunday. The price of the beef is 3s. a stone, or 4½d. per pound; of the 2 flints of beef (weight per average, including bone, 22 lb.) 2s. 6d.; of potatoes 20d. a bushel; of their bread, which is good seconds, 7½d. the quarter loaf, or rather more than 1½d. a pound.

By the preceding bill of fare it will appear, that the cheap article of rice now forms a very considerable proportion of the children's diet. The use of it has been gradually increased, partly in consequence of their having acquired a greater fondness for it than for other food, and partly from the observation of its nutritive and wholesome qualities. Its average increase, on boiling in mere water, has been found to be fourfold: with

the addition of milk, it is much more.—The good health which the children have uniformly enjoyed has been remarkable: several of them who were weak and sickly at their admission, have since become healthy and vigorous; to which their new habits of cleanliness and regularity, and the exercise of spinning by hand-wheels in an airy apartment, as well as their diet, which is nutritious and plentiful, may probably have conducted. The improvement in their morals and behaviour has been equally satisfactory to the wives of the promoters of the institution. It is found that, in proportion as the children become skilful and useful, their parents and friends, learning their value, become desirous of withdrawing them, because they can employ them to more advantage. This has already been the case of many, and generally has happened in the course of six months after they have been received into the school; as the habits of order and industry, which the children acquire there, render them so desirable as apprentices, that, though there has been a difficulty heretofore in finding situations in private families for any parish children, because *they came out of a workhouse*, yet they are now sought for, and the parish is relieved from the expence of their maintenance at a much earlier age, than if they had been kept in the workhouse.

One other very great advantage resulting from this establishment, and from its necessary connection with the poor of the parish, is, that the gentlemen who have interested themselves in its success, have thereby been induced to take a very active part in the management of the poor; and one of them, Robert Saunders, esq. is now serving the office of overseer for his second year. It will be obvious that a greater benefit to the poor, and a considerable saving to the parish, must be the consequences of such an institution. The poor are more happy, and better taken care of, than they were before; and the saving, from the new system, will hardly be less than 500s. a-year.

By the preceding account it will appear, how much may, at a very small expence, be effected by a judicious and spirited adoption of one of the measures directed by the statute 43d Elizabeth. It is needless to observe upon the effects which this establishment has necessarily produced on the morals, the cleanliness, and the health of the children; who, being now habituated to industry, instructed in reading, and accustomed to a regular attendance on divine service, are bred up in the knowledge and practice of obedience and reverence to their Creator, and of that utility, which he has enjoined as a duty to their fellow-creatures.

Besides the advantage of separating the parish children from the contagion of those dissolute and profligate characters, which are to be found in all workhouses, the maintaining of them at a less expence, and the educating of them in the habits of industry and virtue (circumstances which apply to the parish children removed from the workhouse to the school of industry), it should be observed, that a very great relief is also given to the other poor of the parish, by easing the parents of the burthen of maintaining so many of their children, and by giving the mothers profitable employment at home; a relief that, by improving the circumstances of the cottager, has a just and honourable tendency to reduce the poor's rates.—Establishments, like that at Lewistham, have also the merit of correcting the little pilfering habits of the infant poor, the source of so many vices and crimes in society; and of preserving them from idleness and bad example, and training them in virtuous and industrious habits, so as to make them blessings to their parents, and useful and valuable members of society."

For the benefit of the adult poor, a society was instituted at Wendover, by the Rev. Joseph Smith, who, in the ac-

count of the steps taken to establish it, says, "I confined my endeavours at the commencement, to inducing, in all my poorer neighbours, a habit of saving some part of their earnings, during that period of the year when they could best spare it, against a time when they would most want it. To the poor, therefore, both male and female, and of all ages, I proposed that part of the plan only; as the means of laying up, from the excess of the most productive part of the year, that which might procure them comfort and relief at the season the least productive, and the most expensive; and, in order to make it generally known, I employed the schoolboys at the writing school in the parish, to copy out proposals, for a weekly contribution of money during the summer months, to be repaid them with a considerable increase, the addition of one-third at least, at the end of the year. Certain gentlemen were named to "receive at their houses weekly sums, of 2d, 3d, 6d, or more, and deposit the same in a box provided for that purpose, and keep an exact account of the same in a book. It is proposed that Sunday morning be the time of making the payments; because, among the other duties of that day, the labourer can then best spare time to look forward for the future comfort of his family; and because they who have attended their duty at church, after having paid in their weekly six-pence to accumulate for their families, will feel the less inclination to spend another six-pence idly at the ale-house. At Christmas the distribution will be made; that is to say, for every three shillings paid in, not less than four shillings shall be returned; and so in proportion. Further attention and consideration will be paid to those who have made their payments regularly, and who have been regular in their duties at church. Any person may receive back his or her own money at any time before Christmas; but without any addition thereto. It is not intended that this act of prudence in the poor should preclude them from parish relief, in case of sickness, or in case of want of work, during severe weather; but it is meant to enable them to purchase a warm garment, half a load of wood, or any other domestic comfort they may want at the most inclement season. The donations and friendly communications of any of the parishioners to this undertaking, are thankfully received."

Copies of this paper were placed on the church doors, and distributed in the parish. The boys also, who had received a trifling gratuity for making the copies, contributed very much to make the terms known to their parents and connections. "We gave notice of receiving contributions," says Mr. Smith, "on the first Sunday in May.—The labourers have embraced the offer held out to them, in a manner extremely gratifying; the society already consisting of near sixty subscribing labourers, who bring their subscriptions very regularly after morning service; none less than six pence, very many of them a shilling."

The above may be deserving of attention in those country parishes, which, like Wendover, are not capable of receiving the entire benefit of the plan adopted in the bishopric of Durham. It is certainly of great importance, to induce habits of frugality and foresight, among the poor. These good qualities are rarely unaccompanied by the other virtues; and when they are wanting, there can be little hope of strict moral or religious character among men, who are to subsist on the produce of their daily labour.

There is a peculiar advantage in the Wendover society, that neither time, nor money, is expended in ale-house meetings. There are no incidental charges to exhaust the common purse. There is a sure and certain benefit to the members; and there exists no expense to diminish the amount of it. Friendly societies, though very deserving of encouragement, are not always equal and certain in their effects.

If not conducted properly, they may degenerate into drunken meetings; they may be disgraced by fraud, be directed by a party, and become the instruments of sedition. From these inconveniences the society at Wendover is exempt. Their one entertainment will be only an annual addition given to their family dinner at home, on Christmas-day.

A great advantage of this and of some other similar establishments (besides that important one of uniting persons together for a common and useful purpose) is, that they contribute to make the rich and the poor more known to, and more connected with, each other; and to give those who are desirous of making a proper use of their property, an opportunity of appreciating correctly the character and situation of most of the cottagers in their neighbourhood.

The establishment of this society will, it is to be hoped, prove of much greater advantage to the members, than the mere amount of the addition to their own savings; and will be the cause of their beginning the new year not only happily, but wisely. We understand they derive permanent good effects already from their frugality and prudence; Mr. Smith having established the society on a more durable footing, and with additional improvement and benefit to the members.

INFECTION (*Encycl.*). Under the article **CONTAGION**, we have spoken fully on this subject; and have under **FEVER** in this **SUPPLEMENT**, inserted some useful cautions for the security of those who are necessarily exposed to danger from this cause. The following paper on the means of purifying infectious air, &c. is extracted from a work of Citizen Guyton de Morveau, by Citizen Deyeux, and published in the *Annales de Chimie*.

"Amongst the important discoveries, which we owe to chemistry (says the latter writer), those chiefly deserve our attention, which, at the same time that they present us with facts valuable in a scientific point of view, afford also results from which great advantages may accrue to society in general. It is then, chiefly, that the utility of chemistry ceases to be a problem, and that we are compelled to acknowledge the just title, which this science has to be ranked amongst those, the study of which ought most assiduously to be cultivated.

"The work, of which I am about to give an extract, we owe to a distinguished man of learning, a profound chemist, who, having meditated for a long time upon various important phenomena, that had presented themselves to him under a multitude of circumstances, conceived that he might make use of the knowledge which he had acquired, in order to combat one of those scourges which desolate the human race, and against which all the art of medicine has hitherto proved insufficient.

"Having once conceived this idea, he had a difficult task to accomplish. Citizen Guyton, however, has surmounted all the obstacles that stood in his way, and, by his courage, his patience, and perseverance, has obtained such satisfactory results, that he thought he ought no longer to withhold from the public the fruits of his labours.

"His work is divided into six parts. In the first, the author gives an historical sketch of the experiments which he made in the year 1773, with the muriatic acid employed in fumigations.

"Already, at this period, he says, attempts had been made to disinfect the air tainted by putrid miasmata; but, as all the substances that had been employed for this purpose had not produced the effects that were expected from them, I imagined, after long reflection upon the subject, that I ought to turn my attention to the muriatic acid; as the great expansibility of its vapours led me to suspect, that they might be proper for seizing upon the ammoniac, which I then supposed to accompany all the odorous putrid miasmata, and for

compelling it to quit them, and leave them to subside by their own gravity.

"It was necessary to ascertain the powers of the remedy, which theory seemed to point out, by the test of experiment: Citizen Guyton, therefore, availed himself of a circumstance, which he thought it the more necessary for him to make use of, as it afforded him an opportunity of making an experiment upon a large scale, and such as he stood in need of, in order to obtain results concerning the nature of which no doubt could remain.

"In the course of the winter of 1773, the burying-vaults of the principal church at Dijon being found to be entirely full, it was ordered, that they should be cleared. Some precautions that had been taken, with a view to prevent the exhalation of the putrid vapours, which, it was presumed, must arise during this operation, having proved unsuccessful, the infection soon became so insupportable, that it was necessary to abandon the church. In the mean time, the putrid effluvia diffused themselves among the neighbouring houses, and then gave rise to a contagious fever.

"It was then that it was thought proper to consult Citizen Guyton, who, after having informed himself of all the precautions that had been used, proposed fumigations with muriatic acid.

"His advice was adopted; and the effects were so speedy and decided, that, four days after, the church was re-opened, and all the ecclesiastical offices were re-established in it, without danger, and even without apprehension.

"Similar fumigations were afterwards practised in the dungeons of the prisons of Dijon, in which a contagious fever had produced such terrible effects, that the greater part of the prisoners perished.

"Though the infection was of the most virulent nature, it was at last so completely destroyed, that a student of surgery requested leave to sleep in one of the dungeons that had been disinfected.

"Success so decided, naturally produced a great deal of confidence in the remedy. We find, therefore, that when the *Conseil de Sante & Vieq d'Azyr* were consulted upon the means of stopping the progress of a contagion that had appeared in the military hospitals, and in the stables where a great number of cattle were kept, they did not hesitate to prescribe fumigations with muriatic acid, as the most certain remedy to which they could have recourse.

"A circumstance, which certainly ought to excite surprise, is, that the persons, to whom the care of executing these fumigations was intrusted, neglected to give sufficient publicity to results so satisfactory as those which it is known they obtained.

"This neglect, as Citizen Guyton very justly remarks, is the more unpardonable, as it has tended to retard the adoption of a process, which, in many cases, would have proved invaluable, as, by means of it, many thousands of persons might have escaped the effects of contagions, to which they have fallen sacrifices, on account of the insufficiency of the means that were employed against them.

"The muriatic is not, it appears, the only acid which has been considered capable of depriving the air of its contagious quality. This we find from the account which the author gives, in the second part of his treatise, of experiments made in foreign countries with fumigations of different mineral acids.

"One of the oldest works relative to this subject, which fell into the hands of Citizen Guyton, is entitled *Rapport des Experiences faites en Angleterre, par Ordre de l'Admirauté, à bord du Vaisseau d'Hôpital, l'Union*.

"The Lords of the Admiralty having requested Dr. Smith

to direct means for putting a stop to the contagion that had appeared on board the *Union*, he advised Mr. Menzies, surgeon to the navy, to try fumigations with nitric acid. These fumigations were made with great care, and were attended with such success, that, from the day on which they were begun to be employed, the mortality ceased, and the greater part of the accidents occasioned by the contagion disappeared.

"Some time after, the same means were employed for destroying the contagion on board of the *Ratsevan*, and the *Revel* frigate, in which a malignant fever had also broke out.

"The success which Mr. Menzies obtained in these three instances left no doubt in his mind of the utility of the process which he had employed, and of the necessity of having recourse to it, whenever it should be necessary to purify the air of putrid miasmata.

"The same opinion was also adopted by Dr. Smith; for he concludes the report, in which the above-mentioned facts are related, with saying, That the experiments of Mr. Menzies, clearly establish two facts; in the first place, that the nitric acid has the power of destroying contagion; secondly, that it may be employed without producing troublesome effects upon the persons who respire it. He considers this discovery as being applicable to every kind of contagion, and even to that of the plague. Considered in this last point of view, he thinks it ought to interest every nation, &c.

"The beneficial effects of the nitric acid, seem to be as decidedly established as those of the muriatic; however, as Mr. Menzies very properly observes, the use of the nitric acid is only exempt from inconvenience, as long as we are able to reduce it into vapour, without its being converted into nitrous acid; for, otherwise, it would occasion accidents, which it would be difficult to remedy.

"Mr. Cruikshanks appears also to have employed acid fumigations; however, it is evident that he has given the preference to the oxygenated muriatic acid gas.

"The process which he employs for obtaining it is very simple: it consists in mixing accurately two parts of common salt, and one part of the black oxyd of manganese. After having diluted this mixture with a small quantity of water, concentrated sulphuric acid is gradually added to it. Immediately a large extrication of vapours takes place, which unite with the putrid effluvia in such a manner, that the air, in the place where the experiment is made, is soon found to be purified.

"In Spain, the fumigations with simple muriatic acid, reduced to the state of vapour, are generally adopted; and they are there considered to be so little capable of producing accidents, that they are performed even in chambers actually inhabited.

"Finally, it appears, that similar fumigations have frequently been practised in France, and that whenever they have been properly conducted, they have been attended with success.

"In the third part of his treatise, the author makes some reflections on the effects of acid fumigations, and examines the different opinions that have been advanced, in order to explain their mode of operation.

"The principal problem to be resolved in seeking the means of purifying a mass of infected air, was to find out agents that possessed the power of destroying the contagious miasmata, and particularly the putrid smell that always indicates their presence. It has been shewn, in the two first parts of this work, that some of the mineral acids had produced this two-fold effect; but it was useful to enquire, whether these acids acted in the same manner, and whether the results

which they presented were equally satisfactory. It was necessary also to ascertain, whether their operation ought to be attributed to oxygen; whether ammoniac formed an essential part of the putrid effluvia; whether they were always accompanied with carbonic acid gas; and, finally, whether the vegetable acids might not be employed with advantage.

"The solution of all these questions could not fail to throw a great deal of light upon the causes and immediate effects of contagion; the author, therefore, thought it an object that particularly demanded his attention. For this purpose, he instituted a course of experiments, both with a view to investigate the nature of the putrid miasmata, and to ascertain the mode of operation of the agents with which they are brought into contact.

"The infected air upon which he performed his experiments, was obtained from slices of raw beef, which he had expressly placed in a situation to putrify. This air, which possessed all the properties that were required, had scarcely been mixed with lime-water, when it immediately appeared that this was decomposed. The same circumstance took place with the solutions of the nitrates of silver and mercury; but, notwithstanding this decomposition, the fetid smell continued to be perceived as before.

"Slips of paper, stained with fernambour, the petals of mallows, curcuma, and a solution of copper, were suspended in vessels filled with the putrid air. After having remained there for the space of twenty-four hours, the colours appeared somewhat fainter, but they had undergone no change that indicated the presence of ammoniac.

"Several metallic oxids, such as that of zinc, the black oxyd of manganese, the brown oxyd of lead, &c. having been left for several days in contact with the same putrid gas, exhibited no change of colour, and had produced no disengagement of ammoniac.

"From the results of these, and several other similar experiments, the author draws the following inferences: 1. That air impregnated with putrid effluvia contains more carbonic acid than the ordinary air of the atmosphere. 2. That the effects of putrid air are entirely independent of the presence of carbonic acid; since, after the separation of this acid, the air still retains its putrid smell. 3. That putrid air does not contain ammoniac in a free state, as it does not change the colours of stained paper that is placed in it.

"These points being ascertained, Citizen Guyton subjected a certain quantity of putrid air to the test of the eudiometer; not so much with a view to determine its degree of salubrity, as to ascertain in what proportion oxygen gas was contained in it.

"The result of this second set of experiments soon proved, that the putrid air contained very nearly as much oxygen gas as the ordinary air of the atmosphere; and that, consequently, the deleterious effects of the putrid air ought not to be attributed to the deficiency of oxygen gas.

"The nature of the effluvia that rendered the air fetid, still remained to be investigated. In order to obtain a perfect knowledge of their nature, one must have been able to analyse these effluvia; but, unfortunately, the chemical means were found inadequate to the purpose.

"All that could be presumed was, that these putrid effluvia, being compound substances, must, like all other compound bodies, be susceptible of decomposition, whenever we present to them agents possessing greater affinity with one or more of their elements than these elements have with each other.

"Here also experiments were necessary, in order to ascertain in how far this idea might be founded. We shall soon

see how useful the results of those which Citizen Guyton has instituted for this purpose have been to him, and what advantages he has derived from them, in order to fix once for all the opinions that ought to be adopted, with respect to the choice of the means to be employed for disinfecting air vitiated by putrid miasmata.

"Convinced that the atmospheric air ought to be considered as serving merely as a vehicle to the putrid effluvia, the author brought fetid air into contact with various odorous vapours, such as are extricated during the combustion of benzoin, aromatic plants, &c. He afterwards strongly agitated another quantity of these putrid effluvia with the solutions of myrrh, benzoin, and balsam of Peru in alcohol. The result of all these trials was not satisfactory, for the putrid smell still continued to be perceptible.

"The same happened also with the pyro-lignous acid. Neither was the result more favourable, when he tried the detonation of gunpowder, at several times, in large vessels filled with putrid air; he only remarked, in this case, that a displacement of the mass of infected air was produced, but its qualities were not corrected.

"The result was not the same with the acetic acid; its action was speedy; for the putrid smell very soon ceased to be perceptible. He also tried the sulphuric and sulphureous acid. The first produced no change; the second was observed to have diminished the smell, but not to have removed it entirely.

"Besides the experiments which I have quoted, the author has attempted a great many more, which I shall pass over, as they proved altogether abortive; but there are some upon which I shall dwell, on account of their importance; I mean those that were made with the nitric, the simple muriatic, and the oxygenated muriatic acids.

"The greatest difficulty which Citizen Guyton had at first to surmount in this new kind of experiments, was to obtain the vapours of nitric acid free from nitrous gas; however, having at length, after a number of trials, obtained them such as he wanted, he immediately brought them into contact with the infected air. Upon afterwards examining this air, it did not appear to retain the smallest trace of a fetid odour.

"In order to establish the inference by a comparison of the results in circumstances perfectly similar, he afterwards subjected the muriatic acid to precisely the same experiments. In this case also the fetid smell was completely destroyed.

"Finally, the oxygenated muriatic acid acted in so decided a manner upon the putrid air, that from the moment when it was mixed with it, the putrid smell ceased to be perceptible.

"When we reflect upon the experiments that have been recorded, it is easy to see, that, if their results have not all been equally satisfactory, they may at least serve to point out the agents in which we may place some confidence, and enable us to choose those whose power of destroying putridity appears the most decided.

"The only means of determining our choice of such agents would, undoubtedly, be to compare the effects produced by the different agents that were employed in the above-mentioned experiments.

"Those produced by the use of perfumes, vinegar, the detonation of gunpowder, the pyro-lignous acid, the sulphurous and sulphuric acids, &c. were, as has been seen, either none at all, or tardy, or of little efficacy. The acetic and nitric acids have appeared to act in a very decided manner; but the difficulty of obtaining them in that state, in which it is

necessary they should be, in order to produce such favourable effects, is a considerable objection against their use.

"The same is not the case with the simple muriatic acid; the facility with which it is reduced into vapour, the great expansibility of this gas, and above all, the promptitude of its operation upon the putrid miasmata, shew of how great importance it is not to neglect its use.

"However, adds the author, I have the satisfaction of announcing, that this is not yet the most powerful means with which the progress of chemistry has furnished us for resisting contagion. The oxygenated muriatic acid is, beyond all contradiction, the most certain specific, and the most ready preservative which we can employ against it.

"It seems that, after having entered into the discussion of all the subjects in question, Citizen Guyton might have presented the public with the general conclusion of his treatise: however, he thought it still incumbent upon him to examine the influence which oxygen might exert of itself in the process of disinfection, and to enquire whether all kinds of contagious miasmata were equally subject to the operation of the same agents.

"Since chemistry has made us acquainted with the particular nature and properties of oxygen, it was soon found that it possesses a great disposition to combine with various substances, and particularly animal matter. The constant observations that have been made upon this subject have led to the supposition, that oxygen might be employed as a medicine.

"In fact, it is certain that medicines act only by inducing changes in the body, that tend to attenuate the morbid matter, and re-establish the order and regularity of the animal functions; it must also be allowed, that oxygen, as it possesses such properties, must be a real medicinal substance, and that, in order that it may act with efficacy, it is only necessary to employ it in a state of appropriation that may ensure its success.

"This fact is at present so well demonstrated, that several physicians of the highest reputation are inclined to admit of only two species of medicines, namely, the *super-oxygenating* and the *disoxygenating*; the action of which they explain by saying, that they *burn* or *unburn* (*brûlent* on *débrûlent*) the bodies with which they are brought into contact; meaning, that they furnish them with the oxygen which they want, or deprive them of that which they possess in too large a proportion.

"The expression of *burning*, employed in order to account for the manner in which medicines operate, as forced as it may appear, will be acknowledged to be strictly just, when we consider that, besides the combustions that take place with rapidity and an extrication of heat, there are also others which go on slowly, but the effects of which are perfectly similar to those of the former.

"Both in the one and the other, it is always the oxygen which tends to combine itself, and which, according to its greater or less degree of affinity with the body with which it unites, entirely changes the form of this body, its weight, its taste, and its colour, and at last imparts to it properties which it did not possess before.

"According to this explanation, it is easy to see that the alterations which animal substances incessantly undergo are, in fact, the effects of combustions, slow indeed, but which may, in some degree, be accelerated by presenting these same substances with a large quantity of oxygen at once, or placing them in contact with bodies, which, containing a large quantity of this principle, may easily yield to them a portion of it.

"It was a similar theory, which led, almost naturally, to

the medicinal use of oxygenated fats, nitric acid, oxygenated muriatic acid, the super-oxygenated muriate of pot-ash, and various other oxygenated substances, the sure effects of which afford the means of combating a variety of maladies, to the progress of which medicine had before no remedy to oppose, or could only cure with a great deal of difficulty.

"Since, therefore, it is impossible to deny the power which oxygen incessantly exercises upon animal substances, it must also be admitted, that the putrid effluvia that exhale from these same substances must also be subject to the action of this agent, and that, by combining with it, they must necessarily acquire new properties.

"In order to explain more at large his ideas with respect to this subject, the author has thought proper to treat of the oxygenating substances, and particularly the oxygenated muriatic acid, considered only as preservatives against contagion.

"It is a fact universally admitted, that among persons the most exposed to the influence of contagious maladies, there are some upon whom they produce no bad effects. Great pains have been taken, and always in vain, to explain the cause of so singular a circumstance. But, says Citizen Guyton, what need is there to have recourse to abstract theories, or even to enquire at all into the causes of a change of properties that does not exist, when the resistance, which some persons shew towards the morbid matter, may be explained in a simple and purely chemical manner, from its analogy with one of those general phenomena which are daily exemplified before our eyes in an infinite variety of operations?

"Let us take an example, he adds. We know with what facility the sulphuric acid attacks aluminous earth. This earth, however, is susceptible of a state of aggregation, in which it resists all combination, without there being the smallest ground to suspect that it has undergone any alteration in its nature. Might it not also be the same with the human body? and might we not assert that a certain state of health is connected with a state of aggregation, that resists that combination of the contagious miasmata with the body, which would take place if the force of aggregation were different?

"Moreover, this explanation seems to accord with facts, which various observations that are constantly made have enabled us to collect. It is known that the best means of guarding one's self against the impression of contagious miasmata, when we cannot remove ourselves out of the infectious atmosphere, is to support, and even augment, the vital powers: now, as the oxygenating substances possess this property in the highest degree, it is evident what great advantage may result from their use, and how much those especially deserve the preference, which, like the oxygenated muriatic acid, may easily be reduced into the state of gas.

"Carried thus, by respiration, into the nasal and pulmonary cavities, disseminated in the ambient atmosphere, or introduced, by respiration, into the stomach, acting finally upon the whole surface of the body, they operate as a stimulant, which augments the activity of the organs, excites their sensibility, and soon puts a stop to the effects of the miasmata, which, in general, act only by debilitating.

"Under this point of view, Citizen Guyton has considered the mode of operation of the oxygenating substances. This efficacy appeared to him to be so well demonstrated by theory and experience, that he presumes that those who reflect upon the subject will no longer fear the appearance of contagion, as they will be sure of having the means of guarding themselves against it.

"One grand question, however, still remained to be decided. It was necessary to ascertain, whether the anti-con-

tagious agents that were proposed as capable of producing such salutary effects, were applicable to all the different kinds of contagion.

"The author admits, without hesitation, that it would be contradictory to all evidence to suppose that all the maladies which a sick person can communicate to a healthy one, have the same matter for their cause.

"However, admitting the distinction that has been justly established between the maladies that proceed from certain effluvia suspended in the atmosphere, and those which are only contracted from the immediate contact of a matter sometimes also invisible, but more fixed; it must also be allowed, upon the authority of unequivocal observations, that the first are those which prevail the most frequently, against which it is the most difficult to guard one's self, and against which, consequently, the necessity of preservatives and anti-contagious remedies is the most urgent. To this class belong the fevers of hospitals, jails, and ships, and that which occurs in the vicinity of marshes; in a word, all those malignant fevers which owe their origin to putrid exhalations.

"As to the maladies of the second class, that can only be contracted by immediate contact; it is also admitted that they originate from the presence of some virus, which assuredly is not a simple substance, but rather a compound body, which must be subject to the condition which obtains in all its products, namely, that of undergoing combustion, whenever it is brought into contact with oxygen. Hence it appears, that we have already reason to presume that the virus of diseases must experience great changes from the action of the oxygenating substances, and that consequently their properties must necessarily be altered.

"To substantiate this conclusion, the author adduces the following facts. The variolous virus is certainly one of those, the specific contagion of which is the most distinctly characterized; however, it is certain, according to the experiments of Mr. Cruikshank, that a portion of this virus, mixed with oxygenated muriatic acid, produced no effect, when it was attempted to inoculate with it; whilst another portion, with which none of the acid had been mixed, communicated the variolous contagion.

"It is also known, from practical observations, that the syphilitic virus is destroyed by oxygenated mercurial remedies, and that it produces no infection; whilst the matter taken from the same ulcer, without such admixture, produces a chancre, and other venereal symptoms.

"The hydrophobia, which has hitherto been considered as incurable when the malady makes a rapid progress, may, however, be attacked with success, by touching the wound that has been made by the rabid animal, with powerful oxygenating substances, before the local nervous irritation has produced the rabid fever.

"Finally, the pŕŕic virus may also be destroyed by the oxygenating remedies; the effects of which, in these cases, are so well known, as to have no manner of doubt respecting the subject.

"It cannot indeed be denied, that it has not been demonstrated with the same degree of evidence, that the oxygenating remedies are capable of acting with equal efficacy upon the virus of the plague, as experiments have not yet been made upon this subject; but, if it be permitted us to draw conclusions from mere probabilities, we may assert, that this virus, being undoubtedly a compound substance, must undergo, by the action of oxygen, a combustion which, whilst it changes its nature, must also change its deleterious properties.

"From what has preceded it will be seen, that the author has done all in his power to make known those means of disin-

fection which appeared to him capable of producing such important effects; but, in order to enable his readers to judge for themselves of the utility of those processes, which, before those which he has pointed out, were in some degree of reputation, he has compared them together, and assigned to each that rank in the scale of utility to which it is entitled.

"From this comparison, which is comprised in the third part of the work, it appears:

1. "That cold water, lime, resinous substances, the kindling of fires, the burning of simple and aromatic vinegar by throwing it upon red-hot coals, the detonation of gunpowder, &c. ought not to be considered as real preservatives and anti-contagious remedies, as they do not possess the power of decomposing the putrid miasmata.

2. "That ordinary vinegar possesses, indeed, the power of decomposing the miasmata; but that this power does not exert itself in a perceptible manner, unless the infected substances are immersed in this acid, or are capable of being washed with large quantities of it.

3. "That radical vinegar, or acetic acid, produces effects sufficiently rapid; but that the difficulty of obtaining it in large quantities, at a moderate expence, will frequently be an objection against its use.

4. "That the sulphuric acid, on account of its great fixity, is not capable of contributing to the disinfection of the air.

5. "That the nitric acid is very capable of destroying the putrid miasmata, but that the use of this remedy is still attended with some inconvenience, owing to the impracticability of entirely depriving it of nitrous gas, the action of which is always prejudicial to the health of those who respire it.

6. "That the muriatic acid, on account of the prodigious expansibility of its vapours, which enables them to reach every part of the substance upon which we wish to operate, affords us very great advantages.

7. "Finally, that the oxygenated muriatic acid justly deserves the preference over all the other remedies, not only on account of the promptitude and facility with which it is everywhere diffused, but also because its action is always certain, and it immediately destroys all the putrid miasmata, that are either floating in the atmosphere, or fixed upon bodies.

"I think I have said sufficient to enable the reader to form an idea of the work which Citizen Guyton has presented to the public. I shall only add, that it would be difficult to treat a subject, like that which forms the argument of this work, in a more methodical, perspicuous, and, above all, in a more interesting manner.

"All the facts which the author has adduced, are substantiated by vouchers that cannot leave the smallest doubt of their authenticity; all the experiments which he has recorded have been performed with care and accuracy; and the inferences which he has drawn from their results are just, and little subject to objection; finally, it appears to me, from all these reasons, that the work of Citizen Guyton ought to be gratefully welcomed by all those who, alarmed at the ravages unfortunately too frequently produced by contagious diseases, have ardently wished that means might be discovered for putting an end to the devastations occasioned by these scourges of the human race.

"What is still to be wished is, that the work of Citizen Guyton may obtain all that publicity which it merits; and that particularly physicians, and in general all whose professional duty it is to watch over the health of their fellow-citizens, may receive such a conviction of the efficacy of the means here proposed, as no longer to hesitate in recommending them to be put in practice. The success with which

they would be attended would soon afford sufficient motives of encouragement; and, convinced then of the utility of Citizen Guyton's method, they would unite with all the friends to humanity in paying him that tribute of gratitude which his labours have deserved."

INGELMUNSTER, or **ENGELMUNSTER**, a village of Flanders, where is a castle, which was often made a garrison in the religious wars of the sixteenth century. It is situate near the river Mandel, five miles N. of Courtray.

INGLING, a town of France, in the department of Moselle, six miles E. of Thionville. Long. 6. 22. E. Lat. 46. 22. N.

INGRANDE, a town of France, in the department of Mayne and Loire, situate on the Loire, 15 miles W.S.W. of Angers. Long. o. 25. W. Lat. 47. 23. N.

INK (*Encycl.*). M. Ribaucourt, in the "*Annales de Chimie*," directs eight ounces of Aleppo galls, and four ounces of logwood, to be boiled in twelve pounds of water, till the quantity is reduced to one half; when the liquor should be strained through a linen or hair sieve into a proper vessel. Four ounces of sulphate of iron (green vitriol), three ounces of gum-arabic, one ounce of sulphate of copper (blue vitriol), and a similar quantity of sugar-candy, are now to be added: the liquid should be frequently shaken, to facilitate the solution of the salts. As soon as these ingredients are perfectly dissolved, the composition is suffered to subside for twenty-four hours; when the ink may be decanted from the gross sediment, and preserved for use in glass or stone bottles, well stoppered.

This ink exhibits a purplish-black colour in the bottles; but the writing performed with it, is said to be of a beautiful black cast, which it retains, unaltered, for a considerable length of time. Each quart of the preparation contains:

	oz.	drs.	grs.
Of Galls	-	-	2 5 20
Green vitriol	-	-	1 2 40
Logwood	-	-	1 2 40
Gum	-	-	1 0 0
Blue vitriol	-	-	0 2 40
Sugar-candy	-	-	0 2 40

M. Ribaucourt is of opinion, that ink thus prepared, may be preserved several years in a state of perfection, without depositing either galls or iron.

INOCULATION (*Encycl.*). See Cow-Fox, *Supp.*

INNICHEN, a town of Germany, in the Tyrol, situate on the Drave, 29 miles E. of Brixen. Long. 12. 17. E. Lat. 46. 48. N.

INSECTS (*Encycl.*). Dr. Darwin is of opinion, that the most ingenious, as well as the most effectual, method of preventing the depredations of insects, consists in artificially propagating the larvæ of the aphidivorous fly, of which we have given a representation in pl. 33, and which has been observed by naturalists to deposit its eggs where the aphids abound.

As soon as the larvæ are produced, they devour the aphides around them, seizing the latter in their mouth, as delineated in the plate, and extracting their juices. We have not been able to ascertain their exact duration in a caterpillar state, but believe that in about a fortnight they contract, and attach themselves to some solid matter, by means of a little gluten which is discharged from their mouth; and are thus converted into *chrysalides* or *nymphe*, as above represented. In this state, the insect continues 10 or 11 days, when it bursts its cell, and gives a perfect fly, of which likewise a delineation is given at a.

If these insects could be collected, carefully preserved during the winter season, and properly disposed on nectarine and peach-trees, early in the spring, Dr. Darwin thinks it is

probable that the depredations of the blite might be counteracted, "by the natural means of devouring one insect by another; as the serpent of Moses devoured those of the magicians."

A kind of bellows has been invented by Mr. Green, of her majesty's flower-garden, Kew, for the purpose of destroying the red spider, and other noxious insects in hot-houses and plineries, with the fumes of burning tobacco. The same noxious vermin may likewise be exterminated by burning (when the hot-house is shut) matches moistened with a spirituous tincture of asa-fetida, and rolled in a powder consisting of equal parts of sulphur and Scotch snuff. It will also be of service to wash the frames of hot-houses, &c. with four ounces of sublimate, dissolved in two gallons of water; but this operation should be performed with the utmost caution, on account of the corrosive properties of the mercury.

In the *Annales de Chimie*, M. Tatin gives an account of a compound which he has successfully used for exterminating insects. He directs 1½ of a lb. of the best black soap, a similar quantity of flowers of sulphur, 2 lbs. of any kind of mushrooms, and 15 gallons of rain or river water, to be employed. The fluid is to be divided into two equal parts, one of which is put into a barrel, together with the soap and mushrooms, after the latter have been somewhat bruised. The other half is to be boiled in a kettle with the sulphur inclosed in a bag, and fixed to the bottom of the vessel, by means of a stone or other weight.

These ingredients are to be boiled 20 minutes, during which the sulphur should be well agitated with a stick, that the water may be the better impregnated. When the liquid is taken from the fire, it is to be poured into the barrel, and stirred daily, till the mixture become in a high degree fetid: for, the older and stronger the composition is, the more speedy and powerful will be its effects. The liquor is to be sprinkled on the plants infested with insects; great numbers of which it destroys on the first application: it will, however, be necessary to repeat the asperision, in order to exterminate ants, or other vermin that breed beneath the soil; and, for this purpose, from two to eight pints are required, according to the depth and extent of their nests.

Although insects are very injurious to vegetation, yet Dr. Darwin is of opinion that they may be rendered extensively useful as a manure. Hence, in the summer months, he recommends heaps of dung to be supplied with water, for promoting the propagation and nourishment of myriads of vermin; which, when suffered to decay on the soil, would greatly contribute to its fertility.

In a recent publication, entitled, "*Illustratio Iconographica Insectorum*," &c. Mr. Fabricius has described several new insects, which he saw in the different collections at Paris. His descriptions, however, being not always sufficient for determining the species he had in view, the great difficulties hence arising can only be removed by good figures of the originals, signed by his hand; by which means these objects will, as it were, be multiplied and perpetuated, and which, if once destroyed, may perhaps not be found again. It is therefore incumbent upon us to do proper justice to the zeal and merit of Cit. Coquebert, author of the work we are here announcing, which consists in representing by figures, coloured after his own drawings, the insects observed in the Paris cabinets, and described by Mr. Fabricius; in adding the description and synonymous terms of that naturalist; and in publishing other new species, or those that are less known. The celebrated artists, Cit. Maleuvre for engraving, and Didot the elder for the typographical part, have assisted in this interesting work; and seconded the pencil of a man, who knows how necessary it is to observe and study nature, before he at-

tempts to copy her. The 10 first plates contain about 120 figures, a great number of which present the insects in detail. He begins with those that are particularly subject to be destroyed, belonging at the same time to less numerous classes than others, viz. the *Synitotes*, *Pezotes*, and *Rynogotes* of Fabricius. North America, Cayenne, the Barbary states, and the south of France, are the principal countries from which the species he has figured are brought. The new genera of Delphax, Oryflus, and Plocus, are there figured, with an accurate representation of their organs of manducation, in which he has been much assisted by Cit. Latraille, to whom the plate is entirely owing of the little known genus Plocus, which on account of their minuteness and fugacity, had hitherto escaped the observation of naturalists. Some anatomical observations, new synonymous terms, and other remarks, give an additional value to this work; and we are convinced that it will meet with the most favourable reception by every naturalist and amateur.

INSTERBURG, a town of Prussian Lithuania, containing about 3000 inhabitants. Corn and beer are the principal articles of trade. It is 44 miles E. of Konigsburg. Long. 21. 40. E. Lat. 54. 40. N.

INSTITUTE, the French name for a national school or academy in Paris, having, if we may credit its own reports, and those of its founders, high claims to superiority and distinction. When royalty was abolished in France, it would have been inconsistent to continue the titles Royal Academy of Sciences, Royal Academy of Inscriptions, &c.; but instead of merely abolishing the word royal, and substituting national in its stead, it was thought a prudent measure to abolish the seven academies themselves, or rather to melt them all down into one great academy; to which was given the appellation of the *National Institute*. This academy, founded on a decree of the new constitution, was opened on the 7th of December, 1795, when Benezec, the then minister for the home department, attended, and the following decree of foundation was read:

"The Academy of Arts and Sciences belongs to the whole republic, and Paris is its place of residence. Its employment is to aim at bringing all arts and sciences to the utmost perfection of which they are capable. It is to notice every new attempt, and all new discoveries, and to keep up a correspondence with all foreign literary societies. And by the particular orders of the Executive Directory, its first studies are to be directed to those subjects which more immediately tend to the reputation and advantage of the French republic."

The academy, which is not yet completely formed, is to consist of 288 members, half of whom are to reside in Paris, the other half in the departments; and to them is to be added a certain number of foreigners, as honorary members, confined at present to twenty-four.

The academy is divided into three classes, each class into sections, each section to contain twelve members; viz. 1st class. Mathematics and natural philosophy. This class is divided into ten sections. 1. Mathematics. 2. Mechanical arts. 3. Astronomy. 4. Experimental philosophy. 5. Chemistry. 6. Natural history. 7. Botany. 8. Anatomy and animal history. 9. Medicine and surgery. 10. Animal economy, and the veterinary science. 2d class. Morality and politics. This class consists of six sections. 1. Analysis of sensations and ideas. 2. Morals. 3. Legislation. 4. Political economy. 5. History. 6. Geography. 3d class. Literature and the fine arts. This class consists of eight sections. 1. Universal grammar. 2. Ancient languages. 3. Poetry. 4. Antiquities. 5. Painting. 6. Sculpture. 7. Architecture. 8. Music.

For each class a particular room in the Louvre is appropriated. No one can be a member of two classes at the same time, but a member of one class may be present at the meet-

ings of any other. Each class is to give to the public, yearly, an account of its transactions.

Four times a-year there are public meetings. On these occasions, the three classes meet together. At the end of each year, they give a circumstantial account to the legislative body of the progress made in that year in the arts and sciences. The prizes given yearly by each class are publicly notified at certain times. The sums requisite for the support of the institution are decreed yearly by the legislative body, upon a requisition made by the government.

The first forty-eight members were chosen by the Executive Directory, to whom the choice of the remaining members was confined. To the members, resident in Paris, is reserved the choice both of the department and foreign members. On a vacancy in any class, three candidates are named by the class for the choice of the body at large.

Each class is to have, at its place of meeting, a collection of the products, both of nature and art, and a library, according to its particular wants. The regulations of the institution, with respect to the times of meetings, and its emplacements, are to be drawn up by the body at large, and laid before the legislative assembly. The hall in which the body at large holds its meeting, forms part of the west wing of the Old Louvre, at present called the Museum. It formerly went by the appellation of the Hall of Antiques (*Salle des Antiques*); and as long as the kings of France inhabited this part of the palace, was occupied by their guards, from which circumstance it obtained the name of the *Hall des Cent Suisses*. It was likewise appropriated to banquets and entertainments, given by the court on gala days; and it was to this place that Henry IV. was conveyed, on his assassination by Ravallac. It was built at the same time with the rest of this part of the Louvre, about the year 1528, after the designs of Pierre Lescot, abbot of Clagny. It is 144 feet in length, and 40 in breadth, and holds from 1000 to 1200 persons. In order to adapt it to its new destination, the floor has been sunk, which gives a greater air of lightness to the roof. In the centre stands a double table, in the form of a horse-shoe, supported by sphinxes, at which the members of the Institute take their seats. This table is surrounded by two tiers of benches, which are raised for the accommodation of spectators, who have likewise seats provided for them in the vast embrasures of the windows, and at each extremity of the hall.

Whether science will be essentially advanced by this innovation, time must determine; but candour compels us to acknowledge, that thus far the proceedings of the National Institute have been abundantly interesting.

INSTRUCTION, NATIONAL, a novel establishment of the French republicans, proposed with a view of making the rising generation in France all that its founders can wish, in politics, in morals, and with regard to religion; and thus give permanency to the new order of things. When Christianity was abolished in France, it was impossible to continue the universities and other seminaries which were founded by Christians, and obliged by their constitution to teach, whether pure or not, the doctrines of Christianity. They were accordingly all swept away, and a new system of education planned, which was to be carried on in what they call

The Primary Schools.

The Central Schools.

The School of Health.

The School of Oriental Languages.

The Polytechnic School.

The National Institute.

The Jury of Public Instruction.

The Commission of Public Instruction.

The Legislative Committee of Instruction. And various

other national establishments for the improvement of particular sciences.

The first degree of public instruction is to be met with in the *Ecoles Primaires*, established by a decree of the convention of the second *Pluviose*, in the second year of the republic. Every district is furnished with one of these schools; the professors or masters in which are paid from the national treasury; and to which every head of a family, without exception, is compelled by law to send its children for instruction. The subjects taught in these primary or elementary schools are divided into nine classes:

1st, Instructions connected with the physical and moral situation of children, prior to their entering into these schools. 2^d, Similar instructions as a guide to teachers in the national schools. 3^d, The arts of reading and writing. 4th, The elements of French grammar. 5th, Elements of arithmetic and geometry, with the theory of the new menuration. 6th, The elements of geography. 7th, Explanations of the principal phenomena and productions of nature. 8th, Elements of agriculture. 9th, Elements of republican morals.

Next to the primary schools in rank and consequence are the *Ecoles Centrales*, which were established by a decree of the Convention of the seventh *Ventose* in the third year. They are situated in the capital of every department, bearing the proportion of one central school to 300,000 inhabitants. In these schools the republican youths are taught the sciences, and their application in real life. In each of them are professors for the following branches: 1. For mathematics. 2. Experimental philosophy and chemistry. 3. Natural history. 4. Agriculture and commerce. 5. Logic and metaphysics. 6. Political economy and legislation. 7. The philosophical history of nations. 8. The art of healing. 9. Arts and manufactures. 10. Universal grammar. 11. The belles lettres. 12. The ancient languages. 13. The modern languages. 14. The fine arts.

Each central school is furnished with an extensive public library—a botanic garden—a cabinet of natural history—an apparatus for experimental philosophy—and a collection of machines and models connected with the arts and manufactures.

The professors of each school hold, every month, a public sitting, in which conferences are held relative to subjects connected with the improvement of letters, the sciences, and the arts, which are the most beneficial to society.

The object in the establishment of the primary and central schools was, the general instruction of all classes of the citizens; and it being incompatible with the perfect completion of that important purpose, to expect from them the propagation of particular branches of science, it became necessary to establish other literary and scientific academies. Accordingly, the French government have founded,

1st, Schools of health (*les écoles de santé*), in Paris, Strasbourg, and Montpellier, where medicine and surgery are studied; which schools are affirmed, by those who find nothing wrong in France, to be the most perfect of their kind, as well as new and unparalleled models for such institutions.

2^d, Two schools for *Oriental languages*, in the national library, and in the college of France.

3^d, The *Polytechnic* school in Paris, or central school for the direction of public works. This establishment is very generally admired, and considered as a model for imitation. It contains more than 400 young persons, previously educated in the mathematics, and the majority of them intended for engineers in various lines; and they labour under the immediate direction of their tutors nine hours every day. It occupies the principal part of the *Palais de Bourbon* in Paris,

and is furnished with a large collection of instruments and models. The journal of the Polytechnic school, which is published by the booksellers Regent and Bertrand at Paris, is a perfectly original work, and admirably calculated to convey useful information.

Of the National Institute a sufficient account has been given in the preceding article. We proceed therefore to the jury of public instruction (*Le Jury Central d'Instruction*), of which the principal business is to superintend the primary and central schools. It appoints the professors in the schools, and examines into their conduct. Like the legislative body, it is renewed by at third every half-year. When they have chosen a professor for a central school, they submit their choice to the department; and, in case of disapprobation, they make another appointment. To this jury of public instruction the professors in the central schools are amenable for all misconduct connected with their offices; it may expel them, but all its decisions must be submitted for confirmation to the tribunal of the department.

There is also established at Paris a supreme council, called *The Commission of Public Instruction*, to which is entrusted the whole executive department. The preservation of the national monuments, of public libraries, museums, cabinets, and valuable collections; the superintendence of all the schools and the modes of instruction; all new inventions and scientific discoveries; the regulation of weights and measures, national statistics, and political economy; are all placed under the authority of this supreme commission. For the commodious and regular execution of so many complicated branches of business, there is a large office, called *Le Secrétariat*, which is divided into three departments. 1. For the regulation of the different kinds of instruction; of the modes of education in the schools; and for the choice of elementary books. 2. For weights and measures; inventions and discoveries; libraries and bibliography; museums, works of art, and literary rewards and encouragements. 3. For theatres, national feasts, republican institutions, and the erection of monuments.

As all public establishments require the superintendence and occasional correction of the legislature, in addition to that of their own immediate executive authority, it has been deemed necessary to appoint a permanent committee of instruction in the legislative body, to provide such sums as may be necessary for the preservation and improvement of this system of instruction. This legislative committee are invested with due authority for these purposes. Their objects are precisely the same as those of the commission of public instruction above described, only with this difference, that the latter superintends the execution of existing laws, whilst the former receives and improves them, or proposes new ones. This committee is divided into three departments, as is the commission, with exactly the same arrangement of their respective labours. The committee being charged with the enactment of all new laws, its members, with a view to obtain accurately all the requisite information relative to the numerous branches of the arts, have procured from the legislative body the appointment of a *commission temporaire des arts* to be annexed to them, and to meet in the same house with them; which temporary commission is divided into sixteen classes: viz. 1. For Zoology; 2. Botany; 3. Mineralogy; 4. Physics; 5. Chemistry; 6. Anatomy; 7. Machinery; 8. Geography; 9. Artillery and Fortification; 10. Medals and antiquities; 11. Bibliography; 12. Painting; 13. Architecture; 14. Sculpture; 15. Bridges and causeways; and, 16. Musical Instruments.

The improvements of the national literary and scientific establishments are numerous and important.

1st, By a decree of the convention of the 11th *Prairial*, in

the second year, it was enacted, that means should be adopted by which every possible advantage might be derived from the botanic gardens of the republic, in Turkey and other foreign countries. This politic decree clearly tended to render France, in the language of the reporter, *L'abregé de tous les climats, et l'entrepôt de l'Europe*—"The epitome of every climate, and the magazine of Europe." Those plants which thrive between the tropics may be cultivated in the south of France; and those which are the produce of northern climates, may be cultivated in the northern departments; by which means, France will be in possession of all foreign plants and drugs, without the exportation of specie.

2d, The National Bibliography was decreed in the sitting of the 22d *Germinal*, in the second year. It consists of a complete catalogue of books of all descriptions, the property of the nation; it was then ascertained, that the republic possessed more than ten millions of books. The titles of them were to be adjusted by actual comparisons; the manuscripts to be registered separately; anonymous productions were to be arranged according to their subjects; and those of known authors in the alphabetical order of the names. The several editions to be classed according to their dates: and what may be deemed more important, this French National Bibliography will contain a dictionary of anonymous books, as well as those published under fictitious names, a desideratum in the republic of letters.

3d, The annihilation of all *patois*, or dialects, decreed in the 16th *Prairial*, in the second year. Notwithstanding the universality of the French language, and that it was exclusively spoken in the majority of the inland departments, yet there existed thirty various dialects in France. It is more astonishing that Rozier had remarked, that between one neighbouring village and another, there was so considerable a difference in the dialect, that the inhabitants could not understand each other; and the vinestock had thirty different names. The naturalist, Villars, has flated that in the nomenclature of vegetables, in the departments, he had only met with an hundred which had a common appellation.

4th, The establishment of the *Conservatoire des Arts et Métiers*, was decreed in the sitting of the 8th of *Vendémiaire*, in the third year. This consists of a spacious hall, in the form of an amphitheatre, and contains the instruments and the models of machinery connected with the arts, and a description of their uses, with every book relating to them. Annexed to this establishment are three expositors and a draughtsman, who explain to the students the use of each instrument, and who register every new discovery, which is presented to the *Bureau de Consultation*, to the Lyceum of Arts, the *ci-devant* Academy of Sciences, or to the Board of Commerce.

5th, The establishment of the Board of Longitude was decreed in the sitting of the 7th of *Messidor*, third year. It was certainly a disgrace under the monarchy, that an astronomical and nautical establishment, which had already proved so beneficial to Great Britain, should not have been adopted in France. In consequence of this decree, the French board is now as complete as the English. It consists of ten members, and has under its jurisdiction the national observatory at Paris, and all the astronomical instruments belonging to the republic. It corresponds with foreign astronomers; delivers public lectures on astronomy and navigation; and its proceedings are annually recited in a public sitting.

6th, The general school of the Oriental languages was established by a decree of the 10th of *Germinal*, in the fourth year. This school adjoins to the national library, and all the books and manuscripts relative to Oriental literature are deposited in it.

7th, The National Museum of Antiquities was decreed in the sitting of 20th of *Prairial*, fourth year. A school of this description was successfully established at Vienna, by Eckel; at Gottingen, by Heyne; at Leipsick, by Emeit; and even at Strasburgh, by the celebrated Obelin: Paris was, however, without one. This national archeology, or science of antiquity, is divided into nine different classes: inscriptions, characters, statues, *bas-reliefs*, sculptures, paintings, mosaics, medals, civil, religious, and military instruments. This extensive establishment is under the direction of two principal professors; *le Conservateur Professeur*, and *le Conservateur Bibliothécaire*. The province of the former is to deliver public lectures on the several branches of antiquities, to teach the theory of medals and engravings, the history of the arts among the ancients, &c. The duties of the latter are merely of a bibliographical nature.

8th, The new modelling of the Grand National Library, was decreed in the sitting of the 25th *Vendémiaire*, in the fourth year. By virtue of this decree, the place of librarian in chief was suppressed, and the whole establishment placed under a *conservatoire* of eight members; of whom two were appointed for the superintendence of printed books; two for manuscripts; two for antiquities; and two for engravings. From these a temporary director is annually chosen, who superintends the whole, acts occasionally as president of this assembly, and maintains a regular correspondence with the constituted authorities relative to the concerns of the library.

9th, The augmentation of the Museum of Natural History, formerly called *Le Jardin Royal des Plantes*. This establishment was decreed the 15th *Brumaire*, third year, upon a report of Thibadeau, in the name of the committee of Public Instruction. Besides the addition of large rooms, and various other buildings, there are new collections of natural curiosities and productions; and the library is much increased. It is open to the public three times a-week. At stated periods all the naturalists in Paris deliver courses of lectures in the various branches of natural history. The museum is said to have received greater improvements from this augmentation than from all the labours of Buffon, or from its foundation, since the time of Tournesot.

10th, The *Ecole des Mines*, was established in the *Hôtel des Monnaies*, and has for its direction the naturalist Le Sage. This institution is unrivalled in Europe; and the collection of mineralogical curiosities surpasses whatever can be conceived.

11th, The Society of Natural History in Paris, deservedly classes among those which have rendered the greatest services to the cause of science since the revolution. A lecture of public instruction is held every ten days, which is generally given by one of the members, and which is open to all the lovers of natural history. Premiums are proposed for dissertations; one of which, by the late C. Herman, jun. (whose early decease was a great loss to the republic of letters), on the *apterous* class of insects, may be said to constitute an epocha in the annals of natural history. The society has published a volume of memoirs, in folio, entitled, "*Transactions of the Society of Natural History*." It has likewise erected a statue to the great Linnæus, in the national garden of plants; and, at the period when every public instruction was suspended, gave lectures on the different branches of science belonging to its department. Several intelligent and skilful navigators, among others those sent in search of the unfortunate La Pérouse, as well as those which accompanied Buonaparte on his expedition to Egypt, were members of this society.

This account of the present state of public instruction, the sciences, the arts, and the progress of national literature, in

France, has been taken from a miscellany, the principal writers of which call it a *sublime* system; and seem to consider the increase of the national library, the improvement of the botanic gardens, and the discoveries that have been made by the different schools or institutes, as furnishing a demonstration that the republican government is more favourable to the advancement of science, than the monarchical, whether absolute or limited. But it should not be forgotten, that this system is yet in its infancy; and that in prosecuting new schemes, all men, and more especially Frenchmen, are actuated by an enthusiasm which gradually cools as their pursuits become familiar. We therefore rather wish than expect that the progress of science in that country will be more rapid than it was under the monarchy.

That something may be learned from this system to improve the modes of education in other countries it would be illiberal and uncanid to doubt; but its almost total neglect of what is most valuable in education, the *culture of the heart*, and, above all, the silence observed with regard to *RELIGION*, which is the only *BASIS of private happiness and public welfare*, are defects too glaring to pass unobserved by the most inconsiderate reader.

INSTITUTION, ROYAL, a new establishment in London, set on foot for the distinct purpose of applying science to the common purposes of life.

In January, 1799, a committee was appointed by the Society for bettering the Condition of the Poor, &c. to confer with Count Rumford on the formation of an institution; which, besides having a general view to the benefit of arts and manufactures, and to the advancement of taste and science, in this country, should specifically direct itself to the improvement of the *means of industry and of domestic comfort among the poor*. Though the society has had reason to flatter itself that considerable benefit had been diffused among the general mass of the people by its labours, yet difficulties have impeded the progress of any considerable melioration in the *diet and domestic habits* of the poor; and there appeared very little prospect of those difficulties being removed, until a *centre of action* could be fixed, to which persons might apply for examples,—for models,—and for engravings, accompanied by printed instructions; without being any longer compelled implicitly to rely on the talents, the docility, and the conscientious moderation, of the different tradesmen, who might be employed to make and sell them.

It appeared very evident that an establishment of this nature, if on a scale calculated to be extensively useful, must embrace too great a variety of objects, and be far too interesting and too important, to be annexed to the society for the poor, or to any other existing society. The committee therefore was of opinion that, after they obtained from Count Rumford the original sketch or outline of the plan, and had engaged him to take an active and leading part in the conduct and execution of it (their own members giving their individual support to the measure), nothing further remained to be done on the part of the society.

The models and inventions, in which the poor are most immediately concerned, will be those which may promote economy in food and fuel, and tend to correct and purify the air in cottages, and also in workhouses, hospitals, manufactories, and in all public buildings; and which may furnish means and instruments of industry, on a cheap and simple construction; so as to afford the cottager and his family thriving and healthful occupation at home during bad weather, or at times when proper employment is not to be obtained abroad. The supply of such means and instruments of industry has been long, and anxiously, desired by the friends of the poor. Many heavy and solitary hours might then be occupied with

pleasing employment; and the cottager would thereby be enabled to educate his children in those *regular and even habits of industry and attention*, which, when securely and permanently acquired, will afford them support and satisfaction through life.

The dissemination of these improvements and inventions is extremely wanted by the poor. Nothing can be more comfortable than their present system of diet in many parts of England: nothing more wasteful than their application of fuel for warming and tempering the air in their cottages; that being an article, the too general want of which is the source of those petty pilfering habits among the poor, which often lead to atrocious crimes. The affixing and encouraging the domestic economy and management of the cottager, and the promotion of his comfort so as to give him more benefit and enjoyment from the means of life which his situation in society affords him, and the improvement of the general system of those public buildings with which the poor are concerned, will be among the most useful and important objects of the models to be exhibited at the institution. These will consist of improved fire-places and kitchens, and of flues and *lourers* for supplying rooms either with tepid or fresh air; so as to produce a considerable saving in the quantity of food and fuel consumed, either in cottages, or in public establishments; and materially to increase the health and well-being of those of our fellow-subjects, whose employment or situation obliges or induces them to continue the greater part of their time in close and crowded rooms.

But we shall better succeed in conveying an adequate idea of the plan of this admirable undertaking, by the following extracts from the *Prospectus*, and from a subsequent *Report* of its progress, published by order of the managers, dated May 25, 1801. The former of these will shew its beginning, the latter its progress, and the eagerness of the public to embrace a proposal so manifestly calculated for the benefit and the prosperity of the country at large.

“The pre-eminence of any people in civilization ought ever to be estimated by the state of industry and mechanical improvement among them. This is proved by an immediate reference to the experience of all ages and countries, where successful exertions having given courage to the spirit of invention, the sciences have flourished; and, according to the increase of the moral and physical powers of man, improvements have been made, which, in an earlier state of society, would have been deemed altogether visionary. Printing, navigation, and the useful and extended powers of the steam-engine—inventions, the practical excellence of which we all know and acknowledge, and the future effects of which can scarcely yet be conjectured—offer irresistible proofs of this; and it is to remove those causes which yet impede the progress towards perfection of those and other arts material to the accommodation of man, that the Royal Institution is set on foot.

“The slowness with which improvements of every kind are adopted, especially such as are calculated to be of general utility, is very remarkable. Besides the prejudices of individuals, and the power of habit, which attaches them to what has the sanction of universal practice, the supporters of this undertaking have to contend with many other circumstances equally unfavourable to the introduction of improvements. Some persons overlook them through mere indolence; some are disgusted with the very proposal of any thing new, and are ashamed and mortified that they should be deemed ignorant of what they long had supposed themselves perfect masters; some, who even submit to be instructed, work too awkwardly with tools to which they have been unaccustomed, not to tire of their business, their teacher, and his doctrines,

before they arrive at the object of their pursuit. But another cause, which occasions little attention to be paid to those who propose improvements, is a supicion of interested motives, which, indeed, is often but too well founded. Thus the most meritorious exertions to promote the public prosperity are either received with indifference, or viewed with suspicion: and many, even of those who are convinced of the excellence of what is proposed, are deterred by motives of jealousy, or envy, from promoting its success.

"These are the chief causes which prevent the reception of valuable inventions already known, and of such as the ingenious might otherwise bring forward to public notice. But another serious obstacle arises from that sub-division of labour which naturally takes place where active industry and the security of property are established; and from which happens, that almost every man becomes confined to some appropriate occupation, seldom knowing, or caring, what may be the processes to which the material of his trade may be subjected, before or after his art has been exercised on it; and still less aware of what is done in other trades or manufactures. The attention of these individuals is wholly engaged in the acquisition of wealth; and hence it is, and from a natural fear of pecuniary risk, that the generality of manufacturers possess neither the knowledge, the inclination, nor the spirit, to make improvements.

"Among the various classes of civil society, one which performs a great and very essential part of the general work is the class of philosophers, who have devoted themselves to the labour of observing, comparing, and inventing, and who engage in the development of truth by those remote analogies which escape the vulgar mind. But though invention and discovery are peculiarly their province, it may justly be doubted whether their moral and intellectual habits are calculated to produce useful practicable improvements. This kind of knowledge, indeed, no less than the stimulus of interest, and the capital of the manufacturer, are with them altogether wanting; while the latter, on his part, stands no less in need of the general information and accurate reasoning of the man of science. The great object, therefore, is to benefit the community by bringing to a salutary point of union the talents and means of both these descriptions of men.

"Three direct methods suggest themselves for the removal, or diminution, of the difficulties stated above: 1st, To give premiums to inventors, which is already done by the society for the encouragement of arts, &c. 2dly, To grant temporary monopolies, which is done by the grant of patents. 3dly, To diffuse the knowledge, and facilitate the introduction of useful mechanical inventions and improvements, which is proposed to be done by the Royal Institution.

"In the house [purchased in 1799, in Albemarle-street, London, by the managers] it is intended to exhibit to the public the completest working models, or contrivances of the full size, of all such new and valuable inventions as are capable of being applied to the common purposes of life. By this arrangement, those who adopt them may readily determine, if any failure happen in their experiments, whether the mistakes of workmen, the management of servants, or the principle of the invention, have been the cause. Such a repository must also be of infinite use to artificers in furnishing models, and must enable every enquirer to obtain a thorough acquaintance with the nature and principles of what he wishes to imitate. Whatever is visible and tangible addresses itself more forcibly to the understanding than can be conveyed by any graphic or written description: it is not, however, intended to neglect the aid of the latter; and, accordingly, detailed accounts or descriptions, accompanied with suitable drawings, will also be exhibited by way of illustration.

"Arrangements will also be made, and correspondencies established, for obtaining a knowledge of new inventions, both at home and abroad. Visitations of manufactories, and examinations of various processes in the arts, are likewise intended; and to the growing mass of instruction, which may arise from these sources, the managers will add a library of all the best publications on the subjects for which this institution is established.

"For teaching the application of science to the useful purposes of life, a temporary lecture-room is fitted up for philosophical lectures and experiments; a complete laboratory and philosophical apparatus, with the necessary instruments, will be provided; and men of the first eminence in science engaged to officiate in this essential department. The machines and models will afford a perpetual source of instruction; and the lectures will be particularly useful to elucidate and apply those general principles which are only in part discernible in particular structures. The first principles of mechanics will be exhibited and explained in the simplest engines, called the mechanical powers; and, as connected with these, the practical operations of various arts will be regarded, and the mutual connection between the theory of mechanics, and the experimental knowledge of the materials. Under general mechanics will be shewn the advantages we derive from those happy expedients by which the labour of man is abridged in husbandry, and the various operations of art.

"Chemistry, with the aid of a laboratory and complete apparatus for the several processes, will be taught in the same simple and perspicuous manner; and this elementary knowledge, so indispensable to the intelligent manufacturer, will be connected with the great operations of the arts and of trade.

"From the vast field of individual operations or separate manufactories, the enquirer will be led to other works of more general consideration, which include not only the objects of mechanics and chemistry strictly taken, but likewise those of commercial operation and political economy. Under this class of objects will be found the structure of roads and forms of vehicles; the establishment of canals; the improvement of rivers, harbours, and coasts; the art of war, and various objects connected with it. In the course of these enquiries, the exhibition of working models will particularly display the powers of hydraulic machines, and that striking useful apparatus the steam-engine.

"But, above all, we shall find our contemplations urged to the phenomena of light and heat, those great powers which give life and energy to the universe! powers which, by the wonderful process of combustion, are placed under our command indeed, but of the advantages of which we do not half avail ourselves."

Having thus given, as much as at large as our limits will allow, an account of the rise of this truly grand public undertaking, we shall here add a few particulars from the last report, with a view of shewing its present state.

"The Institution," says the report, "is now placed on a most respectable foundation; and although none of the details of this great and extensive establishment are quite completed, yet enough has already been done to shew that it must soon become extremely interesting, and very useful; and that it will long remain, — an ornament to the metropolis, — and a proud monument of the energy — wealth — and liberality — of the private individuals of the British nation.

"In the infancy of the establishment, before the Institution had acquired a visible form, and adequate support, it was natural to expect that some doubts would be entertained, even by the most sanguine, of the possibility of completing so great a public undertaking, by the mere voluntary exertions of private individuals."

tions of individuals; but all grounds for such doubts are now happily removed. The permanent existence of the Institution,—and even as a *body politic and corporate*,—has been secured by the authority of a *Royal Charter*; and the establishment has been taken under the immediate patronage of *his Majesty*.

"The lists of the proprietors and subscribers to the institution contain the names of many of the most illustrious characters in this country; and the money subscribed to carry the proposed plans into execution amounts already to a sum almost incredibly great—to 23,200*l.*; and this, exclusive of 7000*l.* generously offered by a small number of the proprietors (but which will not be wanted); for enabling the managers to defray the expences of erecting the new buildings.

"Upon settling the accounts, and calling in, and paying off, all debts outstanding against the Institution, up to the first day of the present month, it was found, that a sum amounting to above 10,800*l.* then remained at the disposal of the managers; which sum will, no doubt, be quite sufficient, not only to defray all the expences of finishing and furnishing the buildings of the Institution, in all their numerous and extensive details, but also for fitting up all the workshops; and providing them with tools, and a stock of materials for work.

"The house and premises, which have been purchased for the Institution, are extensive; the ground covered by the principal edifice having originally been allotted for building four houses for private families; and no situation could have been found, in this metropolis, more convenient, or better adapted to all the purposes of this public establishment.

"Professors and lecturers in natural philosophy, chemistry, and mechanics, have been engaged; and lectures are now given, daily, in two spacious lecture rooms; the one capable of containing 300, the other 600, persons.

"A spacious and most complete chemical laboratory has been built, and is now furnishing with all the implements and apparatus necessary for carrying on, upon a large scale, all the various processes of practical chemistry; and chemical analysis; and for making new and interesting experiments. A director of the laboratory has been appointed, and also a chemical operator; and the managers are now in treaty with a very ingenious German chemist, whom they hope to engage, as an assistant in the laboratory, and who will devote his whole time to the business of it.

"The workshops of the Institution, where models, &c. of new and useful inventions will be constructed, and sold at reasonable prices, to such proprietors and subscribers as may apply for them, are quite finished; and are now furnishing with the most complete sets of tools that can be procured.

"A master of the workshops has been engaged, who is himself a working mathematical instrument maker and model maker; and will have the care of all the philosophical apparatus belonging to the Institution, and keep it constantly in repair and ready for use. He will reside in the house, and superintend and direct all the workmen who are employed in the workshops;—he will likewise superintend and instruct all such ingenious and well-behaved young men as may, at the recommendation of proprietors, be admitted into the workshops of the Institution, to receive instruction, and to complete their education in any one or more of the mechanic arts.

"The following workmen are already engaged for the workshops of the Institution, viz. A mathematical instrument maker.—A model maker.—A cabinet maker.—A carpenter.—A worker in brass and copper.—A tin-plate worker; and

an iron-plate worker. To these will soon be added bricklayers and stone-masons; who will be instructed, and enabled to instruct others, in setting new-invented fire-grates, roasters, ovens, boilers, &c.

"A complete kitchen, for a small family,—with a small roaster, on the most simple construction—a cottage fire-place grate—and a small boiler with steamers,—has been put up in the housekeeper's room; and may be examined by all those who frequent the house of the Institution.

"The principal kitchen will contain roasters, ovens, boilers, steamers, &c. on the newest and most approved construction; and, in order that the proper method of managing them may be seen, they will be kept in daily use, and persons will attend to them.

"In order that the proprietors and subscribers may be enabled to judge, from actual experiment, of the merit of any new method of cooking, or of any new dish that may be proposed, a *dining-room* has been built, and will soon be ready for use, at the house of the Institution, in which the managers will, occasionally, order *experimental dinners*, to which the proprietors and subscribers will be invited, in as far as the accommodations will admit; the expence of such dinners to be defrayed by those who partake of them."

To render the house of the Institution more pleasant, an additional room has been set apart for their private and exclusive use:—This has been called the *conversational room*; and to render it still more useful and agreeable, it will be furnished with a collection of good maps; and, as soon as some necessary previous arrangements (which are now actually making) shall be finished, those who frequent this room will be furnished, at the most reasonable prices, from the housekeeper's room below, with soups of various kinds—tea, coffee, chocolate, and other refreshments. Besides these, other accommodations for the proprietors and subscribers are provided, as the opportunity of writing letters; and a general and two-penny post for their conveyance.

"A complete Printing Office, with a press, types, and every other instrument and implement necessary in printing, has been established at the house of the Institution; and a Printer is engaged, and has for some time past been constantly employed in printing for the Institution. It is expected that the printing of the journals of the Institution, which in a few months will begin to appear at regular intervals, probably once a week, will give full employment to this press: for as these journals will contain not only an account of all that is doing at the Royal Institution, and in the country at large, to introduce new and useful inventions and improvements, but will also contain selections from all the newest foreign scientific journals, and other scientific publications, which will all be regularly taken in at the Royal Institution, there is no doubt but that the Journals of the Royal Institution of Great Britain will become one of the most interesting and most useful periodical works that has ever appeared in any country; and, consequently, that they will be much sought after, and much read.

"The reports of the various committees, for specific scientific investigations (which will soon be appointed by the managers), will, no doubt, furnish much interesting matter for the Journals of the Institution."

All the principal scientific periodical publications, foreign and domestic, the transactions of learned societies, &c. are regularly taken in, and laid on the table in the reading-room the moment they arrive.—All the daily English newspapers are taken in, in like manner, and perused, in a separate apartment, by the subscribers.

In a second reading-room, which is spacious and airy, are elegant book-cases, and library tables; and, as it is furnished

with double windows, and thin white window blinds, it is uncommonly quiet and pleasant as a reading-room, though it is situated on the ground floor, and near the street. The carriages which pass are scarcely heard through the double windows; and as the blinds prevent its being overlooked from without, it has an air of stillness and retirement which is very striking, and very pleasant to those who frequent it.

Many valuable books have been presented to the library of the Institution, and it was not till all the book-cases in the room were filled by these generous contributions, that new book-cases were provided. All books proper to appear in a public library, those only excepted which are professedly on political questions, are received by the managers, and their thanks are returned for them.

As the Royal Institution was specially designed for promoting *mechanical* improvement, and exciting and encouraging *practical* ingenuity and *useful industry*, the investigation of all subjects lying within the provinces of either of the *three learned professions* are justly avoided; consequently, all discussion relative to *religion, law, and medicine*, is declined.

One of the most interesting details of the Institution still remains to be mentioned:—It is the *repository*. The measures necessary for forming it have not been neglected, but, from its nature, it cannot be finished, nor indeed can it be begun, till the establishment is quite complete in all its other essential parts. Models of mechanical inventions and contrivances, in order to their being really useful, must be so made as to serve for imitation, consequently they must be constructed with the greatest care; and they cannot be made in the Royal Institution till those shops are fitted up, and furnished with the best tools, and the best workmen. These workshops will soon be completed, and properly manned; in the mean time, a spacious and elegant room, 44 feet long, and 32 feet wide, with the ceiling supported by two rows of columns, has been built for the repository, and in less than one month will be perfectly finished, and ready for the reception of the machines and instruments which it may be judged proper to exhibit to public inspection.

As soon as some addition to the buildings shall be completed, it is intended to accommodate a certain number of young men, of different mechanical professions, who, at the recommendation of proprietors, will be taken into the house to be instructed. These will be boarded and lodged in the house, and be employed in the workshops;—and for their improvement in drawing—practical geometry—and mathematics,—an evening school, under the direction of the clerk of the works, will be established in the house.

“As most of the young men who will be admitted into this seminary will probably come from distant parts of the country, and will return home, after a residence of three or four months at the Institution, carrying with them a perfect knowledge of such new and useful inventions, applicable to the common purposes of life, as may be deserving of being generally known and adopted, it is easy to foresee that this arrangement will be of great and extensive public utility. It is, perhaps, that part of the establishment precisely which will be the most interesting, and which will contribute the most powerfully to the attainment of the principal object of the Institution: “*The diffusing the knowledge, and facilitating the general introduction of useful mechanical inventions and improvements.*”

The funds of the Institution arise, 1st, from 60 guineas paid by each *hereditary subscriber*, who is named a *proprietor*; 2d, from 15 guineas paid by each *life-subscriber*; 3d, from three guineas paid by each annual subscriber; 4th, from particular donations and legacies.

A proprietor has an *hereditary transferable share* in the

house and all the property belonging to it, has a vote in the election of managers and visitors, and two transferable tickets of admission to the establishment and lectures. A *life-subscriber* has a ticket of admission for life, not transferable. An annual subscriber is entitled to a similar ticket during the continuance of his subscription. The three classes are alike open to ladies and gentlemen, and every class of subscribers has the privilege in common of having copies of models or drawings made (at their own expence) from those belonging to the Institution.

The lectures are, 1st, a course of *experimental philosophy*, comprehending the principles of astronomy, electricity, magnetism, mechanics, hydrostatics, pneumatics, and optics. In this course all abstract and mathematical reasoning are avoided, and the whole calculated at once to instruct and amuse. 2d, A course of *chemistry*, in which the principles of the science and the modern discoveries are illustrated by experiments, and its application to the arts and manufactures, &c. shewn. 3d, An evening course, calculated for persons mechanically and scientifically engaged, in which the foregoing subjects are minutely and *technically* treated.

“The number of the proprietors of the Institution (1802) amounts to 325;—the life-subscribers to 268;—and the annual subscribers to 527;—making in the whole 1120 persons, who have already come forward in support of this great public undertaking.—This number is undoubtedly very great, but the lists of the members of the Royal Institution will appear doubly respectable when the many distinguished names which dignify them are taken into consideration. But if so many persons of great abilities,—high rank,—and most respectable character,—could be found to come forward and support an undertaking, not only unfinished, but new in its kind, and of the success of which doubts might well be entertained, we may safely look forward with confidence to a period, not far distant, when the Royal Institution of Great Britain, completed in all its details, and in full activity, will become so interesting, that every person of liberality and discernment, who takes pleasure in contemplating the progress of human improvement, will be desirous of belonging to it, and willing to assist in promoting its permanent prosperity.”

INTERLACHEN, a town of Switzerland, capital of a bailiwick of the same name, in the canton of Bern. It is seated between the lakes of Brienz and Thun, 28 miles S.S.W. of Lucern, and 32 S.E. of Bern.

INTERFERING, in farriery, a local disease incident to horses. It arises from various causes; and though this malady is sometimes constitutional in the animal, yet it is more frequently occasioned by an improper method of shoeing; in consequence of which the horse moves his hind feet so closely together, that hard scabs are gradually formed by their continual friction, and the disorder at length is attended with halting or lameness.

According to Professor Bradley, *interfering* may be cured by a compound made of three parts of fresh sheeps' dung, and one part of rye or wheat flour, well dried.—These ingredients should be formed into a cake, then baked in an oven, and applied warm to the part affected, which will thus speedily heal; or, it may be anointed with a mixture of turpentine, and verdigrease finely pulverized, by the use of which the scabs in general shortly disappear.

INVERESK, a village in Edinburghshire, situate on the E. side of the mouth of the Esk, on the Frith of Forth. In 1783, the subterraneous remains of a Roman hot bath were discovered here.

INVERBURY, a borough in Aberdeenshire, situate on the fertile banks of the Don, just above its confluence with the river called Urie Water. It is 15 miles N.W. of Aberdeen.

JOACHIMSTHAL, a town of Bohemia, celebrated for its silver mines, which are the best in the kingdom. It is 52 miles S.E. of Dresden.

JOCKGRIM, a town of France, in the department of Lower Rhine, situated on an eminence, near the Rhine, nine miles S.E. of Landau. Long. 8. 16. E. Lat. 49. 13. N.

JOHANNESBURG, a town of Eastern Prussia, with a citadel, seated on the river Pech; near the lake Spirding, 95 miles S.E. of Königsberg. Long. 22. 39. E. Lat. 53. 16. N.

JOHN, Sr. one of the Philippine islands, E. of Mindanao. Long. 126. 32. E. Lat. 9. 30. N.

JOHN, St. a river of New Brunswick, which, running from N. to S. enters the bay of Fundy, at the city of St. John's.

JOHN, St. a city of New Brunswick, situate at the mouth of the river St. John, in the bay of Fundy. Long. 65. 15. W. Lat. 45. 12. N.

JOHN, St. a town on the E. side of the island of Newfoundland. It has a good harbour, entirely landlocked, and defended by several forts, in one of which the governor of the island resides. —Long. 52. 21. W. Lat. 47. 32. N.

JOHN, St. the capital of Antigua. It is one of the most regular towns in the West Indies, and has the most commodious harbour in the Leeward Islands. Long. 62. 4. W. Lat. 17. 4. N.

JOHNQUERA, a town of Spain, in Catalonia, seated at the foot of the Pyrenæes, 20 miles S. of Perpignan.

JOHORE, **JOR**, or **INOR**, a town of the kingdom of Malacca. It was destroyed by the Portuguese in 1603, but has been rebuilt, and is in the possession of the Dutch. Long. 93. 55. E. Lat. 1. 15. N.

JONESBOROUGH, a town of Tennessee, capital of the district of Washington, seated near the foot of the Iron mountains, 80 miles E. by N. of Knoxville. Long. 82. 46. W. Lat. 36. 8. N.

JONKIÖPING, a town of Sweden, capital of the province of Smoland, and seat of the parliament, or superior court of justice for Gothland. The houses are chiefly of wood, covered with turf or moss; no thatching being used, as both too dear and too dangerous in case of fire. In order to keep out the rain, large layers of birch bark are spread over the timber-work of the roof, under the covering of turf or moss. These turf roofs make a singular appearance, many of them producing herbage, which is occasionally cut for the use of the cattle; and a few are ornamented with flowers. The town is seated on the S. end of the lake Wetter, with a strong citadel, 50 miles N.W. of Calmar. Long. 14. 46. E. Lat. 57. 12. N.

JORDAN, a river of Palestine, which rises in Mount Libanus, and runs from N. to S. forming two lakes, the one formerly called the Sea of Galilee, or the lake of Tiberias, and the other, the Dead Sea.

JOSEPH (II.) Emperor of Germany. The genius of this emperor was active and prompt, but vehement and impetuous, and embracing too many objects at the same time. He was superficial in all his acquisitions, and though anxious to learn every thing, he mastered nothing. He possessed magnanimity, and, in despite of detraction, his heart was open to the impressions of sensibility; and if he often refused to assist the suffering individual, it was because he wished to reserve the means of exercising his beneficence in favour of the unfortunate in general. Never was he really inexorable but towards those who transgressed the laws, and even then the public good was the motive of his severity; his actions were rather the result of principle than inclination. He has been reproached with aggravating punishments, and modifying

decisions to the caprice of his own arbitrary will. Without meaning to justify him in this particular, we may allege the uprightness of his intentions, which designed to intimidate by example, and to prevent lenient or corrupt judges from securing the guilty from punishment; and, above all, his profound ignorance in points of jurisprudence, which continually led him to mistake the bounds of his own power. To the same cause we must attribute his enterprises against the property and the privileges of the citizens; of which there can not be a stronger proof than the surprise he testified on many occasions, when the clamours of the public, and the opposition he met with, convinced him of the discontent of his subjects.

Few princes have been inflamed by a stronger passion for the good of their people, and none have been occupied with more activity and zeal about the means which he esteemed proper to promote it. This pursuit was so predominant, that it absorbed all others; and he was so devoted to the weighty cares of government, that every instant of his life he was the monarch, and had scarcely time to know that he was a man; thence it was, that he had none of the weaknesses which so often dishonour princes, and oppress their subjects. He was a prey to no ruinous whim, to no mistress who exhaust the state, and consign its employments to unworthy hands. Simple in his manners, and inimical to luxury of any kind, he erected no palaces whose foundation rested upon the shattered fabric of the poor man's cottage. How then, it may be asked, did it happen, that though possessed of these rare virtues and qualities, his reign should be marked with a series of calamities? The fact, it will be said, is not astonishing when we recollect that he was generally superficial, was cursory in all his observations, drew false consequences from every thing he saw, and built upon them a plan of reformation which was as defective as the principles upon which it was founded. This is, indeed, the opinion of many of his judges, but cannot be adopted by such as will take the trouble of discriminating between what he did, and what he wished to do. It is true that the education of the emperor left his natural genius destitute of cultivation, and that wandering at hazard, and destitute of principles to guide it, he must have been often deceived; but these defects, it must be acknowledged, were, to a certain point, corrected by nature, in bestowing on him an accuracy of judgment, and a facility of conception: he readily discovered the abuses which were consecrated by the prescription of custom; he knew the abilities and the necessities of the state, and the means to be employed to raise it to the degree of prosperity and power of which it was capable. If he failed in his endeavours, we should be wrong to conclude that his views were ill directed, or that his theory was incorrect; but a variety of prejudices, fatal to his happiness and to our own, led him astray in the execution. The most excessive partiality cannot refuse to his designs the tribute of admiration which they justly merit.—They were such as required a man of superior powers to form, and to dare to accomplish them. They were intended to unite in the same political form of government the various provinces of the monarchy; to incorporate into one people, twenty nations, differing in their laws, customs, and languages; to purify their morality and religion, by determining invariably the principles on which both were to be practised and preached; to increase useful knowledge, by multiplying and improving the public schools; to encourage commerce, by exciting and protecting the national industry; to ensure the progress of agriculture, by ameliorating the lot of the husbandman; to unite to the state, by means of toleration, citizens who had been alienated from it by their religious opinions; in a word, to make of the monarchy one consistent whole, the parts of

which being well connected, should render it powerful and happy at home, respected and formidable abroad.

Such was his design, which certainly was in itself at once great and judicious. The obstacles which might offer themselves in the execution were not of a nature to resist the effort of a dextrous hand to prevent, or at least to remove them; and it is not to be doubted that an absolute prince, who had united to the power of rendering himself formidable, the talent of making himself beloved; who had associated to his enterprises men whose capacity and probity might have fixed the public esteem; would have succeeded in surmounting them, with the aid of time and the wisdom of his measures. Unfortunately no monarch was ever less capable of employing those means. Vexatious by constitution, he was still more so by his mode of reasoning; persuaded that if he did not precipitate the reforms which he projected, he would not have time to complete them, the most violent measures were ever those which he preferred. In vain was it represented to him, that this was the most improper method to produce the effect which he promised himself; his self-confidence confirmed him in his obstinacy, and made him despise these prudent counsels. To this fault was joined his extreme mistrust, which induced him to discover in those whose rank attached them to his person, or whose office destined them to share with him the charge of the government, so many secret enemies of the good cause which he espoused; who were seeking their own fortunes, and disposed to sacrifice the interests of the public to their private emolument. This supposition, as false in its principle as dangerous in its consequences, alienated the affections of his subjects, and raised a barrier between the prince and those whose abilities might have corrected his own ideas. We cannot then wonder at the invincible perseverance with which he pursued any ruinous or chimerical project, notwithstanding it might be opposed by the united voice of the whole kingdom. Convinced that the more he sought to promote the general good, the more obstacles private interest would raise against him; he almost always judged of the excellence of his designs, by the degree of resistance which he experienced to their execution. Another consequence of this principle was, that not being able to confide, without danger, to any one the care of fulfilling his wishes, he was forced to undertake it himself; and by being at once the proprietor and the agent, he must do every thing in order to its being well done. From this complicated delusion it followed, that he deprived himself of the means of concluding any thing; and that, by continually destroying what he began, he could never raise the fabric which was to supply the place of that he had overthrown. His mind, oppressed by the weight and multiplicity of business, was lost in the labyrinth he had created, and forgetting to-day the decrees which had been yesterday published, he was perpetually contradicting himself. The number of opposite edicts of his reign prove the fact, and added contempt and ridicule to the discontent which his administration inspired, in despite of the best intentions. In the design of correcting abuses, he successively directed his endeavours against all the orders of his subjects: beginning with the clergy, whom he rendered contemptible without amending, he passed to the commercial class, whom he crushed under the weight of prohibitory laws; and from them to the nobility, whom he completely ruined, under pretence of relieving the husbandman, who found no redress from his changing, misplacing, and perverting every thing. He affected to despise what he called prejudice, and violated without scruple the most sacred contracts which subsisted between prince and people. So many violent acts, whose motive may render them excusable in the eyes of God, but not in those of men, and especially of those who were the victims of them,

Vol. X.

drew upon him so general a hatred, that it would be difficult to ascertain the extremities which might have followed, if that power who watches over the preservation of the monarchy, had not terminated its evils, by removing its author. The emperor died, but his expiring regrets could not reconcile him to a people oppressed by vexations of every kind, by a ruinous war, and by the loss of the finest province of the monarchy. May this instructive example of Joseph II. bring conviction to the minds of princes, of the difficulty of governing with propriety, though with the advantage of the most brilliant qualities of the heart and understanding; of the essential necessity of repressing their pride, and gaining the affections of their subjects; and if there should arise any of his successors who might be tempted to tread in his steps, let him recall to mind his wretched fate, and, by avoiding rash innovations, permit the state to experience that repose which is so necessary to its well-being.

JOSELIN, a town of France, in the department of Morbihan, 25 miles N.E. of Vannes. Long. 2. 23. W. Lat. 48. 0. N.

JOURE, a town of France, in the department of Seine and Marne, with a late magnificent Benedictine abbey, 10 miles S.E. of Meux, and 35 E. of Paris.

JOYEUSE, a town of France, in the department of Ardeche, seated on the Baune, 27 miles S.W. of Privas.

IPHOFEN, a town of Germany, in the bishopric of Wurzburg, 15 miles E.S.E. of Wurzburg.

IPS, a town of Germany, in the archduchy of Austria, situate near the confluence of the Ips and Danube, 48 miles W. of Vienna. Long. 15. 11. E. Lat. 48. 13. N.

IPSALA, a town of Turkey in Europe, with a Greek archbishop's see. Near it are mines of alum. It is seated on the Larissa, 20 miles S.W. of Trajanopoli, and 118 W. of Constantinople. Long. 26. 10. E. Lat. 40. 57. N.

IPSERA, a small island in the Archipelago, in the form of a heart, 15 miles N.W. of the island of Scio. To the W. is another small island, called Anti-Ipsera.

IPSHEIM, a town of Germany, in the principality of Culmbach, 17 miles N.N.W. of Anspach.

IRAC-ARABIA, or **BABYLONIAN-IRAC** (the ancient Chaldaea), a province of Turkey in Asia; bounded on the W. by the desert of Arabia, on the N. by Curdistan and Diarbeck, on the E. by Irac-Agemi and Kufistan, and on the S. by the gulph of Persia. It is watered by the Euphrates and Tigris; and is almost all under the dominion of the Turks. Bagdad is the capital.

IRAC-AGEMI, or **PERSIAN-IRAC**, a province of Persia; bounded on the West by Irac-Arabia and Kufistan, on the North by Aderbeizan and Ghilan, on the East by Coushestan, and on the South by Faristan. Ispahan is the capital.

IREBY, a town in Cumberland, with a market on Thursday. Many Roman antiquities have been dug up here. It is seated in a valley, at the source of the river Eilan, 10 miles N.E. of Cockermouth, and 299 N.N.W. of London. Long. 3. 18. W. Lat. 54. 50. N.

IREKEN, **JERKIN**, or **YARKAN**, a rich and populous town of Tartary, the capital of Bocharia, with a castle. It is the staple town of all the trade carried on between India and the North part of Asia. The Kalmucks are masters of it; and never disturb any one on account of their religion. It is eight miles N. of Cathgur. Long. 73. 25. E. Lat. 41. 40. N.

IRJAH, a town of Hindoostan Proper, in the country of Cabul, 46 miles S.E. of Cabul. Long. 69. 8. E. Lat. 33. 50. N.

IRKUTSK, the largest and least populous government of 9 Q.

Russia, comprising all the E. part of Siberia, from the Northern Ocean to the frontiers of Chinese Tartary, and from the boundaries of the government of Tobolsk to the Eastern Ocean. This large territory was gradually conquered and appropriated by the Russians in their desultory excursions from Tobolsk. It is divided into the four provinces of Irkutsk, Nertskhuk, Yakutsk, and Okotsk.

IRKUTSK, a town of Russia, capital of a government of the same name, and the see of a Greek bishop. It is situate on the lake Baikal, and is a place of considerable commerce, the caravans which trade to China passing through it. Long. 104. 58. E. Lat. 52. 4. N.

IRON-ACTON, a village in Gloucestershire, at the conflux of the Staure and Laden, which form the river Frome, three miles from Bristol. Much iron has formerly been dug up, and many iron works and great heaps of cinders are to be seen here.

IRRIGATION (*Encycl.*). The principal object in irrigating the soil, is a proper supply of water; and, if that fluid abound with mud, the land will be more permanently improved, than by conducting a clear spring over its surface: hence it is certain, that if the liquor collected in farm-yards, the washings of different sinks, ditches, and the drains of the contiguous fields, could be conveyed into the common stream, the water would acquire a more fertilizing property.

But, in order to manage this important branch of rural economy with success, it will be requisite previously to ascertain, whether the stream will admit of a temporary weir or dam being constructed across it; whether the water can be raised to such a height as to overflow a particular spot, without injuring the contiguous land; and whether it can be drawn off with the same facility as it is conducted on the soil. If these objects can be attained, the process of irrigation may be undertaken in the following manner:

When the descent cannot be determined with tolerable precision by the eye, an accurate level of the ground must be taken, and the most elevated part compared with the height of the stream to be employed. The instrument used for this purpose, is called a *water-level*; and, as the common machines are but imperfectly adapted to the purpose, we have given in Pl. 33, the representation of a simple implement for taking levels, contrived by Dr. James Anderson; as it has been recommended to the notice of the public, by the Board of Agriculture.

It consists of two legs of common deal, A and B, about twelve feet in length, which are joined together at the top, and connected below by a cross bar, as delineated in the plate. From the angle at the top, a plummet, C, is suspended by a small cord; which, when a mark is made in the middle of the connecting bar, and the two legs are perfectly straight, will strike such mark, so that the level may be easily ascertained.

In the practical use of this instrument, Dr. Anderson directs a wooden pin, on which one of the legs of the frame may rest, to be driven into the ground at the level of the water, where the irrigation is intended to commence. The other leg is then to be brought round, till it touch the ground, on a level with the top of such pin, when another is to be driven in. After the level has in this manner been perfectly adjusted, the last-mentioned pin is to be employed as a rest for one foot, and the other turned about, till the level is found in the same manner. Thus, the precise direction which the stream should take will at once be discovered, without any trouble, or incurring any additional expence by digging through heights or filling up cavities.

The level being taken as directed, a wide ditch is to be cut as near to the dam as possible, that the water may be

conveyed to the highest part of the meadow; the sides and banks of the ditch being uniformly kept at an equal height, and elevated about three inches above the surface. Where the meadow is extensive, and the soil uneven, it will be necessary to have three works or dams in different directions, each of which should be five feet in width, if the meadow contain fifteen acres; and the highest part be the most distant from the stream. A ditch, ten feet wide, and three in depth, will, in general, be fully adequate to overflow ten acres of land; and if there be three works or dams in a meadow, and *flood-hatches*, or flood-gates, be placed at the mouth of each, when the water is not sufficient to irrigate the whole soil at once, it may be performed at three different periods; by taking out one of the hatches or gates for the space of ten days, at the expiration of which it is to be let down; and the other two taken up alternately for a similar period: thus each division will receive a proper share of water in its turn, and derive from it equal benefit.

Where the fall of the meadow renders it practicable, the bottom of the first work should be made as deep as the bed of the river; because the water, in proportion to its depth, will carry a larger or smaller quantity of mud with it, and consequently fertilize the soil in a more or less effectual manner. Small ditches, or troughs, ought likewise to be cut from the works at right angles, about 12 yards apart from each other; and their breadth should be adequate to the distance to which the water is to be conveyed: thus a trough two feet in width, and one foot deep, will irrigate a surface twelve yards wide, and forty feet in length.

It will, however, be requisite to provide the ditches with occasional flood-gates or sluices, especially when the water is rapid, in order to keep it sufficiently high to flow through the perforations in the gates, or over the sides. Between every second trough, a drain is to be cut at equal distances in a parallel direction, and of a proper depth for receiving all the water which overflows the adjacent lands, and conducting it to the principal drain with such rapidity, as to keep the whole stream in constant motion. For, if it be suffered to stagnate, it will be productive of the worst consequences; as the turf would become rotten, the soil be soaked without being ameliorated, and the land produce only coarse grass, rushes, or other aquatic weeds.

Where the meadows are cold, flat, and swampy, the width of the bed, that is, of the intermediate space between the trough and drain, ought never to exceed six yards. In such cases, the land cannot be too much intersected, especially when there is an abundant supply of water. The fall of the bed in every meadow ought to be in the proportion of one inch to each foot; for a rapid current always contributes to produce fine and sweet herbage; but the water ought never to flow more than two inches, nor less than one inch deep, except during the summer months.

Such is the method of irrigation practised in Gloucestershire, and likewise, with very few variations, in the counties of Wilts, Dorset, Cambridge, Hants, &c. Its advantages, indeed, are so important that, we trust, no rational agriculturist will hesitate to adopt the practice of floating land, throughout Britain, in every situation where a command of water can be obtained.—Common meadows are not only enriched, but those of a swampy nature are consolidated by means of the mud conveyed on them. They are also protected from the effects of frost by the flowing water, or by the ice when it is frozen; hence the roots of grass remain unaffected by the cold, and excellent crops are thus produced so early, as to be of intimate service for spring food, before the natural grass appears.

By irrigation, good pasturage may be procured in the be-

ginning of March; and, if the season be mild, much earlier. This crop is particularly excellent for feeding such cattle as have been *hardly* wintered, and so great are the benefits attending the flooding of lands, that the farmers of Gloucestershire are enabled to commence the making of cheese, at least *one month* earlier than those who do not possess the same opportunity. The utility of watering land is still further evinced by this circumstance, that from the great forwardness of grass, the feeding between the months of March and May, is worth one guinea per acre; in June one acre will yield two tons of hay; and the *after-grass* may always be estimated at twenty shillings; whether the summer be wet or dry.—The expence of irrigation is computed at from 3l. to 6l. per acre.

Land may be floated at any period of the year. In the months of December and January, the chief care consists in keeping the soil sheltered by the water from the severity of frosty nights. It will, however, be necessary to expose the surface to the air every ten days, or fortnight, during the winter, by laying it as dry as possible for a few days; and to discontinue the flooding, whenever the land is covered with a sheet of ice.

In February, greater attention is required; for, if the water be suffered to flow over the meadow for several days in succession, a white scum will be generated, which is very pernicious to the grass; and, if the water be drawn off, and the land exposed to a severe frosty night, without being previously dried for a whole day, the greater part of the tender plants will be totally destroyed.

In the beginning of March, the grass on well-flooded meadows will, in general, be so forward as to furnish abundant pasturage; when the water should be drained for the space of a week, that the soil may become firm, before heavy cattle be allowed to graze on such land: these, however, if the season be cold, ought to be supplied with a little hay every night, during the first week.

In the month of April, the grass may be eaten down closely; but no cattle should be turned in later; as otherwise the crop of hay will be much impaired, the grass become soft or woolly, and consequently its value be considerably diminished.

In the beginning of May, the water is again thrown over the soil for a few days, in order to moisten it; but the practice ought on no account to be continued during the summer; for it has an unfavourable effect on the *after-math*; and produces in sheep feed on it, the disorder called the *rot*.

Many other advantages arise from irrigation, which have been stated in our original article; and those readers who are desirous to acquire further information relative to this interesting branch of rural economy, may also consult Mr. G. Boswell's *Treatise on Watering Meadows*, &c. in which the necessary implements, and terms employed in irrigation, are explained and illustrated with engravings; as likewise Mr. Wright's *Art of Flooding Land*, &c. where the subject is periphrastically treated, and objections are ably answered.

IRRITABILITY (*Encycl.*). We have already stated this term to denote that essential property of animals, in consequence of which their fibres, on being touched, contract or become short, in a greater or less degree.

Chemists have lately endeavoured to shew, that not only animal, but *vegetable irritability* originates from the *oxygen* which is inhaled by the lungs, or respired by the leaves, or absorbed by the roots. And as respiration is every minute requisite to the support of animal life, Dr. Darwin conjectures that something immediately necessary to their existence, is acquired by the lungs of animals from the atmosphere, rather than from the food they digest; and that this nameless some-

thing, perhaps oxygen, is mixed with the blood, and again separated from it by the spinal marrow, after having undergone certain changes in the course of its circulation, or secretion. In a similar manner, he considers it as probable that the spirit of vegetation may be derived from that source, namely, the uncombined oxygen of the air, which is respired by the upper surfaces of the leaves, and not from that which is absorbed by roots, in a more combined state: further, that this oxygen is again separated from the juices by the *sejforium*, or brain, of each individual bud, after having undergone some change in its passage through the secretory vessels.

A long-continued, unusual, or unnatural stimulation of vegetable fibres, by an increase of heat, exhausts the spirit of vegetation: hence a slighter degree of cold, will destroy such fibres; because, after having been excited for a considerable time by a more powerful stimulus, they will cease to act on the application of one that is weaker, so that in consequence of hot days, tender plants are more liable to perish from the coldness of the night. For this reason, gardeners in the more northern climates, shelter both the flowers of apriots and the tender vegetables, during the spring-frosts, from the meridian sun, as well as from the destructive cold of the night, which is generally the most intense about one hour before sun-rise.

In the hot days of the month of June, 1798, Dr. Darwin twice observed several rows of garden-beans to become quite sickly; and some of them even died, in consequence of being irrigated for one or two hours with water from an adjoining canal. This circumstance he attributes to the sudden application of cold, after the plants had been greatly enfeebled, and deprived of their irritability by the excessive heat of the season, rather than to the too copious watering of the dry soil. Some vegetables, however, such as strawberries, onions, &c. which were equally exhausted, are less liable to be thus injured, and even receive benefit from occasional irrigation in dry and sultry weather.

On the contrary, the spirit of vegetation acquires additional vigour, if plants have been exposed for a considerable time to a less than usual degree of heat; but, if they be suddenly removed from a cold to a warm place, they will experience a similar fate with those hapless persons, to whose frozen limbs sudden heat was imprudently applied: thus, too great increase of action occasions inflammation, which is generally succeeded by mortification and death. This fact has been ascertained and confirmed by the experiments of M. Van Ullar, who kept two species of the spurge, or wartwort, namely, the *Euphorbia Pepsus*, and *Ejula*, L. secluded from the light and heat, with a view to render them more irritable: on exposing these plants afterwards to a meridian sun, they became gangrenous, and in a short time decayed.

The increased, or diminished, degree of irritability in plants, is by Dr. Darwin attributed to their previous habits, with respect to the stimulus of greater or less heat. Thus, the periods at which vegetables thrive in the spring, appear to be greatly influenced by their acquired habits, as well as by their present sensibility to heat: hence potatoes will germinate in a much cooler temperature during the spring than in autumn; hence also, the vernal months are the most favourable to the process of making good malt; because the barley will then sprout with a less degree of heat than at any other season.

The irritability of plants has been discovered to be greater in the morning than at noon, and less in the evening than at mid-day; though it is considerably augmented during cool and rainy weather. In a similar manner, the limbs of animals acquire a greater sensibility of heat, after having been exposed to the cold; thus, the hands, after immersing

them for a short time in snow, glow with warmth on entering the house;—and the late celebrated Spallanzani observed several animals and insects, that conceal themselves under ground in a torpid state during the winter, and enjoy the genial warmth of the spring, again to disappear at a season when the heat of the atmosphere was much higher than on their first emerging from their subterraneous abode.
